May cause dizziness or light-headedness; request assistance with ambulation. Use caution performing tasks that require alertness (e.g. operating machinery, driving). ■ May cause a photosensitive skin reaction with exposure to sunlight. ■ Avoid pregnancy and consider birth control options. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category D: avoid pregnancy. Can cause fetal harm. Congenital anomalies, including limb reduction, retardation of skeletal development in the fetus and in infants, and bulging fontanels in infants have been reported. May cause permanent tooth discoloration and enamel hypoplasia when used during tooth development (last half of pregnancy, infancy, and childhood to the age of 8 years); see Contraindications and Precautions. ■ Discontinue breast-feeding.

Elderly:

Differences in response compared with younger adults have not been identified; however, caution and lower-end doses are suggested; see Dose Adjustments.

DRUG/LAB INTERACTIONS

May depress plasma prothrombin activity; concurrent use with **anticoagulants** (e.g., warfarin [Coumadin]) may require a decrease in the anticoagulant dose. ■ Bacteriostatic drugs may interfere with bactericidal action of **all penicillins** (e.g., ampicillin, oxacillin); avoid concurrent use. ■ May render **oral contraceptives** less effective; may result in pregnancy or breakthrough bleeding. ■ Risk of hepatotoxicity increased if used concurrently with **other hepatotoxic agents** (e.g., alcohol, amiodarone [Nexterone], carbamazepine [Tegretol], daunorubicin [Cerubidine], fluconazole [Diflucan], NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)], zidovudine [AZT, Retrovir]). ■ Fatal renal toxicity has been reported with concurrent use of **methoxyflurane** (Penthrane [an inhalation anesthetic]). ■ Avoid concurrent use of **isotretinoin** (Accutane) before, during, and after minocycline. Both drugs are associated with pseudotumor cerebri (benign intracranial hypertension in adults). ■ Concurrent use with **ergot alkaloids** (e.g., methylergonovine [Methergine]) increases the risk of ergotism (risk for vasospasm potentially leading to cerebral ischemia and/or ischemia of the extremities). ■ Potentially serious drug interactions may occur when IV magnesium sulfate heptahydrate, a component of minocycline for injection, is given concomitantly with **CNS depressants, neuromuscular blocking agents,** and **cardiac glycosides**. ■ May cause false elevations of **urinary catecholamine levels** with the fluorescence test.

SIDE EFFECTS

Incidence of side effects increased if given too rapidly or if recommended dose is exceeded. Numerous side effects have been reported, including angioneurotic edema, anorexia, arthralgia, asthma exacerbation, blood dyscrasias, blurred vision and headache (benign intracranial hypertension) in adults and bulging fontanels in infants, bronchospasm, CDAD, CNS toxicity (e.g., convulsions, dizziness, light-headedness, vertigo), cough, diarrhea, discoloration of secretions, DRESS, dyspepsia, dysphagia, dyspnea, elevation in BUN, enamel hyperplasia, enterocolitis, erythema multiforme, exfoliative dermatitis, fever, glossitis, hepatotoxicity (autoimmune hepatitis, hepatic failure [fatal], hepatic cholestasis, jaundice), hyperbilirubinemia, hypersensitivity reactions (including anaphylaxis), increased liver enzymes (e.g., AST, ALT), inflammatory lesions (with monilial overgrowth) in the oral and anogenital regions, injection site erythema and pain, interstitial nephritis, joint stiffness and swelling, lupus-like syndrome, myalgia, myocarditis, nausea, oral cavity discoloration (gums, lips, tongue), pancreatitis, pericarditis, photosensitivity, pneumonitis, polyarthralgia, pruritis, pseudomembranous colitis, pulmonary infiltrates with eosinophilia, renal failure (acute), serum sickness–like reactions, skin rashes, Stevens-Johnson syndrome, stomatitis, systemic candidiasis, systemic lupus erythematosus exacerbation, thrombophlebitis, tinnitus, tooth discoloration, urticaria, vomiting, vulvovaginitis.

Adverse effects that may be associated with magnesium intoxication include cardiac and CNS depression proceeding to respiratory paralysis, circulatory collapse, depressed reflexes, flaccid paralysis, flushing, hypotension, hypothermia, and sweating.

Overdose:

Dizziness, nausea, vomiting.

Post-Marketing:

Thyroid cancer with prolonged use.

ANTIDOTE

Notify the physician of all side effects. If minor side effects are progressive or if any major side effect (e.g., DRESS, lupus-like syndrome, serum sickness–like syndrome) or overdose occurs, discontinue the drug and treat symptomatically. Treat hypersensitivity reactions with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated or resuscitate as necessary. Mild cases of CDAD or colitis may respond to discontinuation of minocycline. Treat antibiotic-related CDAD or pseudomembranous colitis with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin). Not removed in significant quantities by hemodialysis or peritoneal dialysis.

MITOMYCIN BBW

(my-toe-**MY**-sin)
MTC, Mutamycin
Antineoplastic (antibiotic)
pH 6 to 8

USUAL DOSE

Pretreatment:

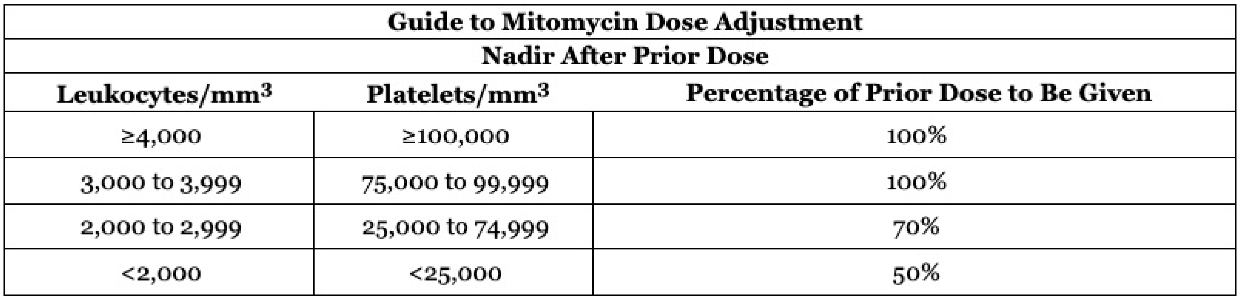
Baseline studies indicated; see Monitor. See Maternal/Child.

10 to 20 mg/M^2 as a single dose. May be repeated in 6 to 8 weeks after adequate bone marrow recovery; see Dose Adjustments. Discontinue drug if no response after two courses of treatment.

DOSE ADJUSTMENTS

Subsequent doses based on posttreatment leukocyte and platelet counts. Withhold dose for leukocytes below 4,000/mm^3 or platelet count below 100,000/mm^3. Adjust subsequent doses based on nadir after the prior dose according to the following chart.

■ Lower usual dose range is indicated when used with other antineoplastic drugs and radiation.



Guide to Mitomycin Dose Adjustment

Nadir After Prior Dose		
Leukocytes/mm^3	**Platelets/mm^3**	**Percentage of Prior Dose to Be Given**
≥4,000	≥100,000	100%
3,000 to 3,999	75,000 to 99,999	100%
2,000 to 2,999	25,000 to 74,999	70%
<2,000	<25,000	50%

DILUTION

Specific techniques required; see Precautions.

Each 5 mg must be diluted with 10 mL SWFI. Allow to stand at room temperature until completely in solution. May be given through Y-tube or three-way stopcock of a free-flowing infusion of NS or D5W or further diluted in either of the same solutions or sodium lactate ⅙ M and given as an infusion.

Storage:

Store unopened vial at CRT. Stable after initial reconstitution at room temperature for 7 days, up to 14 days if refrigerated. When further diluted to a concentration of 20 to 40 mcg/mL, it is stable at room temperature for 3 hours in D5W, 12 hours in NS, and 24 hours in sodium lactate ⅙ M.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

A single dose over 5 to 10 minutes.

Infusion:

Rate determined by amount and type of solution, typically 15 to 30 minutes.

ACTIONS

A highly toxic antibiotic, antineoplastic agent. Cell cycle phase–nonspecific, it is most useful in G and S phases. Interferes with cell division by binding with DNA to slow production of RNA. Rapidly distributed to body tissues and ascitic fluid. Does not cross blood-brain barrier. Metabolized primarily in the liver, but some metabolism occurs in other tissues as well. Some excreted in urine.

INDICATIONS AND USES

Treatment of disseminated adenocarcinoma of the stomach or pancreas. Used in combination with other drugs. Used intravesically in bladder cancer.

Unlabeled uses:

Combination chemotherapy in anal, cervical, head and neck, metastatic breast, and non–small-cell lung cancers and in malignant mesothelioma.

CONTRAINDICATIONS

Not recommended as single-agent primary therapy. Known hypersensitivity to mitomycin, thrombocytopenia, coagulation disorders, increased bleeding from other causes, potentially serious infections, SCr greater than 1.7 mg/100 mL.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities for monitoring the patient and responding to any medical emergency. ■ Use extreme caution in impaired renal function; see Contraindications. ■ Acute shortness of breath and bronchospasm have occurred within minutes to hours following administration of vinca alkaloids (e.g., vincristine) in patients who have received mitomycin previously or are receiving mitomycin simultaneously. Bronchodilators, steroids and/or oxygen may be used to treat respiratory distress. ■ Bone marrow suppression (leukopenia and thrombocytopenia) may be severe and contribute to overwhelming infections in an already compromised patient. ■ Hemolytic uremic syndrome (hemolytic anemia, thrombocytopenia, and irreversible renal failure) has occurred in patients receiving mitomycin as a single agent or in combination with other agents. It can occur at any time during treatment, but most cases have occurred with a cumulative dose greater than 60 mg. Administration of blood products may exacerbate the symptoms.

Monitor:

Monitor WBC, RBC, platelet count, PT, bleeding time, differential, and hemoglobin before, during, and 7 to 10 weeks after therapy. ■ Monitor all patients, especially those nearing a cumulative dose of 60 mg, for unexplained anemia with fragmented cells on peripheral blood smear, thrombocytopenia, and decreased renal function; see Precautions. ■ Determine absolute patency of vein; use of an IV catheter is preferred because severe cellulitis and tissue necrosis will result from extravasation. If extravasation occurs, discontinue injection and use another vein. Elevate extremity and apply cold compresses to extravasated area. Delayed erythema with or without ulceration has occurred at or distant to the injection site. May occur weeks to months after mitomycin administration, even when no obvious evidence of extravasation was observed during administration. ■ May precipitate acute respiratory distress syndrome. Oxygen can be toxic to the lungs; monitor intake carefully and use only enough to provide adequate arterial saturation. ■ Monitor fluid balance; avoid overhydration. ■ Be alert for signs of bone marrow suppression or infection. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Effective birth control recommended. ■ Report shortness of breath and IV site burning and stinging promptly. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy; may produce teratogenic effects on the fetus. ■ Information on safety in breast-feeding or in pediatric patients not available; discontinue breast-feeding.

Elderly:

Consider diminished hepatic function; monitor for early signs of toxicity.

DRUG/LAB INTERACTIONS

Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ May cause shortness of breath, severe bronchospasm, and acute pneumonitis with **vinca alkaloids** (e.g., vinblastine).

SIDE EFFECTS

Alopecia, anaphylaxis, anorexia, bleeding, blurring of vision, cellulitis at injection site, confusion, CHF (patient has usually received doxorubicin [Adriamycin, Doxil]), coughing, diarrhea, drowsiness, dyspnea with nonproductive cough, edema, elevated BUN or SCr, fatigue, fever, headache, hematemesis, hemolytic uremic syndrome (microangiopathic hemolytic anemia [hematocrit less than 25%], irreversible renal failure [SCr greater than 1.6 mg/dL], and thrombocytopenia [less than 100,000/mm^3]), hemoptysis, hypertension, leukopenia, mouth ulcers, nausea, paresthesias, pneumonia, pruritus, pulmonary edema, purple discoloration of vein, radiographic evidence of pulmonary infiltrates, rash, renal failure, respiratory distress syndrome (acute), skin toxicity, stomatitis, syncope, thrombocytopenia, thrombophlebitis, vomiting.

ANTIDOTE

Most side effects will be treated symptomatically. Keep the physician informed. All are potentially serious and many can be life threatening. Hematopoietic depression requires cessation of therapy until recovery occurs. Discontinue drug if dyspnea, nonproductive cough, or radiographic evidence of pulmonary infiltrates is present. Discontinue drug for any symptoms of hemolytic uremic syndrome. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrasti, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity; see Precautions. If extravasation has occurred, L.A. dexamethasone injected into the indurated area with a fine hypodermic needle may be helpful; elevate extremity.

MITOXANTRONE HYDROCHLORIDE **BBW**

(my-toe-**ZAN**-trohn hy-droh-**KLOR**-eyed)
Novantrone
Antineoplastic (antibiotic)
pH 3 to 4.5

USUAL DOSE

Pretreatment:

Preliminary evaluations and testing required; see Monitor. Verify pregnancy status; see Maternal/Child.

Combination initial therapy for acute nonlymphocytic leukemia (ANLL) in adults:

Induction: 12 mg/M^2/day of mitoxantrone on Days 1 through 3 and cytarabine 100 mg/M^2/day as a continuous 24-hour infusion on Days 1 through 7. Should a complete remission not be achieved, repeat mitoxantrone, 12 mg/M^2/day for only 2 days, and cytarabine 100 mg/M^2/day for 5 days after all signs or symptoms of severe or life-threatening nonhematologic toxicity have cleared.

Consolidation:

After full hematologic recovery (usually 6 weeks after induction therapy), administer mitoxantrone 12 mg/M^2/day by IV infusion on Days 1 and 2 and cytarabine 100 mg/M^2/day as a continuous 24-hour infusion on Days 1 to 5. May repeat in 4 weeks. Severe myelosuppression occurred in these subsequent courses. See Monitor.

Prostate cancer:

12 to 14 mg/M^2 as a short IV infusion once every 21 days. Used concurrently with steroids.

Multiple sclerosis (MS):

12 mg/M^2 as an infusion over 5 to 15 minutes. Repeat every 3 months. May be given for up to 2 years or until a cumulative dose of 140 mg/M^2 has been administered.

DOSE ADJUSTMENTS

Adjust dose based on clinical response and development and severity of toxicity. ■ Clearance is reduced by impaired hepatic function. Treat patients with impaired hepatic function with caution; dose adjustment may be indicated. Specific recommendations not available; see Precautions.

DILUTION

Specific techniques required; see Precautions.

A single dose must be diluted with at least 50 mL of NS or D5W. May be further diluted in NS, D5W, or D5NS. Must be given through Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS, or may be diluted in larger amounts of the same solutions and given as a continuous infusion.

Filters:

No data available from manufacturer.

Storage:

Store unopened vial at RT (15° to 25° C [59° to 77° F]). Do not freeze. Diluted solution should be used immediately. After penetration of the stopper on a multidose vial, the undiluted mitoxantrone may be stored at RT for 7 days or refrigerated for up to 14 days. Do not freeze.

COMPATIBILITY

Manufacturer recommends not mixing in the same infusion with other drugs until **compatibility** data are available and states that it may form a precipitate if mixed in the same infusion with heparin.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

A single dose of properly diluted medication over at least 3 to 5 minutes. Must be given through Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS.

Intermittent infusion:

A single dose over 15 to 30 minutes.

Infusion:

Sometimes a single dose is given as a continuous infusion over 24 hours. Is combined with cytarabine.

ACTIONS

An anthracenedione, a synthetic antibiotic antineoplastic agent. Has achieved complete remissions with a single course of combination therapy. Has a cytocidal effect on proliferating and nonproliferating cells. Probably not cell-cycle specific. Inhibits DNA and RNA synthesis. Thought to reduce the number of relapses and slow down progression of MS through its ability to suppress the activity of T-cells, B-cells, and macrophages. These cells attack the myelin sheath around nerve cells, causing the symptoms of MS. Improves the presentation of brain lesions on MRI studies. Extensive distribution to tissue occurs rapidly. Partially metabolized. Exact pathways unknown. Half-life varies from 23 to 213 hours (median 75 hours). Slowly excreted in bile, urine, and feces as either unchanged drug or as inactive metabolites.

INDICATIONS AND USES

Treatment of acute nonlymphocytic leukemia in adults; includes erythroid, monocytic, myelogenous, and promyelocytic acute leukemias. Given in combination with other approved drugs. ■ Treatment of bone pain in patients with advanced prostate cancer resistant to hormones. Used concurrently with steroids. ■ To reduce neurologic disability and/or the frequency of clinical relapses in patients with secondary (chronic) progressive, progressive relapsing, or worsening relapsing-remitting multiple sclerosis (i.e., patients whose neurologic status is significantly abnormal between relapses). Not indicated in the treatment of patients with primary progressive MS.

Unlabeled uses:

Treatment of acute lymphocytic leukemia (ALL), breast cancer, Hodgkin lymphoma, non-Hodgkin lymphomas, myelodysplastic syndrome, pediatric acute leukemias, pediatric sarcoma, and part of a conditioning regimen for autologous hematopoietic stem cell transplantation (HSCT).

CONTRAINDICATIONS

Hypersensitivity to mitoxantrone or other anthracyclines. ■ Not for intrathecal use; severe injury with permanent sequelae can result.

PRECAUTIONS

For IV use only. Do not administer SC, IM, intra-arterially, or intrathecally. ■ Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Use of goggles, gloves, and protective gown recommended. Flush skin copiously with warm water should any contact occur. Irrigate eyes immediately in case of contact. Clean spills with 5.5 parts calcium hypochlorite to 13 parts by weight of water for each 1 part of mitoxantrone. ■ Usually administered by or under the direction of the physician specialist with facilities for monitoring the patient and responding to any medical emergency. ■ Will cause severe myelosuppression; use extreme caution in pre-existing drug-induced bone marrow suppression. ■ Should not be given to patients with baseline neutrophil counts of less than 1,500 cells/mm^3 (except for the treatment of acute nonlymphocytic leukemia). ■ MS patients with a baseline left ventricular ejection fraction (LVEF) below the lower limit of normal or patients who have received a cumulative dose equal to or greater than 140 mg/M^2 should not be treated with mitoxantrone. ■ May cause severe cardiac toxicity (e.g., acute congestive heart failure) in all patients, even if cardiac risk factors are not present. May occur early during therapy or months to years after completion. Risk increased with cumulative doses (equal to or greater than 140 mg/M^2), in patients with pre-existing heart disease, and in patients previously treated with anthracyclines (see Drug/Lab Interactions), other cardiotoxic drugs, or radiation therapy encompassing the heart. ■ Use caution in impaired liver function. Clearance is decreased; see Dose Adjustments. Patients with MS who have hepatic impairment should ordinarily not be treated with mitoxantrone. ■ Use caution if renal function is impaired; has not been studied. ■ Urine and sclera may turn bluish in color. ■ Therapy with mitoxantrone increases the risk of developing secondary leukemia in patients with multiple sclerosis and in patients with cancer. Most commonly reported types are acute promyelocytic leukemia and acute myelocytic leukemia. The occurrence is more common when mitoxantrone is given in combination with other cytotoxic agents and/or radiotherapy or when doses of anthracyclines (e.g., doxorubicin, idarubicin) have been escalated. ■ Rapid lysis of cancer cells may cause tumor lysis syndrome. ■ See Monitor.

Monitor:

Obtain baseline CBC with differential and platelet count; repeat before each dose and if S/S of infection occur. ■ Complete a physical exam and ECG and obtain a complete history to assess for S/S of pre-existing cardiac disease. ■ In all patients, obtain an evaluation of left ventricular ejection fraction (LVEF) by echocardiogram or MUGA (multiple-gated acquisition) before therapy begins. ■ Evaluation of LVEF and assessment of cardiotoxicity by history, physical exam, and ECG should be repeated before each dose in MS patients. ■ Obtain repeat LVEF as indicated in all patients. ■ Mitoxantrone should not ordinarily be administered to MS patients who have received a cumulative dose equal to or greater than 140 mg/M^2 or to patients who experience a drop in LVEF to below the lower limit of normal or a clinically significant reduction in LVEF. MS patients should have an annual quantitative evaluation of LVEF after discontinuing mitoxantrone therapy to monitor for late-occurring cardiotoxicity. ■ Monitoring of liver function is indicated before and during therapy. ■ Because of rapid lysis of cancer cells, initiate hypouricemic therapy with allopurinol or similar agents before beginning treatment. Monitor uric acid levels, maintain hydration, and uric acid–lowering drugs (e.g., allopurinol) may be indicated. ■ Observe closely and frequently for all signs of bleeding or infection. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Determine absolute patency of vein. Severe local tissue damage may occur with extravasation. Phlebitis at the infusion site has also been reported. Should extravasation or phlebitis occur, discontinue injection and use another vein. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for S/S of acute leukemia (secondary leukemia); may include excessive bruising, bleeding, and recurrent infections. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Effective birth control recommended; see Maternal/Child. ■ Blood and cardiac tests are imperative; keep all appointments. ■ Report IV site burning or stinging promptly. ■ Urine may turn blue-green for 24 hours following administration. Bluish discoloration of sclera may also occur. ■ Medication guide available; read before beginning treatment with mitoxantrone. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: avoid pregnancy. May produce teratogenic effects on the fetus. Women with MS who are biologically capable of becoming pregnant should have a pregnancy test before each dose of mitoxantrone regardless of other methods of birth control used, including birth control pills. ■ Secreted in breast milk. Discontinue breast-feeding. ■ Safety for use in pediatric patients not established.

Elderly:

Specific age-related differences have not been identified; consider age-related organ impairment (e.g., bone marrow reserve, renal, hepatic) and possibility of increased sensitivity.

DRUG/LAB INTERACTIONS

Additive bone marrow suppression may occur with **radiation therapy and/or other bone marrow–suppressing agents** (e.g., azathioprine, chloramphenicol, melphalan). Dose reduction may be required. ■ Risk of cardiotoxicity increased in patients previously treated with maximum cumulative doses of **other anthracyclines** (e.g., doxorubicin, epirubicin, idarubicin) **and/or radiation encompassing the heart.** ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs.

SIDE EFFECTS

Alopecia (reversible), bladder infections, menstrual disorders, mucositis, and nausea occur frequently. Other side effects include abdominal pain, acute congestive heart failure, altered electrolytes, altered liver function tests (e.g., increased ALT, AST, BUN), arrhythmias, arthralgias, bleeding, bone marrow suppression (severe with standard doses), cardiotoxicity, conjunctivitis, cough, decrease in LVEF, diarrhea, dyspnea, erythema, fever, GI bleeding, headache, hematuria, hypersensitivity reactions (e.g., dyspnea, hypotension, rash, urticaria), infections, injection site burning, jaundice, leukemia (including secondary AML), mucositis, myalgias, nail bed changes, phlebitis, renal failure, seizures, skin discoloration, stomatitis, swelling, vomiting. Interstitial pneumonitis has been reported. Anaphylaxis has been reported rarely.

Post-Marketing:

Secondary acute myelogenous leukemia (AML).

ANTIDOTE

There is no specific antidote. Notify physician of all side effects. Most will be treated symptomatically. Blood and blood products, antibiotics, and other adjunctive therapies must be available. Blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Nadir of leukocyte count occurs within 10 days. Recovery is within 21 days. For extravasation, elevate extremity and apply ice. Monitor closely and obtain surgical consult if necessary. Overdose has resulted in death. Peritoneal dialysis or hemodialysis not effective. Supportive therapy as indicated will help sustain the patient in toxicity.

MOGAMULIZUMAB-kpkc

(moe-**GAM**-ue-**LIZ**-ue-mab-kpkc)
Poteligeo
Antineoplastic
Monoclonal antibody
pH 5.5

USUAL DOSE

Pretreatment:

Verify pregnancy status.

Premedication:

Premedicate with diphenhydramine and acetaminophen for the first mogamulizumab-kpkc infusion.

Mogamulizumab-kpkc:

1mg/kg administered as an IV infusion on Days 1, 8, 15, and 22 of the first 28-day cycle, then on Days 1 and 15 of each subsequent 28-day cycle until disease progression or unacceptable toxicity. Administer mogamulizumab-kpkc within 2 days of the scheduled dose. If a dose is missed, administer the next dose as soon as possible and resume dosing schedule.

DOSE ADJUSTMENTS

Permanently discontinue for life-threatening (Grade 4) rash or for Stevens-Johnson syndrome (SJS) or toxic epidermal necrolysis (TEN). If SJS or TEN is suspected, stop mogamulizumab-kpkc and do not continue unless SJS or TEN has been excluded and the cutaneous reaction has resolved to Grade 1 or less. ■ Interrupt mogamulizumab-kpkc and administer at least 2 weeks of topical corticosteroids if moderate or severe (Grade 2 or 3) rash occurs. If rash improves to Grade 1 or less, treatment may be resumed. ■ Temporarily interrupt infusion of mogamulizumab-kpkc for mild to severe (Grade 1 to 3) infusion reactions and treat symptoms. Reduce infusion rate by at least 50% when restarting infusion after symptoms resolve. Permanently discontinue mogamulizumab-kpkc for a life-threatening (Grade 4) infusion reaction. ■ See Antidote. ■ No clinically significant differences in the pharmacokinetics of mogamulizumab-kpkc were observed based on age, sex, race, renal impairment, or mild or moderate hepatic impairment. The effect of severe hepatic impairment (total bilirubin greater than 3 times the ULN and any AST) is unknown.

DILUTION

Available in a 20 mg/5 mL (4 mg/mL) clear to slightly opalescent, colorless solution in a single-dose vial. Calculate the dose (mg/kg) and number of vials needed to prepare the infusion based on patient’s weight. Aseptically withdraw the required volume of mogamulizumab-kpkc into the syringe and transfer into an IV bag containing NS. The final concentration of the diluted solution should be between 0.1 mg/mL and 3 mg/mL. Mix diluted solution by gentle inversion. ***Do not shake***.

Filters:

Infuse through a sterile, low–protein-binding, 0.22-micron (or equivalent) in-line filter.

Storage:

Store vials in refrigerator at 2° to 8° C (36° to 46° F). Keep in original package to protect from light. ***Do not freeze or shake vials or diluted solution.*** Diluted solution should be infused immediately or stored under refrigeration at 2° to 8° C (36° to 46° F) no more than 4 hours from the time of infusion preparation. Discard any unused portion left in the vial.

COMPATIBILITY

Manufacturer states, "Do not coadminister other drugs through the same intravenous line."

Do not mix mogamulizumab-kpkc with other drugs. The diluted solution is **compatible** with polyvinyl chloride (PVC) and polyolefin (PO) infusion bags.

RATE OF ADMINISTRATION

Administer as an IV infusion over at least 60 minutes. Do not administer by rapid IV administration. Infuse through a sterile, low–protein-binding, 0.22-micron (or equivalent) in-line filter.

ACTIONS

Mogamulizumab-kpkc is a defucosylated, humanized, IgG1 kappa monoclonal antibody that binds to CC chemokine receptor 4 (CCR4), a G protein–coupled receptor for CC chemokines that is involved in the trafficking of lymphocytes to various organs. CCR4 is expressed on the surface of some T-cell malignancies (e.g., mycosis fungoides, Sézary syndrome) and is expressed on regulatory T-cells (Tregs) and a subset of Th2 T-cells. Nonclinical in vitro studies demonstrate that mogamulizumab-kpkc binding to CCR4 targets a cell for antibody-dependent cellular cytotoxicity, resulting in depletion of the target cells. The terminal half-life is 17 days.

INDICATIONS AND USES

Treatment of adult patients with relapsed or refractory mycosis fungoides (MF) or Sézary syndrome (SS) after at least one prior systemic therapy.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Do not administer subcutaneously or by rapid IV administration. ■ Fatal and life-threatening skin reactions, including SJS and TEN, have occurred. The onset of drug eruption is variable, and the affected areas and appearance can vary. ■ Fatal and life-threatening infusion reactions have occurred. Most reactions occurred during or shortly after the first infusion but can also occur with subsequent infusions. ■ Fatal and life-threatening infections have occurred, including pneumonia, skin infection, and sepsis. ■ Fatal and life-threatening immune-mediated complications have been reported, including hepatitis, myositis, myocarditis, new-onset hypothyroidism, pneumonitis, polymyositis, and a variant of Guillain-Barré syndrome. ■ Increased risk of transplant complications have been reported in patients who receive allogeneic HSCT after mogamulizumab-kpkc, including severe (Grade 3 or 4) acute graft-versus-host disease (GVHD), steroid-refractory GVHD, and transplant-related death. A higher risk of transplant complications has been reported if mogamulizumab-kpkc is given within a shorter time frame (approximately 50 days) before HSCT. ■ As with all therapeutic proteins, there is a potential for immunogenicity.

Monitor:

Monitor for rash throughout course of treatment. Consider skin biopsy to help distinguish drug eruption from disease progression. ■ Monitor for S/S of infusion reactions (e.g., chills, fever, headache, nausea, rigors, tachycardia, and vomiting). Interrupt the infusion for any grade reaction and treat promptly. Consider premedication (e.g., diphenhydramine, acetaminophen) with subsequent infusions. ■ Monitor for S/S of infection (e.g., chills, cough, diarrhea or stomach pain, fever) and treat promptly. ■ Monitor for immune-mediated complications. Consider the benefit/risk of treatment in patients with a history of autoimmune disease. ■ Follow patients who have received allogeneic HSCT after mogamulizumab-kpkc closely for early evidence of transplant-related complications. ■ See Dose Adjustments. ■ See Antidote.

Patient Education:

Read FDA-approved patient information. ■ Tell your health care provider about all past or present medical conditions, including any history of autoimmune disease. ■ Immediately report new or worsening skin rash and S/S of infusion reaction (e.g., coughing, chills, dizziness, itching, wheezing). ■ Contact your health care provider for fever or other evidence of infection (e.g., cough, chills, fever, flu-like symptoms). ■ Females of reproductive potential should use effective contraception during treatment and for at least 3 months after the last dose. ■ There is a potential risk for posttransplant complications in patients who receive allogeneic HSCT after mogamulizumab-kpkc.

Maternal/Child:

Not recommended during pregnancy or in women of childbearing potential who are not using contraception. ■ Safety for use during breast-feeding not established; effects unknown. Consider risk versus benefit. ■ Safety and effectiveness for use in pediatric patients have not been established.

Elderly:

No overall differences in effectiveness have been observed between elderly patients and younger patients. A higher incidence of serious adverse reactions was seen in patients 65 years of age or older.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted.

SIDE EFFECTS

The most common side effects (≥20% of patients) were diarrhea, fatigue, infusion-related reactions, musculoskeletal pain, rash, and upper respiratory tract infection. Serious side effects reported include autoimmune complications, complications of allogeneic HSCT, dermatologic toxicity, infections, and infusion reactions; see Precautions. Laboratory abnormalities include decreased albumin, glucose, magnesium, and phosphate; decreased or increased calcium; increased uric acid; and decreased CD4 lymphocytes, lymphocytes, and WBCs. Other side effects include abdominal pain, alopecia, anemia, arrhythmia, candidiasis, cardiac failure, chills, conjunctivitis, constipation, cough, decreased appetite, depression, dizziness, dyspnea, edema, fall, fever, folliculitis, headache, hepatitis, herpesvirus infection, hyperglycemia, hypertension, hyperuricemia, hypomagnesemia, insomnia, lower respiratory tract infection, mucositis, muscle spasms, myocardial ischemia or infarction, nausea, otitis, peripheral neuropathy, pneumonia, pneumonitis, renal insufficiency, sepsis, skin infection, thrombocytopenia, tumor lysis syndrome, urinary tract infection, vomiting, weight decrease/increase, and xerosis. Other side effects have occurred.

Post-Marketing:

Hepatitis B virus reactivation and stress cardiomyopathy.

ANTIDOTE

Keep physician informed of all side effects. If mild (Grade 1) rash occurs, consider topical corticosteroids. Permanently discontinue for life-threatening (Grade 4) rash or for Stevens-Johnson syndrome (SJS) or toxic epidermal necrolysis (TEN). Management of dermatologic toxicity includes topical corticosteroids and interruption or permanent cessation of treatment; see Dose Adjustments. If an infusion reaction occurs, consider premedication with diphenhydramine and acetaminophen for subsequent infusions. Permanently discontinue for life-threatening (Grade 4) infusion reactions. Temporarily interrupt infusion for mild to severe (Grade 1 to 3) infusion reactions and treat symptomatically. Reduce infusion rate by at least 50% when restarting infusion after symptoms resolve. If reaction recurs and is unmanageable, discontinue infusion; see Dose Adjustments. Interrupt or permanently discontinue treatment as appropriate for suspected immune-mediated reactions. Treat reactions as indicated.

MORPHINE SULFATE BBW

(**MOR**-feen **SUL**-fayt)
Astramorph PF, Duramorph PF
Opioid analgesic (agonist)
Adjunct, pulmonary edema
Anesthesia adjunct
pH 2.5 to 6.5

USUAL DOSE

Individualize dose, taking into account the patient’s severity of pain, patient response, prior analgesic treatment experience, and risk factors for addiction, abuse, and misuse. Use lowest effective dose for the shortest duration consistent with the patient’s treatment goals.

IV injection:

One manufacturer recommends an initial dose of 2 to 10 mg/70 kg of body weight. Repeat every 3 to 4 hours as necessary. Another manufacturer recommends a starting dose of 0.1 to 0.2 mg/kg every 4 hours as needed. Titrate to the lowest possible dose that provides adequate analgesia and minimizes adverse reactions. Administration of smaller, more frequent doses (e.g., 2 to 3 mg every 5 minutes) may be an appropriate way to achieve pain control and/or manage the development of adverse events (e.g., sedation, decreased oxygen saturation) when treating acute moderate to severe pain in a closely monitored setting such as the emergency department or the postanesthesia care unit. When this is done, orders should contain a maximum cumulative dose to trigger reassessment of pain and continued therapy.

Acute MI (unlabeled):

4 to 8 mg initially. May give additional doses of 2 to 8 mg at 5- to 15-minute intervals as needed (AHA guidelines).

Infusion (unlabeled):

Used postoperatively with a patient-controlled analgesic device (PCA) and/or as a continuous infusion in select terminally ill cancer patients. ***Continuous Infusion (opioid tolerant):*** 0.8 to 10 mg/hr. Higher doses have been used. A continuous infusion is not recommended in opioid-naïve patients. ***PCA infusion:*** One source suggests a concentration of 1 mg/mL, with a starting patient-controlled dose of 1 mg (range: 0.5 to 2.5 mg) that can be activated at prescribed intervals (e.g., every 5 to 10 minutes). Must be administered through a controlled infusion device that may be patient activated. The initial loading dose, the continuous background infusion (if prescribed), additional patient-activated doses with a specific time interval, additional health care professional–provided boluses with a specific time interval, and the total dose allowed per hour must be determined by the physician and individualized for each patient. In select cancer or chronic pain patients, these doses may be considerably higher.

Dyspnea during end-of-life care (unlabeled):

2 to 5 mg IV every 2 to 4 hours as needed.

PEDIATRIC DOSE

Analgesic:

Usual range is 0.05 to 0.1 mg/kg. Administer very slowly.

Postoperative analgesia:

0.01 to 0.04 mg/kg/hr (10 to 40 mcg/kg/hr).

Select pediatric patients with severe chronic cancer pain or during sickle cell crisis:

0.025 to 2.6 mg/kg/hr (average 0.04 to 0.07 mg/kg/hr).

NEONATAL DOSE

Elimination is reduced in neonates, and they have an increased susceptibility to CNS side effects.

Analgesia/tetralogy (cyanotic) spells (unlabeled):

0.05 to 0.2 mg/kg/dose every 4 hours. Titrate to individual response. Another source suggests an ***IV injection*** of 0.05 to 0.1 mg/kg/dose every 4 to 8 hours or an ***IV infusion*** of 0.01 to 0.02 mg/kg/hr. Titrate to individual response.

DOSE ADJUSTMENTS

Reduced dose and/or extended intervals may be required in impaired renal or hepatic function and in elderly, cachectic, or debilitated patients. ■ Doses appropriate for the general population may cause serious respiratory depression in vulnerable patients. ■ Increase doses as required if analgesia is inadequate, tolerance develops, or pain severity increases. The first sign of tolerance is usually a reduced duration of effect. ■ Higher doses may be required in patients with chronic pain. ■ See Drug/Lab Interactions.

DILUTION

Morphine is available in several concentrations for direct injection, infusion, and PCA use. Dosing errors can result in accidental overdose and death. Avoid dosing errors that may result from confusion between mg and mL and confusion with morphine products of different concentrations when prescribing, dispensing, and administering morphine.

IV injection:

May be given undiluted. May be given through Y-tube or three-way stopcock of infusion set.

Infusion:

Each 0.1 to 1 mg is usually diluted in 1 mL NS or D5W and administered via a controlled infusion device. Infusion may be administered at a set rate or may be administered using a patient-controlled analgesia (PCA) system. Higher concentrations may be used in opioid-tolerant patients or for end-of-life infusions. Products for infusion are available in multiple sizes and concentrations. Some products are manufactured for specific infusion devices (i.e., are **compatible** with one brand of infusion device). (***Astramorph PF and Duramorph*** are preservative-free and expensive; can be used IV, but are the only choice for epidural or intrathecal injection; see drug literature. ***Duramorph*** is **NOT** for use in continuous microinfusion devices. ***Infumorph*** is **NOT** for IV use.) Fluid restriction or high doses may require more concentrated solutions.

Storage:

Store at CRT. Protect from light and freezing.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Frequently titrated according to symptom relief and respiratory rate. Side effects markedly increased if rate of injection is too rapid. Because of a delay in maximum CNS effect with an intravenously administered drug (30 minutes), rapid IV administration may result in overdosing. Rapid IV administration may result in chest wall rigidity.

IV injection:

A single dose over 4 to 5 minutes.

Infusion:

All parameters (outlined in Usual Dose) should be ordered by the physician. Any dose requiring a controlled infusion device requires accurate titration and close monitoring.

ACTIONS

A mu-opioid receptor agonist. Precise mode of action is unknown, but opioids are believed to combine with specific CNS opiate receptors. Produces a wide spectrum of pharmacologic effects, including analgesia, diminished GI mobility, dysphoria, euphoria, peripheral vasodilation, respiratory depression, and somnolence. Relieves pulmonary congestion, lowers myocardial oxygen requirements, and reduces anxiety. The principal therapeutic action of morphine is analgesia. Pain relief is effected almost immediately. Metabolized in the liver. Excreted in the urine and to a lesser extent in feces. Elimination half-life is 1.5 to 2 hours (range: 1.5 to 4 hours). Crosses the blood-brain barrier, but plasma concentration is higher than CSF concentration. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Management of pain severe enough to require an opioid analgesic and for which alternative treatments are inadequate.

Unlabeled uses:

Pain associated with MI, acute pulmonary edema, and analgesia in critically ill patients. Treatment of dyspnea in end-of-life care. ■ Control of postoperative pain in neonates.

Limitations of use:

Because of the risk of addiction, abuse, and misuse, even at recommended doses, reserve morphine for use in patients for whom alternative treatment options (e.g., nonopioid analgesics or opioid combination products):

- Have not been tolerated or are not expected to be tolerated
- Have not provided adequate analgesia or are not expected to provide adequate analgesia

CONTRAINDICATIONS

Hypersensitivity to morphine sulfate or any component of the formulation. ■ Significant respiratory depression. ■ Acute or severe bronchial asthma in the absence of resuscitation equipment or in unmonitored settings. ■ In patients with, known, or suspected to have GI obstruction, including paralytic ileus. ■ Concurrent use of monoamine oxidase inhibitors (MAOIs) within the last 14 days. ■ Specific formulations may have additional contraindications; see prescribing information. ■ ***Duramorph*** is **NOT** for use in continuous microinfusion devices.

PRECAUTIONS

Morphine exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient’s risk before prescribing morphine, and monitor all patients regularly for the development of these behaviors and conditions. Strategies to reduce the risk of diversion or misuse should be used by health care facilities that use this and other controlled substances. ■ See prescribing information for further discussion regarding abuse, addiction, physical dependence, and tolerance. ■ Serious, life-threatening, or fatal respiratory depression may occur with the use of morphine. Because of a delay in maximum CNS effect with an intravenously administered drug (30 minutes), rapid IV administration may result in overdosing. Adequate facilities should be available for monitoring and ventilation. An opioid antagonist (e.g., naloxone), resuscitative and intubation equipment, and oxygen should be readily available. ■ Although low doses of IV morphine have little effect on cardiovascular stability, high doses are excitatory and result from sympathetic hyperactivity and an increase in circulatory catecholamines. Use caution in patients with atrial flutter and other supraventricular tachycardias because of a possible vagolytic action that may produce a significant increase in ventricular response rate. ■ Use with extreme caution in patients with COPD, cor pulmonale, a substantially decreased respiratory reserve, hypoxia, hypercapnia, or pre-existing respiratory depression; these patients are at increased risk for decreased respiratory drive, including apnea, even at recommended doses. Consider using nonopioid analgesics, or administer under careful medical supervision at the lowest effective dose. ■ Use with caution and reduce initial doses in elderly, cachectic, or debilitated patients and in patients with severe impairment of hepatic, pulmonary, or renal function. Consider using nonopioid analgesics. ■ Cases of serotonin syndrome have been reported during concomitant use of morphine with serotonergic drugs. ■ Cases of adrenal insufficiency have been reported with opioid use, more often after more than 1 month of use. If adrenal insufficiency is diagnosed, treat with physiologic replacement doses of corticosteroids and wean the patient off the opioid to allow adrenal function to recover. Another opioid may be tried, because some cases reported use of a different opioid without recurrence of adrenal insufficiency. ■ May cause severe hypotension, including orthostatic hypotension and syncope, in ambulatory patients or in any patient whose ability to maintain blood pressure has been compromised by depleted blood volume or concomitant administration of drugs that can cause hypotension (e.g., anesthetics, phenothiazines); see Drug/Lab Interactions. In patients with circulatory shock, morphine-induced vasodilation may further reduce cardiac output and blood pressure. Use should be avoided. ■ Use caution in patients with head injury, brain tumors, or increased intracranial pressure. Respiratory depression may cause an increased P_{CO_2}, cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. Avoid use in patients with impaired consciousness or coma. ■ Use with caution in patients with biliary tract disease, including acute pancreatitis; may cause spasm of the sphincter of Oddi and diminish biliary and pancreatic secretions. ■ May increase the frequency of seizures in patients with a convulsive disorder and may induce or aggravate seizures in some clinical settings. ■ Do not abruptly discontinue morphine in a patient who is physically dependent; dose must be tapered gradually.

Monitor:

Monitor for respiratory depression, especially during initiation of therapy (within the first 24 to 72 hours) or after a dose increase. Oxygen, naloxone, and equipment to establish and maintain an airway must be available. ■ Assess baseline pain, reassess after administration of morphine, and adjust dose or interval as required. ■ Monitor vital signs and oxygenation and observe patient frequently. ■ Keep patient supine; orthostatic hypotension and fainting may occur; less likely with continuous low doses, but observe closely during ambulation. ■ Monitor patients who may be susceptible to the intracranial effects of CO_2 retention for increasing intracranial pressure and signs of sedation and respiratory depression. ■ Monitor patients with biliary tract disease for worsening of symptoms. ■ Monitor patients with a history of seizure disorders for worsening seizure control. ■ Monitor for S/S of serotonin syndrome (e.g., mental status changes [e.g., agitation, coma, hallucinations], autonomic instability [e.g., hyperthermia, labile blood pressure, tachycardia], neuromuscular aberrations [e.g., hyperreflexia, incoordination, rigidity], and/or GI symptoms [e.g., diarrhea, nausea, vomiting]). Onset of symptoms may occur within hours to days of concomitant use of opioids with serotonergic drugs. ■ Uncontrolled pain causes sleep deprivation, decreases pain threshold, and increases pain. When pain is finally controlled, expect the patient to sleep more until recovery from sleep deprivation. ■ Adhere to prescribed bowel care regimen to avoid constipation and/or impaction. Maintain adequate hydration. ■ See Drug/Lab Interactions.

Patient Education:

Avoid alcohol or other CNS depressants (e.g., barbiturates, benzodiazepines [e.g., diazepam]). Review all medications for interactions. ■ May cause blurred vision, dizziness, or drowsiness; use caution in tasks that require alertness. ■ Request assistance with ambulation. ■ Promptly report unrelieved pain or unacceptable side effects. ■ Promptly report S/S of serotonin syndrome. ■ May result in severe constipation. Scheduled bowel regimen recommended. ■ May result in addiction, abuse, and misuse, even when taken as recommended.

Maternal/Child:

Use during pregnancy only if the potential benefit justifies the risk to the fetus. ■ Use during labor and delivery may produce respiratory depression and a physiologic effect in neonates. Closely monitor neonates exposed to morphine during labor and delivery for signs of excessive sedation and respiratory depression. May also prolong labor by reducing the strength, duration, and frequency of contractions. ■ Prolonged use of morphine during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life threatening if not recognized and treated. Infants born to mothers receiving morphine during pregnancy should be monitored closely and treated for neonatal opioid withdrawal syndrome, if indicated. See literature for treatment protocols. Infants born to mothers physically dependent on opioids will also be physically dependent and may exhibit respiratory difficulties and withdrawal symptoms (e.g., excessive crying, fever, hyperactive reflexes, increased respiratory rate, increased stools, sneezing, tremors, vomiting, yawning). ■ Use caution with breast-feeding. Monitor infants exposed to morphine through breast milk for excess sedation and respiratory depression. Withdrawal symptoms can occur in breast-fed infants when maternal administration of an opioid analgesic is stopped or when breast-feeding is stopped. ■ Safety and effectiveness for use in pediatric patients not established. ■ Pediatric patients may be more sensitive to effects, especially respiratory depressant effects.

Elderly:

See Dose Adjustments and Precautions. ■ May be more sensitive to effects (e.g., respiratory depression, constipation, urinary retention). Respiratory depression is the chief risk for elderly patients treated with opioids. ■ Lower doses may provide effective analgesia. ■ Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

Concomitant use of morphine with **benzodiazepines** and other **CNS depressants** may result in profound sedation, respiratory depression, coma, and death. Hypotension can also occur. Reserve concomitant use for patients for whom alternative treatment options are inadequate. Limit dose and duration of treatment to the minimum required, and monitor patients carefully for S/S of respiratory depression and sedation. ■ Serotonin syndrome has been reported with the concomitant use of opioids, including morphine, and other **drugs that affect the serotonergic neurotransmitter system** (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin and norepinephrine reuptake inhibitors [SNRIs], tricyclic antidepressants [TCAs], triptans, 5-HT3 receptor antagonists, mirtazapine, trazodone, tramadol, MAO inhibitors, and linezolid). Careful observation, particularly during treatment initiation and dose adjustment, is required with concomitant use. ■ Severe and unpredictable potentiation of **MAO inhibitors** (e.g., linezolid) has been reported. MAO inhibitor interactions may manifest as serotonin syndrome or opioid toxicity (e.g., respiratory depression, coma). Use of morphine is not recommended for patients taking MAOIs or within 14 days of stopping such treatment. If urgent use of an opioid is necessary, use test doses and frequent titration of small doses to treat pain while closely monitoring BP and S/S of CNS and respiratory depression. ■ **Mixed agonist/antagonist analgesics and partial agonists** may reduce the analgesic effect of morphine and/or precipitate withdrawal symptoms. Avoid concomitant use. ■ Morphine may enhance the neuromuscular blocking action of **skeletal muscle relaxants**, increasing the degree of respiratory depression. Monitor patient and decrease dose if indicated. ■ Opioids can reduce the efficacy of **diuretics** by inducing the release of antidiuretic hormone. Increase dose of diuretic if needed. ■ Concomitant use with **anticholinergic drugs** may increase the risk of urinary retention and/or severe constipation, which may lead to paralytic ileus. ■ Concomitant administration with **cimetidine** may precipitate apnea, confusion, and muscle twitching.

SIDE EFFECTS

The most frequently reported adverse reactions are constipation, diaphoresis, dizziness, light-headedness, nausea, sedation, and vomiting. Serious adverse reactions include respiratory depression and apnea and, to a lesser degree, circulatory depression, respiratory arrest, shock, and cardiac arrest. Anaphylactoid reactions have been reported rarely. Other reported adverse reactions include agitation, biliary tract spasm, bradycardia, depression of cough reflex, dysphoria, euphoria, faintness, headache, histamine-related reactions (e.g., local tissue irritation, pruritus, urticaria, wheals), hypersensitivity reactions, increased intracranial pressure, interference with thermal regulation, oliguria, orthostatic hypotension, palpitations, serotonin syndrome, syncope, tachycardia, transient hallucinations and disorientation, tremors, uncoordinated muscle movement, urinary retention, visual disturbances, and weakness.

Overdose:

Apnea, atypical snoring, bradycardia, cardiac arrest, circulatory depression or collapse, cold and clammy skin, constricted pupils, hypotension (severe), partial or complete airway obstruction, pulmonary edema, respiratory depression or arrest, skeletal muscle flaccidity, somnolence progressing to stupor or coma, and death.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. Naloxone will reverse cardiovascular, CNS, and respiratory reactions. Naloxone use should be reserved for situations in which clinically significant respiratory or circulatory depression is present. Titrate naloxone dose carefully to avoid precipitating an acute abstinence syndrome or uncontrolled pain. The duration of action of morphine may exceed the duration of action of naloxone. Monitor patient carefully. Repeat doses of naloxone may be required. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Resuscitate as necessary.

MOXIFLOXACIN HYDROCHLORIDE BBW

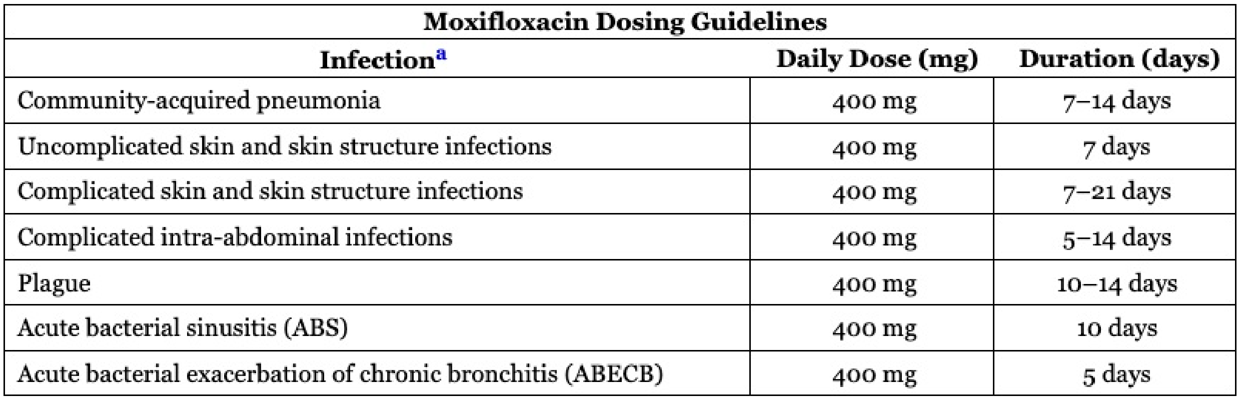
(mox-ee-**FLOX**-ah-sin hy-droh-**KLOR**-eyed)
Avelox
Antibacterial (fluoroquinolone)
pH 4.1 to 4.6

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor. See Maternal/Child.

400 mg once every 24 hours. Duration of therapy is based on diagnosis as listed in the following chart. Serum levels similar by oral or IV route. Transfer to oral therapy as soon as practical; no dose adjustment necessary. The magnitude of QT prolongation may increase with increasing serum concentrations. Do not exceed recommended dose.



Moxifloxacin Dosing Guidelines

Infection[a]	Daily Dose (mg)	Duration (days)
Community-acquired pneumonia	400 mg	7–14 days
Uncomplicated skin and skin structure infections	400 mg	7 days
Complicated skin and skin structure infections	400 mg	7–21 days
Complicated intra-abdominal infections	400 mg	5–14 days
Plague	400 mg	10–14 days
Acute bacterial sinusitis (ABS)	400 mg	10 days
Acute bacterial exacerbation of chronic bronchitis (ABECB)	400 mg	5 days

[a] Due to the designated pathogens.

DOSE ADJUSTMENTS

Dose adjustment is not indicated based on age, gender, or race; in impaired renal function (including patients on hemodialysis or CAPD); or in mild, moderate, or severe impaired hepatic function (Child-Pugh Classes A, B, and C). See Precautions.

DILUTION

Available in ready-to-use latex-free flexibags containing 400 mg moxifloxacin in 0.8% saline. No further dilution is necessary. Refer to directions provided with administration set.

Filters:

No data available from manufacturer.

Storage:

Store at CRT. Do not refrigerate; a precipitate will form. Discard unused portions.

COMPATIBILITY

Limited **compatibility** data available. Manufacturer states, “Other IV substances, additives, or other medications should not be added to moxifloxacin or infused simultaneously through the same IV line.” Flush line with a solution **compatible** to both drugs before and after administration of moxifloxacin and/or any other drug through the same IV line. May be administered through a Y-tube or three-way stopcock. Temporarily discontinue other solutions infusing at the same site.

Y-site:

Manufacturer lists as **compatible** with NS, D5W, D10W, SWFI, LR at ratios from 1:10 to 10:1.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Single dose equally distributed over 60 minutes as an infusion. Avoid rapid or bolus IV infusion. Incidence and magnitude of QT prolongation may increase with increasing concentrations or increasing rates of infusion. Do not exceed the recommended rate of infusion. Flush tubing before and after moxifloxacin with a **compatible** solution.

ACTIONS

A synthetic broad-spectrum fluoroquinolone antibacterial agent. Effective against a wide range of gram-negative and gram-positive organisms, including common respiratory pathogens such as *Streptococcus pneumoniae, Haemophilus influenzae,* and *Moraxella catarrhalis,* and atypicals such as *Chlamydophila pneumoniae* and *Mycoplasma pneumoniae*. Bactericidal action results from inhibition of topoisomerase II and IV, which are required for bacterial DNA replication, transcription, repair, and recombination. Mechanism of action of fluoroquinolones differs from that of aminoglycosides, cephalosporins, macrolides, beta-lactams, and tetracyclines, and fluoroquinolones may be active against pathogens resistant to these antibiotics. There is no cross-resistance between fluoroquinolones and these other antibiotics. Widely distributed throughout the body. Concentrations in most target tissues are higher than those found in plasma. Mean half-life is approximately 8.5 to 17 hours. Partially metabolized in the liver by glucuronide and sulfate conjugation. Excreted as unchanged drug and metabolites in feces and urine. May be secreted in breast milk.

INDICATIONS AND USES

Treatment of adults with infections caused by susceptible strains of designated microorganisms in conditions listed in this section. ■ Treatment of community-acquired pneumonia caused by many organisms, including *Streptococcus pneumoniae* (including multidrug-resistant strains [MDRSP]). MDRSP strains are resistant to two or more of the following antibiotics: penicillin, second-generation cephalosporins (e.g., cefuroxime), macrolides, tetracyclines, and sulfamethoxazole/trimethoprim. ■ Treatment of complicated and uncomplicated skin and skin structure infections. ■ Treatment of complicated intra-abdominal infections, including polymicrobial infections such as abscess. ■ Treatment of the plague, including pneumonic and septicemic plague, and prophylaxis of plague in adult patients. ■ Treatment of acute bacterial exacerbation of chronic bronchitis (ABECB) and acute bacterial sinusitis (ABS). Because fluoroquinolones, including moxifloxacin, have been associated with serious adverse reactions and because for some patients ABECB and ABS are self-limiting, reserve moxifloxacin for treatment in patients who have no alternative treatment options.

CONTRAINDICATIONS

History of hypersensitivity to moxifloxacin or other quinolone antibiotics (e.g., ciprofloxacin, levofloxacin, norfloxacin).

PRECAUTIONS

For IV use only. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, moxifloxacin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ C/S studies indicated to determine susceptibility of the causative organism to moxifloxacin. ■ Cross-resistance has been observed between moxifloxacin and other fluoroquinolones against gram-negative bacteria. However, gram-positive bacteria resistant to other fluoroquinolones may still be susceptible to moxifloxacin. ■ Observed emergence of bacterial resistance to fluoroquinolones and the occurrence of cross-resistance with other fluoroquinolones are of concern. Proper use of fluoroquinolones and other classes of antibiotics is encouraged to avoid the emergence of resistant bacteria from overuse. ■ Prolonged use may cause superinfection because of overgrowth of nonsusceptible organisms. ■ Fluoroquinolones, including moxifloxacin, have been associated with disabling and potentially irreversible serious adverse reactions that have occurred together in the same patient. Commonly seen adverse reactions include tendinitis and tendon rupture, arthralgia, myalgia, peripheral neuropathy, and CNS effects (e.g., anxiety, confusion, depression, hallucinations, insomnia, severe headaches). These reactions can occur within hours to weeks after starting moxifloxacin and have been seen in patients of any age and in patients without any pre-existing risk factors. Discontinue moxifloxacin immediately and avoid the use of fluoroquinolones, including moxifloxacin, in patients who experience any of these serious adverse reactions. ■ Prolongation of the QT interval on ECG and infrequent cases of arrhythmia (including torsades de pointes) have been reported. The risk of arrhythmia may be reduced by avoiding the use of moxifloxacin in patients with known prolongation of the QT interval, uncorrected electrolyte imbalances (e.g., hypokalemia, hypomagnesemia), significant bradycardia, cardiomyopathy, ventricular arrhythmias (including torsade de pointes), myocardial ischemia, or in patients being treated with Class Ia antiarrhythmic agents (e.g., quinidine, procainamide) or Class III antiarrhythmic agents (e.g., amiodarone, sotalol) or any other drug that can prolong the QT interval; see Drug/Lab Interactions. ■ Use caution in patients with mild, moderate, or severe hepatic insufficiency; associated metabolic disturbances may lead to QT prolongation. ■ Fluoroquinolones, including moxifloxacin, have been associated with an increased risk of seizures (convulsions), increased intracranial pressure (pseudo-tumor cerebri), tremors, and light-headedness. May trigger seizures or lower the seizure threshold. Use caution in patients with epilepsy or known or suspected CNS disorders that may predispose patients to seizures or lower the seizure threshold (e.g., severe cerebral arteriosclerosis, previous history of convulsions, reduced cerebral blood flow, altered brain structure, or stroke) or in the presence of other risk factors that may predispose patients to seizures (e.g., drugs that may lower the seizure threshold, renal dysfunction). ■ Fluoroquinolones, including moxifloxacin, have been associated with an increased risk of psychiatric adverse reactions, including toxic psychosis; psychotic reactions progressing to suicidal ideations/thoughts, hallucinations, or paranoia; depression, or self-injurious behavior such as attempted or completed suicide; anxiety, agitation, restlessness, or nervousness; confusion, delirium, disorientation, or disturbances in attention; insomnia or nightmares; and memory impairment. These reactions may occur after the first dose. ■ Tendinitis and tendon rupture that required surgical repair or resulted in prolonged disability have been reported in patients of all ages receiving quinolones. Most frequently involves the Achilles tendon but has also been reported with the shoulder, hand, biceps, thumb, and other tendon sites. ■ Tendinitis or tendon rupture may occur during or for up to months after fluoroquinolone therapy and may occur bilaterally. Risk may be increased in patients over 60 years of age; in patients taking corticosteroids; in patients with heart, kidney, or lung transplants; with strenuous physical activity; and in patients with renal failure or previous tendon disorders such as rheumatoid arthritis. Avoid moxifloxacin in patients who have a history of tendon disorders or have experienced tendinitis or tendon rupture. Discontinue moxifloxacin immediately if patient experiences pain, swelling, inflammation, or rupture of a tendon. ■ Fluoroquinolones have neuromuscular blocking activity and may exacerbate muscle weakness in persons with myasthenia gravis. Serious adverse events, including requirement for ventilatory support and deaths, have been reported in these patients. Avoid use in patients with a known history of myasthenia gravis. ■ Fluoroquinolones, including moxifloxacin, have been associated with an increased risk of peripheral neuropathy. Cases of sensory or sensorimotor axonal polyneuropathy resulting in paresthesias, hypoesthesias, dysesthesias (impairment of sensitivity or touch), or weakness have been reported. Symptoms may occur soon after initiation of therapy and may be irreversible. Avoid moxifloxacin in patients who have previously experienced peripheral neuropathy. ■ Serious and occasionally fatal hypersensitivity and/or anaphylactic reactions have been reported. Often occur after the first dose. ■ Other serious events (sometimes fatal) due to hypersensitivity or uncertain etiology have been reported with fluoroquinolones, including moxifloxacin. Usually occur following multiple doses. Manifestations may include things such as allergic pneumonitis, renal impairment/failure, hematologic toxicity, hepatic necrosis/failure, vasculitis, and dermatologic toxicity; see Side Effects, Post-Marketing. Discontinue moxifloxacin at the first appearance of a skin rash, jaundice, or other signs of hepatotoxicity or hypersensitivity. ■ Epidemiologic studies report an increased rate of aortic aneurysm and dissection within 2 months after use of fluoroquinolones, particularly in elderly patients. In patients with a known aortic aneurysm or in patients who are at greater risk for aortic aneurysms, moxifloxacin use should be limited to those cases in which no alternative antibacterial treatments are available. ■ Fluoroquinolones, including moxifloxacin, have been associated with disturbances of blood glucose, including symptomatic hyperglycemia and hypoglycemia, usually in patients with diabetes who are receiving concomitant treatment with an oral hypoglycemic agent (e.g., glyburide [DiaBeta]) or with insulin. In these patients, careful monitoring of blood glucose is recommended. Severe cases of hypoglycemia resulting in coma or death have been reported. ■ Moderate to severe photosensitivity/phototoxicity reactions have been reported in patients receiving quinolones; see Patient Education. ■ *Clostridium* *difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Due to the potential serious side effects, the FDA recommends not to use fluoroquinolones if other options are available. ■ See Monitor.

Monitor:

Obtain baseline and periodic CBC with differential and blood glucose. ■ Monitor for S/S of a hypersensitivity reaction (e.g., cardiovascular collapse, dyspnea, itching, loss of consciousness, pharyngeal or facial edema, tingling, urticaria). May be seen with first or subsequent doses. Emergency equipment must be readily available; see Side Effects. ■ Monitor for S/S of peripheral neuropathy. Discontinue moxifloxacin at first symptoms of neuropathy (e.g., pain, burning, tingling, numbness and/or weakness) or if patient has deficits in light touch, pain, temperature, position sense, vibratory sensation, and/or motor strength. ■ ECG monitoring for QT prolongation may be indicated in select patients. ■ Monitor for CNS adverse effects, including altered mental status, seizures, and changes in mood or behavior. ■ Monitor for S/S of tendinitis or tendon rupture. ■ Maintain adequate hydration to prevent concentrated urine throughout treatment. Other quinolones have formed crystals. ■ Monitor blood glucose closely, especially in patients with diabetes. ■ See Precautions, Drug/Lab Interactions, and Antidote.

Patient Education:

A patient medication guide is available from the manufacturer. ■ Discontinue moxifloxacin and promptly report the development of any severe adverse reaction. ■ Review medicines and disease states with physician or pharmacist before initiating therapy. ■ Drink fluids liberally. ■ Inform physician of any history of myasthenia gravis. ■ Patients with a history of myasthenia gravis should avoid use of moxifloxacin. ■ Report skin rash or any other hypersensitivity reaction promptly. ■ Promptly report development of any CNS side effects (e.g., convulsions, dizziness, light-headedness, change in mood or behavior). ■ Inform physician of any history of seizures. ■ Request assistance with ambulation; may cause dizziness and light-headedness. Use caution in tasks that require alertness. ■ Promptly report tendon pain or inflammation, weakness, or inability to use a joint; rest and refrain from exercise. ■ Promptly report burning, numbness, pain, tingling, or weakness in extremities. Nerve damage can be permanent. ■ Promptly report S/S of liver injury (e.g., dark-colored urine, fever, itching, jaundice [yellowing of skin or whites of eyes], light-colored bowel movements, loss of appetite, nausea, right upper quadrant tenderness, tiredness, vomiting, weakness). ■ May produce changes in ECG. Report fainting spells or palpitations promptly. ■ May alter glucose control in diabetic patients on insulin or oral therapy. Monitor glucose carefully. Discontinue moxifloxacin and contact physician if hypoglycemic reaction occurs. ■ Photosensitivity has occurred in patients receiving other quinolones and, infrequently, moxifloxacin. It is best to avoid excessive sunlight or artificial ultraviolet light. May cause severe sunburn; wear protective clothing, use sunscreen, and wear dark glasses outdoors. Report a sunburn-like reaction or skin eruption promptly. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Seek emergency medical care if sudden chest, stomach, or back pain is experienced. ■ See Precautions, Monitor, Drug/Lab Interactions, and Antidote.

Maternal/Child:

Safety for use in pregnancy not established. Based on animal studies, moxifloxacin may cause fetal harm. Benefit must outweigh risk to fetus. ■ Use caution if breast-feeding infants; consider risk versus benefit. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established. ■ Quinolones have caused erosion of cartilage in weight-bearing joints and other signs of arthropathy in juvenile animals; however, they have been used in infants and children to treat serious infections unresponsive to other antibiotic regimens.

Elderly:

Safety and effectiveness similar to that of younger adults; however, elderly may experience an increased risk of side effects (e.g., aortic aneurysm and dissection, CNS effects, tendinitis, tendon rupture, risk of QT prolongation). ■ See Precautions.

DRUG/LAB INTERACTIONS

May cause ventricular arrhythmias or torsades de pointes with **drugs that prolong the QT interval,** such as **Class Ia antiarrhythmic agents** (e.g., quinidine, procainamide), **Class III antiarrhythmic agents** (e.g., amiodarone, sotalol), **phenothiazines, tricyclic antidepressants**. Use with caution; see Precautions. ■ Risk of CNS stimulation and seizures may be increased with concurrent use of **NSAIDs**. ■ May cause hyperglycemia and hypoglycemia with concurrent administration of **antidiabetic agents**; monitoring of blood glucose recommended. ■ May enhance the effects of **warfarin**; monitoring of PT or INR is recommended with concomitant use. ■ See literature for additional drug/drug interactions on transfer to oral moxifloxacin. ■ May cause a false-positive when **testing urine for opiates;** more specific testing methods may be indicated.

SIDE EFFECTS

Diarrhea, dizziness, headache, and nausea were most common and described as mild to moderate in severity. Other side effects reported in 1% or more of patients included abdominal pain, anemia, constipation, dyspepsia, elevated alanine aminotransferase, fever, hypokalemia, insomnia, and vomiting. Capable of numerous other reactions in fewer than 1% of patients. Some of these reactions include cardiovascular effects (e.g., cardiac arrest, palpitations, QT interval prolongation, tachycardia, torsades de pointes, vasodilation, ventricular tachyarrhythmias); CDAD; CNS stimulation (e.g., anxiety, confusion, depression, hallucinations, insomnia, nightmares, paranoia, restlessness, seizures, suicidal thoughts, tremor); hepatic failure; hepatitis and jaundice (predominantly cholestatic); hyperglycemia or hypoglycemia; hypersensitivity reactions (e.g., anaphylaxis, cardiovascular collapse, death, dyspnea, edema [facial, laryngeal, or pharyngeal], hypotension, itching, rash, shock, urticaria); hypotension; increased bilirubin; increased intracranial pressure; pain, inflammation, and ruptures of the shoulder, hand, and Achilles tendon; peripheral neuropathy (e.g., pain, burning, tingling, numbness and/or weakness [see Precautions, Monitor]); photosensitivity/phototoxicity; prolonged PT and INR; Stevens-Johnson syndrome; syncope; and toxic psychoses; see Precautions.

Post-Marketing:

Acute renal insufficiency or failure, allergic pneumonitis; arthralgia; exacerbation of myasthenia gravis; hearing impairment, including deafness (reversible in most); hematologic abnormalities (agranulocytosis, anemia [hemolytic and aplastic], leukopenia, pancytopenia, thrombocytopenia, thrombotic thrombocytopenic purpura); interstitial nephritis; liver abnormalities (e.g., acute hepatic necrosis or failure, hepatitis, jaundice); muscle weakness; myalgia; peripheral neuropathy; polyneuropathy; rash; serum sickness; severe dermatologic reactions (e.g., toxic epidermal necrolysis [Lyell's syndrome], Stevens-Johnson syndrome); suicidal ideation/thoughts; vasculitis; vision loss (transient in most cases).

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically or will resolve with continued dosing (e.g., dizziness, lightheadedness); monitor closely. Discontinue at first sign of hypersensitivity (e.g., skin rash), CDAD, CNS symptoms, dermatologic reactions, hypoglycemic reactions, phototoxicity, symptoms of peripheral neuropathy, or tendon rupture. Treat hypersensitivity reactions as indicated with epinephrine, airway management, oxygen, IV fluids, antihistamines, corticosteroids, and pressor amines. Treat CNS symptoms as indicated. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Complete rest is indicated for an affected tendon until treatment is available. Discontinue if photosensitivity occurs. Monitoring of the ECG and adequate hydration are indicated in overdose. No specific antidote. Less than 10% of moxifloxacin and its glucuronide metabolite are removed by CAPD or hemodialysis.

MULTIVITAMIN INFUSION

(mul-ti-**VI**-tah-min in-**FU**-zhun)
Infuvite Adult, Infuvite Pediatric, M.V.I.-12, M.V.I. Adult, M.V.I. Pediatric
Nutritional supplement (vitamin)

USUAL DOSE

Multiples of the daily dose may be given or additional doses of individual vitamins in patients (adult and pediatric patients) with multiple vitamin deficiencies or markedly increased requirements. Individual components may be indicated in specific or long-standing deficiencies. Monitor blood vitamin concentrations to ensure maintenance of adequate levels. Formulations differ in the amount of each vitamin supplied and in their content (some contain vitamin K [e.g., ***M.V.I. Adult and Pediatric, Infuvite (Adult and Pediatric)***], and others do not [e.g., ***M.V.I.-12***]); see Drug/Lab Interactions.

All adult formulations:

One 5- to 10-mL dose every 24 hours.

PEDIATRIC DOSE

See Maternal/Child.

Infuvite Pediatric

Supplemental vitamin A may be required for low-birth-weight infants.

Less than 1 kg:

30% of the contents of vial 1 and vial 2 (1.2 mL of vial 1 and 0.3 mL of vial 2).

1 to 3 kg:

65% of the contents of vial 1 and vial 2 (2.6 mL of vial 1 and 0.65 mL of vial 2).

Over 3 kg to 11 years of age:

Entire contents of vial 1 (4 mL) and entire contents of vial 2 (1 mL).

M.V.I. Pediatric

Less than 1 kg:

1.5 mL/24 hr.

1 to 3 kg:

3.25 mL/24 hr.

Over 3 kg to 11 years of age:

5 mL/24 hr.

DILUTION

Various preparations, including pharmacy bulk packages. Most may be reconstituted with 5 mL of SWFI or supplied diluent. All preparations must be further diluted in at least 500 mL but preferably 1,000 mL of IV fluids. Soluble in commonly used infusion fluids, including dextrose, saline, electrolyte replacement fluids, plasma, and selected protein amino acid products. Do not use if any crystals have formed. When reconstituted as directed, ***Infuvite Adult*** contains no more than 70 mcg/L of aluminum. M.V.I.-12 also contains aluminum.

Pediatric dilution:

Infuvite Pediatric and M.V.I. Pediatric:

Each dose should be added to at least 100 mL of dextrose, saline, or other **compatible** infusion solution. When reconstituted as directed, ***M.V.I. Pediatric*** contains no more than 42 mcg/L of aluminum, and ***Infuvite Pediatric*** contains no more than 30 mcg/L of aluminum; see Precautions. See Maternal/Child.

Storage:

Before use, refrigerate at 2° to 8° C (36° to 46° F) protected from light. Manufacturers recommend immediate use of fully diluted Infuvite Pediatric and M.V.I. Adult and Pediatric. Fully diluted M.V.I.-12 and Infuvite Adult should be refrigerated and used within 24 hours. Once a pharmacy bulk vial has been penetrated, complete dispensing within 4 hours. Mixed solution may be stored for up to 4 hours refrigerated.

COMPATIBILITY

Compatibility may vary with preparation; consult prescribing information for specifics of a preparation. Direct addition to IV fat emulsions is not recommended. Some manufacturers suggest that admixture or **Y-site** administration with vitamin solutions should be avoided. Alkaline or other alkaline solutions (e.g., acetazolamide, aminophylline, chlorothiazide, sodium bicarbonate), as well as ampicillin and tetracycline, are listed as **incompatible** by one manufacturer. Folic acid may be unstable with calcium salts. ***All formulations must be diluted in infusion solutions.***

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose given as an infusion at prescribed rate of infusion fluids. **Do not administer** as a direct, undiluted IV injection; may cause dizziness, faintness, and tissue irritation.

ACTIONS

A multiple vitamin solution containing fat-soluble and water-soluble vitamins in an aqueous solution. Provides B complex and vitamins A, D, and E. Some multivitamin preparations presently available do not contain vitamin K. ***Infuvite Adult, M.V.I. Adult, Infuvite Pediatric, and M.V.I. Pediatric*** do contain vitamin K. Provides daily requirements or corrects an existing deficiency.

INDICATIONS AND USES

A daily multivitamin maintenance supplement for patients receiving parenteral nutrition. Provides the necessary vitamins required to maintain the body's normal resistance and repair processes. Also used in situations such as surgery, trauma, burns, severe infectious disease, and comatose states, which may provoke a stress response and alteration in the body's metabolic demands. Used when oral administration is contraindicated, not possible, or insufficient. Solutions without vitamin K are indicated for patients on warfarin anticoagulant therapy who are receiving parenteral nutrition.

CONTRAINDICATIONS

Known hypersensitivity to thiamine hydrochloride or other product components; pre-existing hypervitaminosis. ■ Contraindicated prior to blood sampling for detection of megaloblastic anemia. Folic acid and cyanocobalamin in formulation may mask serum deficits.

PRECAUTIONS

Solutions containing multivitamins may contain aluminum. In patients with renal impairment, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. ■ Blood draws for the detection of folic acid and cyanocobalamin deficiencies are indicated before administration to patients with megaloblastic anemia. ■ See Drug/Lab Interactions.

Monitor:

Monitor VS. ■ Monitor for any symptoms of a hypersensitivity reaction. ■ Moderate increase in ALT may occur in patients with active inflammatory enterocolitis. Usually reversible following discontinuation of vitamin infusion. Monitoring of ALT levels suggested. ■ Monitor vitamin A levels in patients with liver disease and/or high alcohol consumption. ■ Monitor renal function, aluminum, calcium, phosphorous, and vitamin A levels in patients with impaired renal function. ■ Measure blood vitamin concentrations periodically in patients receiving parenteral nutrition to determine if vitamin deficiencies or excesses are developing. Blood levels of A, C, D, and folic acid may decline in patients receiving parenteral multivitamins as their sole source of vitamins for 4 to 6 months. ■ See Precautions, Maternal/Child, and Drug/Lab Interactions.

Patient Education:

Report any S/S of hypersensitivity reactions (e.g., digital edema, periorbital edema, urticaria). ■ Patients with renal impairment should promptly report any nausea, vomiting, headache, dizziness, or blurred vision. ■ Promptly report agitation, anxiety, dizziness, double vision, erythema, headache, itching, and rash. ■ Periodic monitoring of blood vitamin concentrations is indicated.

Maternal/Child:

Recommendations for use during pregnancy vary by product. Range is from vitamin needs may exceed those of nonpregnant women to safety for use in pregnancy not established; use only if clearly needed. ■ Recommendations for use during breast-feeding vary by product. Range is from vitamin needs may exceed those of nonpregnant women to not known if secreted in breast milk; use caution if required during breast-feeding. ■ Safety and effectiveness of adult formulations and MVI-12 for use in pediatric patients under 11 years of age have not been established. ■ See Precautions.

Elderly:

Consider age-related decreased organ function and/or medical problems. No identified differences in response between the elderly and younger patients.

DRUG/LAB INTERACTIONS

See specific vitamins for detailed information.

SIDE EFFECTS

Rare when administered as recommended: Agitation; allergic reactions including anaphylaxis, angioedema, periorbital and digital edema, shortness of breath, urticaria, and wheezing; anxiety; diplopia; dizziness; erythema; fainting; headache; pruritus; rash. Vitamin A and vitamin D hypervitaminosis (symptomatology related to hypercalcemia) may occur with prolonged use of significant doses.

ANTIDOTE

With onset of any side effect, discontinue administration immediately and notify physician. Treat anaphylaxis or resuscitate as necessary.

MYCOPHENOLATE MOFETIL HYDROCHLORIDE BBW

(**my**-koh-**FEN**-oh-layt **MAH**-fuh-teel hy-droh-**KLOR**-eyed)
CellCept Intravenous
Immunosuppressant
pH 2.4 to 4.1

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor. Verify pregnancy status; see Maternal/Child.

Used in combination with cyclosporine (Sandimmune) and corticosteroids. Oral form should be used as soon as tolerated by the patient. Initial dose should be given within 24 hours of transplantation. The IV preparation may be used for up to 14 days.

Kidney or liver transplant:

1 Gm as an infusion twice daily (total daily dose of 2 Gm).

Heart transplant:

1.5 Gm as an infusion twice daily (total daily dose of 3 Gm).

PEDIATRIC DOSE

Limited data available; see Indications and Uses and product insert. Safety and efficacy of IV formulation not established. Usually given orally.

DOSE ADJUSTMENTS

No dose adjustments are indicated in renal transplant patients who experience delayed graft function postoperatively. ■ Avoid doses greater than 1 Gm twice daily in renal transplant patients with severe chronic renal impairments (GFR less than 25 mL/min/1.73 M^2) outside the immediate posttransplant period. ■ Data not available for cardiac or hepatic transplant patients with severe chronic renal impairment; potential benefits must outweigh risks. ■ Reduce dose or interrupt the dosing cycle if neutropenia (ANC less than 1.3 × 10^3 [1,300 cells/mm^3]) occurs. ■ Dose adjustment not indicated in impaired liver function. ■ See Precautions/Monitor.

DILUTION

Specific techniques required; see Precautions. Use caution in handling and preparation. Avoid skin contact with the solution. If skin contact occurs, wash thoroughly with soap and water; rinse eyes with plain water.

Reconstitute each 500-mg vial with 14 mL of D5W (500 mg/15 mL). Shake gently to dissolve. Discard if particulate matter or discoloration is observed or if a lack of vacuum in vial is noted when diluent is added. To achieve a final concentration of 6 mg/mL, each 500 mg must be further diluted with 70 mL of D5W (1 Gm with 140 mL; 1.5 Gm with 210 mL).

Filters:

Not required by manufacturer; however, no significant loss of potency is expected with the use of a filter.

Storage:

Store powder and reconstituted or diluted solutions at 15° to 30° C (59° to 86° F). Most desired storage temperature is 25° C (77° F). Reconstituted or diluted solutions are best used immediately after preparation. Keep reconstituted or diluted solutions at CRT; the infusion must begin within 4 hours of reconstitution/dilution.

COMPATIBILITY

Manufacturer states, “Mycophenolate is **incompatible** with other IV solutions and should not be mixed or administered concurrently via the same infusion catheter with other intravenous drugs or infusion admixtures.”

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose must be given as an infusion over a minimum of 2 hours. **Must not be** administered by rapid or bolus IV injection. Rapid infusion increases the risk of local adverse reactions such as phlebitis and thrombosis.

ACTIONS

A hydrochloride salt of mycophenolate mofetil. An antimetabolite immunosuppressive agent. Has a potent cytostatic effect on lymphocytes, inhibiting proliferation of both B- and T-lymphocytes. It also suppresses antibody formation by B-lymphocytes. Rapidly and completely metabolized to mycophenolic acid (MPA), its active metabolite. MPA is then metabolized predominantly to its inactive metabolite, mycophenolic acid glucuronide (MPAG). Secondary peak in plasma MPA concentration is usually noted 6 to 12 hours postdose. Enterohepatic recirculation is thought to contribute to MPA concentrations. Both MPA and MPAG are highly bound to albumin. In patients with renal impairment or delayed graft function, levels of MPAG may be elevated. Binding of MPA may then be reduced as a result of competition between MPAG and MPA. Plasma concentrations of metabolites are increased in patients with renal impairment. Half-life is 11.4 to 24.4 hours. Excreted primarily as MPAG in urine. Small amount excreted in feces.

INDICATIONS AND USES

Used as part of an immunosuppressive regimen that includes cyclosporine and corticosteroids. ■ Prophylaxis of acute organ rejection in patients receiving allogeneic kidney, heart or liver transplants. ■ Capsules, tablets, and oral solution approved for prevention of rejection in pediatric renal transplant patients.

CONTRAINDICATIONS

Hypersensitivity to mycophenolate mofetil, mycophenolic acid, any component of the drug product, or polysorbate 80 (TWEEN).

PRECAUTIONS (International units [IU])

For IV use only. ■ Use caution in handling and preparation. Avoid skin contact with the solution. If contact occurs, wash thoroughly with soap and water; rinse eyes with plain water. Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Usually administered by or under the direction of a physician experienced in immunosuppressive therapy and the management of organ transplant patients. Adequate laboratory and supportive medical resources must be available. ■ Risk of developing lymphoproliferative diseases, lymphomas, and other malignancies, particularly of the skin, is increased. Appears to be related to the intensity and duration of immunosuppression rather than to any specific agent. ■ Posttransplant lymphoproliferative disorder has been reported in organ transplant patients receiving mycophenolate with other immunosuppressants. Most cases appear to be related to Epstein-Barr virus (EBV) infection. Risk is greatest in patients who are EBV seronegative. ■ Patients receiving immunosuppressants have increased susceptibility to bacterial, viral, fungal, and protozoal infections, including opportunistic infections and viral reactivation of hepatitis B and C, which may lead to hospitalizations and fatal outcomes. Serious viral infections that have been reported include polyomavirus-associated nephropathy (PVAN), JC virus–associated progressive multifocal leukoencephalopathy (PML), cytomegalovirus (CMV) infections, and reactivation of hepatitis B (HBV) or hepatitis C (HCV). Reduction in immunosuppression should be considered for patients who develop evidence of new or reactivated viral infections. Physicians should also consider the risk that reduced immunosuppression presents to the functioning allograft. ■ PML has been reported. PML is a serious progressive neurologic disorder caused by infection of the CNS by JC virus, a member of the polyomavirus family. It typically occurs in immunocompromised patients. PML is rare but may result in irreversible neurologic deterioration and death, and there is no known effective treatment. Hemiparesis, apathy, confusion, cognitive deficiencies, and ataxia are the most commonly observed clinical signs. ■ PVAN, especially due to BK virus infection, is associated with serious outcomes, including deterioration in renal function and renal graft loss. Reduction in immunosuppression may be indicated. ■ Risk of CMV viremia and CMV disease is highest among transplant recipients who are seronegative for CMV at time of transplant and receive a graft from a CMV-seropositive donor. ■ Severe neutropenia has been reported; see Monitor. ■ Pure red cell aplasia (PRCA) has been reported in patients receiving mycophenolate in combination with other immunosuppressive agents. May be reversible with dose reduction or discontinuation of mycophenolate. In transplant patients, reduced immunosuppression may place the graft at risk. ■ Has been associated with an increased incidence of GI adverse effects (e.g., GI tract ulceration, hemorrhage, and/or perforation). Use caution in patients with active serious gastrointestinal disease. ■ Use with caution in patients with hepatic insufficiency. Metabolism of MPA may be affected by certain types of hepatic disease. ■ Use caution in patients with severe chronic renal impairment; see Dose Adjustments. ■ Avoid use in patients with selected rare hereditary deficiencies of hypoxanthine-guanine phosphoribosyl-transferase, such as Lesch-Nyhan and Kelley-Seegmiller syndromes; may exacerbate disease symptoms. ■ See Monitor, Patient Education, and Maternal/Child.

Monitor:

Obtain baseline CBC with differential before treatment. Repeat weekly during the first month, twice monthly for the second and third months, then monthly thereafter for the first year. ■ Monitor for neutropenia. Has been observed most frequently in the period from 31 to 180 days posttransplant. May be due to mycophenolate, concomitant medications, viral infections, or some combination of these causes. If neutropenia develops (ANC less than 1,300 cells/mm^3), mycophenolate should be interrupted or the dose reduced. Appropriate diagnostic tests and treatment should be instituted. ■ Monitor for S/S of infection. ■ Assess neurologic status frequently. ■ Monitor patients infected with HBV or HCV for clinical and laboratory signs suggestive of reactivation of infection. ■ Monitor for S/S of organ rejection. ■ Monitor for S/S of lymphoma or other malignancies. ■ Monitor patients with severe chronic renal impairment and patients with delayed graft function closely. See Dose Adjustments and Actions.

Patient Education:

Read the manufacturer’s medication guide before beginning treatment with mycophenolate. ■ In women of childbearing age, a pregnancy test is required immediately before starting mycophenolate. Test should be repeated in 8 to 10 days. Repeat pregnancy tests should be performed during routine follow-up visits. Effective contraception must be used during therapy and for 6 weeks following cessation of therapy. Females with reproductive potential must be counseled regarding pregnancy prevention and planning. Females with reproductive potential include girls who have entered puberty and all women who have a uterus and have not passed through menopause (menopause must be confirmed). See manufacturer’s prescribing information for acceptable contraceptive methods. Birth control pills alone may be ineffective. If a pregnancy occurs, do not stop mycophenolate; call your health care provider. See Maternal/Child. ■ Alternative immunosuppressants with less potential for embryo-fetal toxicity should be considered in patients who are considering pregnancy. ■ Promptly report any S/S of infection or bone marrow suppression (e.g., unexpected bruising, bleeding). May cause serious infections. ■ May increase risk of lymphoproliferative disease and some other malignancies. ■ Risk of skin cancer may be increased. Reduce exposure to sunlight and UV light. Wear protective clothing and use a sunscreen with a high protection factor. ■ Promptly report any S/S of GI toxicity (e.g., abdominal pain, bleeding). ■ Cooperation with repeated laboratory tests imperative. ■ Review medications with the physician responsible for mycophenolate therapy. ■ Do not donate blood during therapy or for at least 6 weeks after discontinuation of mycophenolate because the blood or blood product could be administered to a woman of reproductive potential or to a pregnant woman. ■ Sexually active male patients and/or their female partners should use effective contraception during treatment of the male patient and for at least 90 days after cessation of treatment. ■ Do not donate semen during therapy and for 90 days after discontinuation of mycophenolate. ■ May affect ability to drive or operate machinery. Avoid tasks that require alertness if somnolence, confusion, dizziness, tremor, or hypotension is experienced during treatment with mycophenolate. ■ See Appendix D, p. 1311.

Maternal/Child:

Increased risk of first-trimester pregnancy loss and increased risk of congenital malformations, especially external ear and other facial abnormalities (including cleft lip and palate) and anomalies of the distal limbs, heart, esophagus, kidney, and nervous system. See manufacturer’s literature for details. Avoid use of mycophenolate during pregnancy if safer treatment options are available. Use during pregnancy only if benefit justifies risk; should pregnancy occur during treatment, discuss the desirability of continuing the pregnancy. Women using mycophenolate at any time during pregnancy are encouraged to enroll in the National Transplantation Pregnancy Registry. Patients considering pregnancy should discuss with their physician appropriate alternative immunosuppressants with less potential for embryo-fetal toxicity. A negative serum or urine pregnancy test with a sensitivity of at least 25 mIU/mL immediately before beginning therapy is indicated in all women of childbearing age. Repeat testing required. Effective contraception required before, during, and after use. See Patient Education. ■ There are no data on the presence of mycophenolate in human milk or the effects on milk production; use caution. ■ Safety and effectiveness of IV formulation for use in pediatric patients not established but has been used; see Indications.

Elderly:

No specific recommendations. Consider age-related decreased organ function and/or additional medical problems and medications. May be at increased risk for certain adverse reactions (e.g., certain infections [including CMV tissue invasive disease] and possibly GI hemorrhage and pulmonary edema). Observe carefully.

DRUG/LAB INTERACTIONS

Several drugs have the potential to alter systemic mycophenolic acid (MPA) exposure when co-administered with mycophenolate. Determination of MPA plasma concentrations before and after making changes to immunosuppressive therapy, or when adding or discontinuing concomitant medications, may be appropriate to ensure MPA concentrations remain stable. ■ **Cyclosporine** may decrease serum levels of MPA (mycophenolate). Monitor levels closely when cyclosporine is added or removed from a drug regimen containing mycophenolate. ■ Use caution with **drugs that**

interfere with enterohepatic recirculation or alter the intestinal flora (e.g., cholestyramine, rifampin, sulfamethoxazole/trimethoprim, selected antimicrobial classes [e.g., aminoglycosides, cephalosporins, fluoroquinolones, and penicillins]); may decrease MPA systemic exposure, reducing mycophenolate efficacy. ■ When given concomitantly with **drugs that undergo renal tubular secretion** (e.g., acyclovir, ganciclovir, probenecid, valacyclovir, valganciclovir), mycophenolate's metabolite (MPAG) may compete with secretion of these drugs, increasing plasma concentrations and/or adverse reactions associated with these drugs; monitoring of drug-related adverse reactions is recommended. ■ **Oral contraceptives and other hormonal contraceptives** (e.g., transdermal patch, vaginal ring, injection, and implant) may be less effective; use additional barrier contraceptive measures; see manufacturer's prescribing information. ■ Concomitant administration of **drugs that induce glucuronidation** (e.g., telmisartan) decreases MPA systemic exposure, potentially reducing mycophenolate efficacy. ■ Concomitant administration of **drugs that inhibit glucuronidation** (e.g., isavuconazole) increase MPA systemic exposure, potentially increasing the risk of mycophenolate-related adverse reactions. ■ Do not use **live virus vaccines** in patients receiving mycophenolate; vaccinations may be less effective. See Patient Education.

SIDE EFFECTS

Diarrhea, infection, leukopenia, and vomiting occur most frequently. Other reactions that occurred in at least 20% of patients during clinical trials included abdominal pain, asthenia, bone marrow suppression (e.g., anemia, ecchymosis, leukocytosis, leukopenia, neutropenia, thrombocytopenia), constipation, cough, creatinine and BUN increase, decreased appetite, depression, dizziness, dyspepsia, dyspnea, edema, fever, headache, hypercholesterolemia, hyperglycemia, hyperkalemia, hypertension, hypocalcemia, hypokalemia, hypomagnesemia, hypotension, infection, insomnia, lactic dehydrogenase increase, LFT abnormalities, and nausea. 2 Gm/day demonstrated an overall better safety profile than 3 Gm/day. Serious adverse reactions included blood dyscrasias, embryo-fetal toxicity, GI complications, lymphomas and other malignancies, PML, renal impairment, and serious infections; see Precautions.

Post-Marketing:

Bone marrow failure, bronchiectasis, colitis, embryo-fetal toxicity (including congenital malformations and spontaneous abortions [mainly in the first trimester]; see manufacturer's prescribing information), hypogammaglobulinemia, infections (e.g., atypical mycobacterial infections; endocarditis; meningitis; polyomavirus-associated neuropathy [PVAN], especially due to BK virus; progressive multifocal leukoencephalopathy [PML]; protozoal infections; TB; viral reactivation in patients infected with HBV or HCV), interstitial lung disorders (including fatal pulmonary fibrosis), lymphocele, pancreatitis, pure red cell aplasia, venous thrombosis.

ANTIDOTE

Notify the physician of all side effects. Most can be treated symptomatically. Drug may be decreased or discontinued or other immunosuppressive agents utilized. Some side effects (e.g., neutropenia) may require temporary reduction of dosage or withholding of treatment. Consider reducing the amount of immunosuppression in patients who develop PML, taking into account the risk this may represent to the graft. At clinically encountered concentrations, MPA and MPAG are not usually removed by hemodialysis. However, at high concentrations (greater than 100 mcg/mL) small amounts of MPAG are removed. MPA may be removed by bile acid sequestrants such as cholestyramine.

Generic drugs: N

NAFCILLIN SODIUM
NALBUPHINE HYDROCHLORIDE
NALOXONE HYDROCHLORIDE

NOREPINEPHRINE BITARTRATE

N

NAFCILLIN SODIUM

(naf-**SILL**-in **SO**-dee-um)
Nallpen 🍁
Antibacterial (penicillinase-resistant penicillin)
pH 6 to 8.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Nafcillin:

500 mg to 1 Gm every 4 hours. Up to 12 Gm in 24 hours has been used in severe infections. Duration of therapy varies with the type and severity of infection and with the overall condition of the patient; determine by the clinical and bacteriologic response. Usual duration of therapy is at least 14 days for severe staphylococcal infections and longer (4 to 6 weeks) for endocarditis and osteomyelitis.

Endocarditis, meningitis, osteomyelitis, or pericarditis:

1.5 to 2 Gm every 4 to 6 hours.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established. All pediatric IV doses are unlabeled; see Maternal/Child. Limited clinical experience with IV route in neonates and infants. Maximum dose is 12 Gm/24 hr.

Pediatric patients over 1 month of age:

Moderate infections:

100 to 150 mg/kg/day in equally divided doses every 6 hours (25 to 37.5 mg/kg every 6 hours). Maximum daily dose is 4 Gm/day.

Severe infections:

150 to 200 mg/kg/24 hr in equally divided doses every 4 to 6 hours (25 to 33.3 mg/kg every 4 hours or 37.5 to 50 mg/kg every 6 hours). Use the higher dose (e.g., 200 mg/kg/day in equally divided doses every 4 to 6 hours [33.3 mg/kg every 4 hours or 50

mg/kg every 6 hours]) in infections such as meningitis and endocarditis. Maximum dose is 12 Gm/day.

NEONATAL DOSE

Safety and effectiveness for use in neonates not established. All pediatric doses are unlabeled; see Maternal/Child. Limited clinical experience with IV route in neonates and infants.

25 mg/kg with the interval adjusted based on age and weight as follows:

0 to 7 days of age and under 2,000 Gm:

Every 12 hours.

Over 7 days of age and under 1,200 Gm:

Every 12 hours.

Over 7 days of age and 1,200 to 2,000 Gm:

Every 8 hours.

0 to 7 days of age and over 2,000 Gm:

Every 8 hours.

Over 7 days of age and over 2,000 Gm:

Every 6 hours.

Increase dose to 50 mg/kg every 6, 8, or 12 hours in meningitis.

DOSE ADJUSTMENTS

Dose adjustment not required for patients with renal dysfunction, including those receiving hemodialysis.

DILUTION

Each 500-mg vial is reconstituted with 1.7 mL of SWFI, NS, or BWFI (1-Gm vial with 3.4 mL, 2-Gm vial with 6.6 mL). Each 1 mL equals 250 mg. Further dilute each dose with a minimum of 15 to 30 mL of SWFI, NS, or ½NS, or other **compatible** IV solutions (see chart on inside back cover or literature). Further dilution and final concentration determined by method of administration (direct IV injection, IVPB, or infusion). Concentration may range from 2 to 250 mg/mL. Available prediluted and in ADD-Vantage vials for use with ADD-Vantage infusion containers. May be given through Y-site or with additive tubing or may be added to larger volume of **compatible** solutions.

Filters:

Not required by manufacturer. Premixed and frozen solutions are filtered during manufacturing.

Storage:

Store unopened vials at CRT. Stability after reconstitution or further dilution is dependent on concentration, solution, and storage conditions; see individual manufacturer's prescribing information. Frozen, premixed solutions should be stored at −20° C (−4° F). Thaw at room temperature or under refrigeration. Thawed solutions are stable for 72 hours at RT or 21 days refrigerated. Do not refreeze.

COMPATIBILITY

Inactivated in solution with aminoglycosides (e.g., amikacin, gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. See Drug/Lab Interactions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

May be infused over 5 to 10 minutes.

Intermittent IV:

Administration over 30 to 60 minutes may decrease incidence of thrombophlebitis.

Infusion:

When diluted in large volumes of infusion fluids, give at rate prescribed.

ACTIONS

A semi-synthetic penicillinase-resistant penicillin, used for its bactericidal activity against gram-positive organisms, primarily penicillinase-producing staphylococci (methicillin-susceptible isolates only). Mode of action involves inhibition of bacterial cell wall biosynthesis. Highly resistant to inactivation by staphylococcal penicillinase. Readily distributes into most body fluids and tissues except the aqueous humor of the eye and spinal fluid. Binds to serum proteins, primarily albumin. Mainly eliminated by hepatic inactivation and excretion in bile; a small amount is excreted in urine. Half-life is 33 to 61 minutes. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of infections caused by penicillinase-producing staphylococci.

CONTRAINDICATIONS

Known hypersensitivity to any penicillin or cephalosporin (not absolute); see Precautions. Prediluted solutions containing dextrose may be contraindicated with known allergies to corn products.

PRECAUTIONS

Sensitivity studies necessary to determine susceptibility of the causative organism to penicillinase-resistant penicillins. Nafcillin should not be used in infections caused by an organism susceptible to penicillin G. If susceptibility tests indicate that infection is due to methicillin-resistant *Staphylococcus* species, therapy should be discontinued and alternative therapy provided. Modify antimicrobial treatment as indicated by C/S. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, nafcillin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Use with caution in patients with both impaired hepatic and renal function; elevated serum concentrations may cause neurotoxic reactions. See Dose Adjustments. ■ Hypersensitivity reactions, including fatalities, have been reported in patients receiving beta-lactam antibacterial drugs; most likely to occur in patients with a history of penicillin hypersensitivity or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Avoid prolonged use of the drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with nafcillin. ■ Manufacturer's premixed solutions contain dextrose; may be contraindicated in patients with an allergy to corn or corn products.

Monitor:

Obtain baseline CBC with differential, SCr, BUN, and urinalysis, and monitor during treatment. ■ Obtain baseline serum bilirubin, AST, ALT, alkaline phosphate, and gamma glutamyl transferase, and monitor periodically during therapy, especially with high nafcillin doses. In worsening hepatic function, risk versus benefit of continued use should be re-evaluated. ■ Watch for early symptoms of a hypersensitivity reaction, especially in individuals with a history of allergic problems. ■ May cause thrombophlebitis, especially in the elderly or with too-rapid injection. Limit peripheral IV treatment to 24 to 48 hours when possible. Change to oral therapy as soon as practical. ■ Electrolyte imbalance and cardiac irregularities from sodium content are possible. Contains up to 3.3 mEq sodium/Gm. May aggravate CHF. Observe for hypokalemia. ■ See Drug/Lab Interactions.

Patient Education:

May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Use only if clearly needed. ■ May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Safety and effectiveness for the use of IV nafcillin in pediatric patients not established, but it is used; see Pediatric Dose. ■ Elimination rate markedly reduced in neonates and infants due to immature hepatic and renal function.

Elderly:

Response similar to that seen in younger adults. Consider age-related organ impairment and concomitant disease or drug therapy. Elderly patients may respond with a blunted natriuresis to salt loading, which can be clinically important with regard to diseases such as CHF. ■ May be at increased risk for thrombophlebitis. ■ See Precautions/Monitor and Dose Adjustments.

DRUG/LAB INTERACTIONS

May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Potentiated by **probenecid**; toxicity may result. ■ Synergistic when used in combination with **aminoglycosides** (e.g., amikacin, gentamicin). Synergism may be inconsistent; see Compatibility. ■ May decrease serum levels and effectiveness of **cyclosporine**. Monitor cyclosporine levels during concomitant use. ■ Inhibits effectiveness of **oral contraceptives;** breakthrough bleeding or pregnancy could result. ■ High doses (9 to 12 Gm daily) may decrease effects of **warfarin**; monitor PT up to 30 days after nafcillin completed. ■ May reduce effectiveness of **nifedipine** by reducing its serum plasma levels. ■ May cause **false values in common lab tests;** see literature.

SIDE EFFECTS

Bleeding abnormalities, bone marrow suppression (e.g., agranulocytosis, neutropenia), CDAD, diarrhea, hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, hypotension, laryngospasm, pruritus, rash, serum sickness–like symptoms, urticaria [may be immediate or delayed]), interstitial nephritis, local reactions (e.g., pain, phlebitis, thrombophlebitis, and occasionally skin sloughing with extravasation), nausea and vomiting, and renal tubular damage have been reported. Larger doses may cause neurologic adverse reactions, including convulsions, especially with concomitant impaired hepatic insufficiency and renal dysfunction. Elevation of liver transaminases and/or cholestasis may occur, specifically with higher doses.

ANTIDOTE

Notify physician immediately of any adverse symptoms. For severe symptoms discontinue the drug, treat hypersensitivity reaction (antihistamines, epinephrine, corticosteroids), and resuscitate as necessary. Hemodialysis or peritoneal dialysis is minimally effective in overdose. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Mild cases may respond to drug discontinuation alone.

NALBUPHINE HYDROCHLORIDE BBW

(**NAL**-byoo-feen hy-droh-**KLOR**-eyed)
Nubain 🍁
Narcotic analgesic (agonist-antagonist)
Anesthesia adjunct
pH 3.5 to 3.7

USUAL DOSE

Individualize dose, taking into account the patient's severity of pain, patient response, prior analgesic treatment experience, and risk factors for addiction, abuse, and misuse. Use lowest effective dose for the shortest duration consistent with the patient's treatment goals.

Pain control:

10 mg/70 kg. May repeat every 3 to 6 hours. In nontolerant patients, the recommended single maximum dose is 20 mg. Maximum total daily dose is 160 mg. Titrate to a dose and interval that provides adequate analgesia and minimizes adverse reactions; see Dose Adjustments.

Supplement to balanced anesthesia:

A loading dose of 0.3 to 3 mg/kg over 10 to 15 minutes. Maintain desired level of balanced anesthesia with 0.25 to 0.5 mg/kg as required. Administered only under the direction of the anesthesiologist.

DOSE ADJUSTMENTS

Reduced dose may be required in elderly, cachectic, or debilitated patients; in impaired liver or renal function; in patients with limited pulmonary reserve; and in the presence of other CNS depressants. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted.

Filters:

No data available from manufacturer.

Storage:

Store at CRT. Avoid freezing and/or prolonged exposure to light.

COMPATIBILITY

Manufacturer lists as **incompatible** with nafcillin and ketorolac.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Pain control:

Each 10 mg or fraction thereof over at least 2 to 3 minutes. Frequently titrated according to symptom relief and respiratory rate.

Supplement to balanced anesthesia:

See Usual Dose.

ACTIONS

A synthetic narcotic agonist-antagonist analgesic. Binds to kappa and mu receptors. Acts as an agonist at kappa receptors and as an antagonist at mu receptors. It equals morphine in analgesic effect. May produce the same degree of respiratory depression as an equianalgesic dose of morphine. However, it exhibits a ceiling effect such that dose increases greater than 30 mg do not produce further respiratory depression in the absence of other CNS-active medications that affect respiration. Has potent opioid antagonist activity at doses equal to or lower than its analgesic dose. When administered after or concurrently with a mu agonist opioid analgesic (e.g., morphine, oxymorphone, fentanyl), nalbuphine may partially reverse or block opioid-induced respiratory depression from the mu agonist analgesic. May precipitate withdrawal in patients dependent on opioid drugs. Onset of pain relief occurs within 2 to 3 minutes and lasts about 3 to 6 hours. Metabolized in the liver. Some excretion in feces and urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Management of pain severe enough to require an opioid analgesic and for which alternative treatments are inadequate. ■ Preoperative and postoperative analgesia. ■ Supplement to balanced anesthesia. ■ Obstetric analgesia during labor and delivery.

Unlabeled uses:

Opioid-induced pruritus.

Limitations of use:

Because of the risk for addiction, abuse, and misuse, even at recommended doses, reserve nalbuphine for use in patients for whom alternative treatment options (e.g., nonopioid analgesics or opioid combination products):

- Have not been tolerated or are not expected to be tolerated
- Have not provided adequate analgesia or are not expected to provide adequate analgesia

CONTRAINDICATIONS

Significant respiratory depression. ■ Acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment. ■ Known or suspected GI obstruction, including paralytic ileus. ■ Hypersensitivity to nalbuphine or its components.

PRECAUTIONS

Serious, life-threatening, or fatal respiratory depression may occur, particularly when used concomitantly with other opioids or CNS depressants. Respiratory depression may occur at any time, but risk is greatest during initiation of therapy or after a dose increase. To reduce the risk of respiratory depression, proper dosing and titration are essential. Overestimating the nalbuphine dose when converting patients from another opioid product can result in a fatal overdose with the first dose. ■ Adequate facilities should be available for monitoring and ventilation. An opioid antagonist (e.g., naloxone), resuscitative and intubation equipment, and oxygen should be readily available. ■ Use with extreme caution in patients with COPD, cor pulmonale, a substantially decreased respiratory reserve, hypoxia, hypercapnia, or pre-existing respiratory depression; these patients are at increased risk for decreased respiratory drive, including apnea, even at recommended doses. Consider using nonopioid analgesics, or administer under careful medical supervision at the lowest effective dose. ■ Use with caution and reduce initial doses in elderly, cachectic, or debilitated patients and in patients with severe impairment of hepatic, pulmonary, or renal function. Consider using nonopioid analgesics. ■ Cases of serotonin syndrome have been reported during concomitant use of nalbuphine with serotonergic drugs ■ Cases of adrenal insufficiency have been reported with opioid use, more often after more than 1 month of use. If adrenal insufficiency is diagnosed, treat with physiologic replacement doses of corticosteroids and wean the patient off the opioid to allow adrenal function to recover. Another opioid may be tried; some cases reported use of a different opioid without recurrence of adrenal insufficiency. ■ May cause severe hypotension, including orthostatic hypotension and syncope, in ambulatory patients or in any patient whose ability to maintain blood pressure has been compromised by depleted blood volume or concomitant administration of drugs that can cause hypotension (e.g., anesthetics, phenothiazines); see Drug/Lab Interactions. In patients with circulatory shock, nalbuphine-induced vasodilation may further reduce cardiac output and blood pressure. Use should be avoided. ■ Use caution in patients with head injury, brain tumors, or increased intracranial pressure. Respiratory depression may cause an increased P_{CO_2}, cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. Avoid use in patients with impaired consciousness or coma. ■ Use with caution in patients with biliary tract disease, including acute pancreatitis; may cause spasm of the sphincter of Oddi and diminish biliary and pancreatic secretions. ■ May increase the frequency of seizures in patients with a convulsive disorder, and may induce or aggravate seizures in some clinical settings. ■ Use caution in patients with myocardial infarction who have nausea and vomiting or compromised cardiac function; effect on heart not fully evaluated. ■ When used with anesthesia, a high incidence of bradycardia has been reported in patients who did not receive atropine preoperatively. ■ Should be administered as a supplement to general anesthesia only by persons specifically trained in the use of IV anesthetics and in the management of the respiratory effects of potent opioids. ■ Do not abruptly discontinue nalbuphine in patients who are physically dependent; dose must be tapered gradually. ■ Nalbuphine exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient's risk before prescribing nalbuphine, and monitor all patients regularly for the development of these behaviors and conditions. Strategies to reduce the risk of diversion or misuse should be used by health care facilities that use this and other controlled substances. ■ See prescribing information for further discussion regarding abuse, addiction, physical dependence, and tolerance. ■ Do not abruptly discontinue nalbuphine in patients who are physically dependent; dose must be tapered gradually.

Monitor:

Naloxone, oxygen, and equipment to establish and maintain an airway must be available. ■ Monitor for respiratory depression, especially during initiation of therapy (within the first 24 to 72 hours) or after a dose increase. ■ Assess baseline pain, reassess after administration of nalbuphine, and adjust dose or interval as required. ■ Monitor vital signs and oxygenation and observe patient frequently. ■ Keep patient supine to minimize side effects; orthostatic hypotension and fainting may occur. Observe closely during ambulation. ■ Monitor patients who may be susceptible to the intracranial effects of CO_2 retention for increasing intracranial pressure and signs of sedation and respiratory depression. ■ Monitor patients with biliary tract disease for worsening of symptoms. ■ Monitor patients with a history of seizure disorders for worsening seizure control. ■ Monitor for S/S of serotonin syndrome (e.g., mental status changes [e.g., agitation, coma, hallucinations], autonomic instability [e.g., hyperthermia, labile blood pressure, tachycardia], neuromuscular aberrations [e.g., hyperreflexia, incoordination, rigidity], and/or GI symptoms [e.g., diarrhea, nausea, vomiting]). Onset of symptoms may occur within hours to days of concomitant use of opioids with serotonergic drugs. ■ Adhere to prescribed bowel care regimen to avoid constipation and/or impaction. Maintain adequate hydration. ■ See Drug/Lab Interactions.

Patient Education:

Avoid use of alcohol, MAO inhibitors, or other CNS depressants. Review all medications for interactions. ■ Request assistance for ambulation. ■ Use caution performing any task that requires alertness; may cause dizziness, euphoria, and sedation. ■ Report unrelieved pain or side effects or S/S of serotonin syndrome. ■ May result in severe constipation. Scheduled bowel regimen recommended. ■ May result in addiction, abuse, and misuse.

Maternal/Child:

Use during pregnancy (other than labor and delivery) only if benefits justify risks. ■ Prolonged use of opioids during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life threatening if not recognized and treated. Infants born to mothers receiving nalbuphine during pregnancy should be monitored closely and treated for neonatal opioid withdrawal syndrome if indicated. See literature for treatment protocols. ■ Severe fetal bradycardia has been reported when nalbuphine is administered during labor. Take appropriate measures (e.g., fetal monitoring) to detect and manage potential adverse effects to the fetus. ■ Fetal and neonatal bradycardia, respiratory depression at birth, apnea, cyanosis, hypotonia, and a sinusoidal fetal heart rate pattern have been reported. Some of these events have been life threatening. Maternal or neonatal administration of naloxone may reverse these effects. Permanent neurologic damage attributed to fetal bradycardia has occurred. Fetal death has been reported when mothers received nalbuphine during labor and delivery. Use during labor and delivery only if clearly indicated and if benefit outweighs risk. Use during or immediately before labor is not recommended when other analgesic techniques are more appropriate. Newborns should be monitored for respiratory depression, apnea, bradycardia, and arrhythmias if nalbuphine has been used. ■ Use caution with breast-feeding. Monitor infants exposed to nalbuphine through breast milk for excess sedation and respiratory depression. Withdrawal symptoms can occur in breast-fed infants when maternal administration of an opioid analgesic is stopped or when breast-feeding is stopped. ■ Safety and effectiveness in pediatric patients under 18 years of age have not been established.

Elderly:

May be more sensitive to effects (e.g., respiratory depression, constipation, dizziness, urinary retention). Respiratory depression is the chief risk for elderly patients treated with opioids. ■ Analgesia should be effective with lower doses. ■ Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

Although nalbuphine possesses opioid antagonist activity, there is evidence that it will not antagonize an opioid analgesic administered just before, concurrently, or just after an injection of nalbuphine in nondependent patients. Therefore due to additive pharmacologic effects, the concomitant use of other opioid analgesics, benzodiazepines, or other CNS depressants may result in profound sedation, respiratory depression, coma, and death. Reserve concomitant use for patients for whom alternative treatment options are inadequate. Use minimum effective dose for the shortest duration possible, and monitor for S/S of respiratory depression and sedation. ■ Serotonin syndrome has been reported with the concomitant use of opioids, including nalbuphine, and other **drugs that affect the serotonergic neurotransmitter system** (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin and norepinephrine reuptake inhibitors [SNRIs], tricyclic antidepressants [TCAs], triptans, 5-HT$_3$ receptor antagonists, mirtazapine, trazodone, tramadol, MAO inhibitors, linezolid, and IV methylene blue). Careful observation, particularly during treatment initiation and dose adjustment, is required with concomitant use. ■ Severe and unpredictable potentiation of **MAO inhibitors** has been reported. MAO inhibitor interactions may manifest as serotonin syndrome or opioid toxicity (e.g., respiratory depression, coma). Use of nalbuphine is not recommended for patients taking MAOIs or within 14 days of stopping such treatment. If urgent use of an opioid is necessary, use test doses and frequent titration of small doses to treat pain while closely monitoring BP and S/S of CNS and respiratory depression. ■ Nalbuphine may enhance the neuromuscular blocking action of **skeletal muscle relaxants**, increasing the degree of respiratory depression. Monitor patient and decrease dose if indicated. ■ Opioids can reduce the efficacy of **diuretics** by inducing the release of antidiuretic hormone. Increase dose of diuretic if needed. ■ Concomitant use with **anticholinergic drugs** may increase the risk of urinary retention and/or severe constipation, which may lead to paralytic ileus. ■ Use in patients who are receiving a full **opioid agonist** analgesic may reduce the analgesic effect and/or precipitate withdrawal symptoms. Avoid concomitant use. ■ Depending on the test used, nalbuphine may interfere with enzymatic methods for the detection of **opiates**.

SIDE EFFECTS

Sedation is the most commonly reported adverse reaction. Less frequent adverse reactions are dizziness/vertigo, dry mouth, headache, nausea and vomiting, and sweaty/clammy skin. Adverse reactions that occur in 1% or fewer of patients are abdominal cramps, asthma, bitter taste, blurred vision, bradycardia, burning, CNS effects (e.g., confusion, crying, depression, dysphoria, euphoria, faintness, feeling of heaviness, floating, hallucinations, hostility, nervousness, restlessness, tingling, unreality, and unusual dreams), dyspepsia, dyspnea, flushing and warmth, hypersensitivity reactions (e.g., anaphylaxic/anaphylactoid reactions, bronchospasm, diaphoresis, edema, nausea and vomiting, pruritus, rash, shakiness, stridor, weakness, and wheezing), hypertension, hypotension, itching, respiratory depression, speech difficulties, tachycardia, urinary urgency, and urticaria.

Post-Marketing:

Abdominal pain, adrenal insufficiency, agitation, anxiety, depressed level of consciousness, fever, injection site reaction, pulmonary edema, seizures, serotonin syndrome, somnolence, and tremor. Death from severe allergic reactions has been reported. Fetal death has been reported when mothers received nalbuphine during labor and delivery.

Overdose:

Acute overdose with nalbuphine alone can be manifested by dysphoria and respiratory depression. Acute overdose with nalbuphine and other opioids or CNS depressants can be manifested by apnea, atypical snoring, bradycardia, cardiac arrest, circulatory depression or collapse, cold and clammy skin, constricted pupils, hypotension (severe), partial or complete airway obstruction, pulmonary edema, respiratory depression or arrest, skeletal muscle flaccidity, somnolence progressing to stupor or coma, and death.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. Naloxone hydrochloride will reverse severe cardiovascular, CNS, and respiratory reactions. Naloxone use should be reserved for situations in which clinically significant respiratory or circulatory depression is present. Titrate naloxone dose carefully to avoid precipitating an acute abstinence syndrome or uncontrolled pain. The duration of action of nalbuphine may exceed the duration of action of naloxone. Monitor patient carefully. Repeat doses of naloxone may be required. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment (e.g., fluids, vasopressors) must be instituted promptly. Resuscitate as necessary.

NALOXONE HYDROCHLORIDE

(nal-**OX**-ohn hy-droh-**KLOR**-eyed)
Antidote
Narcotic antagonist
pH 3 to 4

USUAL DOSE

Narcotic overdose:

0.4 to 2 mg. Repeat in 2 to 3 minutes if indicated. The diagnosis of narcotic overdose should be questioned if no response is observed after 10 mg of naloxone. If effective, dosage may be repeated as necessary for recurrence of symptoms.

Postoperative narcotic depression:

0.1 to 0.2 mg at 2- to 3-minute intervals to desired response. Titrate to avoid excessive reduction of narcotic analgesic action.

Challenge test for suspected opioid dependence:

0.2 mg. Observe for 30 seconds for S/S of withdrawal (e.g., abdominal cramps, diaphoresis, dysphoria, nausea and vomiting, rhinorrhea). If no evidence of withdrawal, inject 0.6 mg of naloxone and observe for an additional 20 minutes. Monitor VS and observe patient again for S/S of opiate withdrawal.

PEDIATRIC DOSE

Ampules containing 0.02 mg/mL are available, but larger doses are frequently required. Adult strength is often used to reduce amount of injection and to effect desired response, which may require increased or repeat doses. One source states, “Up to 10 times a dose has been required.”

Narcotic overdose:

Weight less than 20 kg:

0.01 to 0.1 mg/kg of body weight initially. Based on estimated degree of overdose and respiratory depression. May repeat every 2 to 3 minutes. May dilute with SWFI. American Academy of Pediatrics recommends 0.1 mg/kg. Manufacturer recommends 0.01 mg/kg.

Weight over 20 kg or over 5 years of age:

2 mg. Repeat every 2 to 3 minutes as needed. A continuous infusion may be used after initial effective dose. Add 75% to 100% of effective dose to a specific amount of IV fluid and infuse evenly distributed over 1 hour. For some overdoses (e.g., methadone), weaning in 50% increments may take up to 48 hours. For others, 6 to 12 hours is adequate. If symptoms recur, rebolus and go back to 100%.

Postoperative narcotic depression:

0.005 to 0.01 mg IV at 2- to 3-minute intervals to desired response.

NEONATAL DOSE

Neonatal opiate depression:

Administration into umbilical vein is preferred. 0.01 to 0.1 mg/kg of body weight initially. Based on estimated degree of overdose and respiratory depression. May repeat every 2 to 3 minutes to achieve a satisfactory response. May dilute with SWFI. American

Academy of Pediatrics recommends 0.1 mg/kg repeated every 2 to 3 minutes. Manufacturer recommends 0.01 mg/kg repeated every 2 to 3 minutes. Another source suggests an initial dose of 0.01 mg/kg. If response is not satisfactory, increase subsequent doses to 0.1 mg/kg.

DILUTION

May be given undiluted, diluted with SWFI, or further diluted in NS or D5W and given as an infusion (2 mg in 500 mL equals a concentration of 0.004 mg/mL). Discard infusions after 24 hours.

Storage:

Store below 40° C. Protect from light.

COMPATIBILITY

Manufacturer lists as **incompatible** with bisulfites, sulfites, long-chain or high-molecular-weight anions, solutions with an alkaline pH.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each 0.4 mg or fraction thereof over 30 seconds. Titrate infusion to patient response.

ACTIONS

A potent narcotic antagonist. Overcomes effects of narcotic overdose including respiratory depression, sedation, and hypotension. Unlike other narcotic antagonists, it does not have any narcotic effect itself. Onset of action is within 2 minutes. Duration of action is dependent on dose and route of naloxone administration. Requirement for repeat doses is dependent on amount, type, and route of narcotic administration. Metabolized in the liver and excreted in urine.

INDICATIONS AND USES

Reversal of narcotic depression. ■ Antidote for natural (e.g., morphine) and synthetic narcotics (e.g., butorphanol, methadone, nalbuphine, and pentazocine). ■ Diagnosis of suspected opioid tolerance or acute opiate overdose.

Unlabeled uses:

Reversal of alcoholic coma and improvement of circulation in refractory shock.

CONTRAINDICATIONS

Known hypersensitivity to naloxone. ■ The naloxone challenge test should not be performed in patients showing S/S of withdrawal or whose urine contains opioids.

PRECAUTIONS

Does not produce respiratory depression with nonnarcotic drug overdose, a beneficial action. ■ It is ineffective against respiratory depression caused by barbiturates, anesthetics, other nonnarcotic agents, or pathologic conditions. ■ Will precipitate acute withdrawal symptoms in narcotic addicts; use caution, especially in newborns of narcotic-dependent mothers. ■ Use caution in cardiac disease patients or those receiving cardiotoxic drugs.

Monitor:

Symptomatic treatment with oxygen and artificial ventilation as necessary should be continued until naloxone is effective. Observe patient continuously. Duration of narcotic action may exceed that of naloxone.

Maternal/Child:

Category B: use in pregnancy and breast-feeding only when clearly needed. Safety for use not established. ■ See Precautions.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Hypertension, irritability and increased crying in the newborn, nausea and vomiting, sweating, tachycardia, tremulousness. Overdose postoperatively may result in excitement, hypertension, hypotension, pulmonary edema, reversal of analgesia, ventricular tachycardia and fibrillation.

ANTIDOTE

Notify the physician of any side effect. Treatment will probably be symptomatic. Resuscitate as necessary.

NATALIZUMAB BBW

(nah-tah-**LIZZ**-u-mab)
Tysabri
Monoclonal antibody
Immunomodulator
pH 6.1

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Precautions and Monitor.

Multiple sclerosis (MS):

300 mg as an infusion every 4 weeks.

Crohn’s disease (CD):

300 mg as an infusion every 4 weeks. Discontinue if no benefit is seen after 12 weeks of therapy. For patients with CD who initiate natalizumab therapy while on chronic corticosteroids, begin steroid tapering as soon as therapeutic benefit of natalizumab has occurred. Discontinue natalizumab if the patient cannot be tapered off steroids within 6 months. Consider discontinuing therapy in patients who require more than 3 months of steroid use (excluding the original 6-month taper) in a calendar year to control their CD. Aminosalicylates may be continued during therapy with natalizumab.

DOSE ADJUSTMENTS

None indicated. Pharmacokinetics has not been studied in patients with renal or hepatic insufficiency.

DILUTION

Available in 300 mg/15 mL single-use vials. Solution is a colorless, clear to slightly opalescent concentrate. Do not use if particulates are present or if solution is discolored. Withdraw 15 mL of concentrate (300 mg) from the vial and inject into 100 mL of NS to prepare a solution with a final concentration of 2.6 mg/mL. Gently invert to mix completely. Do not shake. No other IV diluents may be used to prepare the solution.

Filters:

Use of filtration devices during administration not evaluated.

Storage:

Refrigerate vials at 2° to 8° C (36° to 46° F). Do not use beyond the expiration date on the vial. Do not shake or freeze. Protect from light. Following dilution, solution should be infused immediately. However, it may be refrigerated and used within 8 hours of preparation. If refrigerated, allow to warm to room temperature before infusion.

COMPATIBILITY

Manufacturer states, “Other medications should not be injected into infusion set side ports or mixed with natalizumab.” Flush line with NS before and after infusion.

RATE OF ADMINISTRATION

Do not administer as an IV push or bolus injection. Infuse over approximately 1 hour. Flush line with NS before and after infusion.

ACTIONS

A recombinant humanized IgG4κ monoclonal antibody produced in murine myeloma cells. An integrin receptor antagonist. Natalizumab is thought to bind to a subunit on the surface of all leukocytes except neutrophils and inhibit the adhesion of leukocytes to their counter-receptors. The receptors for the α4 family of integrin include vascular cell adhesion molecule-1 (VCAM-1), which is expressed on activated vascular endothelium, and mucosal addressin cell adhesion molecule-1 (MAdCAM-1), which is present on vascular endothelial cells of the GI tract. Disruption of these molecular interactions prevents transmigration of leukocytes across the endothelium into inflamed parenchymal tissue. Specific mechanisms of how natalizumab exerts its effects in MS and CD have not been fully defined. In multiple sclerosis (MS), lesions are believed to occur when activated inflammatory cells, including T-lymphocytes, cross the blood-brain barrier (BBB). Leukocyte migration across the BBB involves the interaction between adhesion molecules on inflammatory cells and their counter-receptors on the endothelial cells of the vessel wall. The clinical effect of natalizumab in MS may be secondary to blockade of the molecular interaction of α4β1 integrins expressed by inflammatory cells with VCAM-1 on vascular endothelial cells and with CS-1 and/or osteopontin expressed by parenchymal cells in the brain. In clinical trials, natalizumab reduced the rate of clinical relapse and the appearance of new or newly enlarging T2 hyperintense lesions on MRI studies. The number of gadolinium-enhancing lesions on the 1-year MRI scan follow-up was also reduced. In Crohn's disease (CD), the interaction of the α4β7 integrin with the endothelial receptor MAdCAM-1 has been implicated as an important contributor to the chronic inflammation seen in CD. MAdCAM-1 expression has been found to be increased at active sites of inflammation in the mucosa and to contribute to the inflammatory response characteristic of CD. It is mainly expressed on gut endothelial cells. The action of natalizumab may be secondary to blockade of molecular interaction of the α4β7-integrin receptor with MAdCAM-1 expressed on the venular endothelium at inflammatory foci. Distribution is limited primarily to vascular space (plasma volume). Half-life is 3 to 17 days.

INDICATIONS AND USES

Monotherapy for the treatment of relapsing forms of multiple sclerosis (MS), including clinically isolated syndrome, relapsing-remitting disease, and active secondary progressive disease, in adults. ■ Induction and maintenance of clinical response and remission in adults with moderately to severely active Crohn's disease with evidence of inflammation who have had an inadequate response to or are unable to tolerate conventional therapy and inhibitors of TNFα (e.g., infliximab). Should not be used in combination with immunosuppressants (e.g., 6-mercaptopurine, azathioprine, cyclosporine, or methotrexate) or inhibitors of TNFα; see Precautions.

CONTRAINDICATIONS

Hypersensitivity to natalizumab or any of its components. ■ Patients who have or have had progressive multifocal leukoencephalopathy (PML).

PRECAUTIONS

Natalizumab increases the risk of progressive multifocal leukoencephalopathy (PML), a rare opportunistic viral infection of the brain caused by the JC virus (JCV) that usually leads to death or severe disability. PML typically occurs only in patients who are immunocompromised. Risk factors for the development of PML include duration of therapy (especially beyond 2 years), prior use of immunosuppressants (e.g., azathioprine, cyclophosphamide, methotrexate, mitoxantrone, or mycophenolate), and the presence of anti-JCV antibodies. Patients who are anti–JCV antibody positive have a higher risk of developing PML. These factors should be considered in the context of expected benefits when initiating and continuing treatment with natalizumab. ■ There are no known interventions that can reliably prevent PML or adequately treat PML if it occurs. Because of the risk of PML, natalizumab is available only through a special restricted distribution program called the TOUCH™ Prescribing Program. See prescribing information, or contact the manufacturer for specific details and requirements. Retrospective analyses of post-marketing data suggest that the risk of developing PML may be associated with relative levels of serum anti-JCV antibody compared to a calibrator as measured by ELISA (often described as an anti-JCV antibody index value). ■ Infection by the JC virus is required for the development of PML. ■ Anti-JCV antibody testing should not be used to diagnose PML. Testing positive for anti-JCV antibodies means that a person has been exposed to JCV in the past. Consider testing patients before treatment or during treatment if antibody status is unknown. Patients who test negative for anti-JCV antibodies have a lower risk of PML but are still at risk for the development of PML because of the potential for a new JCV infection or a false-negative test result. Periodic retesting of antibody status should be considered in patients previously determined to be anti–JCV antibody negative. Anti–JCV testing should not be performed for at least 2 weeks after plasma exchange due to the removal of antibodies from the serum. After an IVIG infusion, wait at least 6 months for the IVIG to clear to avoid a false-positive anti-JCV antibody test result. ■ PML has been reported after discontinuation of natalizumab in patients who did not have findings suggestive of PML at the time of discontinuation. Patients should continue to be monitored for any new S/S suggestive of PML for at least 6 months after discontinuing natalizumab. ■ JC virus infection of granule cell neurons in the cerebellum (i.e., JC virus granule cell neuronopathy [JCV GCN]) has been reported and can cause cerebellar dysfunction (e.g., apraxia, ataxia, incoordination, visual disorders). ■ Patients who develop PML and have discontinued natalizumab have developed immune reconstitution inflammatory syndrome (IRIS). In most cases IRIS occurred after plasma exchange was used to eliminate circulating natalizumab. This syndrome has not been seen in patients discontinuing treatment for reasons unrelated to PML. ■ Has been associated with hypersensitivity reactions, including anaphylaxis. Reactions usually occur within 2 hours of the start of the infusion. Generally associated with antibodies to natalizumab. ■ In studies, persistent antibody positivity resulted in a substantial decrease in the effectiveness of natalizumab and an increased incidence of hypersensitivity/infusion-related reactions. Patients who receive natalizumab for a short exposure (1 to 2 infusions) followed by an extended period without treatment are at higher risk for developing anti-natalizumab antibodies and/or hypersensitivity reactions on re-exposure compared with patients who received regularly scheduled treatments. Given that patients with persistent antibodies to natalizumab experience reduced efficacy and that hypersensitivity reactions are more common in such patients, consideration should be given to testing for the presence of antibodies in patients who want to resume therapy after a dose interruption. ■ Effects on immune system may increase the risk of infection, including opportunistic infection. ■ Risk for developing encephalitis and meningitis caused by herpes simplex and varicella zoster viruses is increased. Serious, life-threatening, and sometimes fatal cases have been reported. ■ Acute retinal necrosis (ARN), a fulminant viral infection of the retina caused by the family of herpes viruses (e.g., varicella zoster, herpes simplex virus), has been reported.

May lead to blindness. ■ Liver injury has been reported; it has occurred as early as 6 days after the first dose and after multiple doses. The combination of ALT, AST, and bilirubin elevations without evidence of obstruction is generally recognized as an important predictor of severe liver injury that may lead to death or the need for liver transplantation. ■ No data available on secondary transmission of infections by live virus vaccines.

Monitor:

Obtain baseline CBC and differential. Monitor periodically during treatment. Increases in circulating lymphocytes, monocytes, eosinophils, basophils, and nucleated red blood cells and mild decreases in hemoglobin levels have been observed. ■ Obtain a baseline MRI before initiating treatment and periodically throughout treatment. In MS patients it may be helpful in differentiating subsequent MS symptoms from PML and assessing disease progression. In CD patients it may be helpful in distinguishing pre-existing lesions from newly developed lesions. Cases of PML have been reported that were diagnosed based on MRI findings and on the detection of JCV DNA in the CSF in the absence of clinical S/S specific to PML (i.e., MRI findings may be apparent before clinical S/S of PML). Periodic monitoring for radiographic signs consistent with PML should be considered to allow for an early diagnosis of PML. Lower PML-related mortality and morbidity have been reported following natalizumab discontinuation in patients with PML who were initially asymptomatic compared with patients with PML who had characteristic clinical S/S at diagnosis. It is not known whether these differences are due to early detection and discontinuation of natalizumab or due to differences in disease in these patients. ■ Consider determining anti-JCV antibody status before initiating natalizumab. Reassess status periodically; see Precautions. ■ Observe patients during the infusion and for 1 hour after the infusion is complete. Discontinue infusion at the first sign of any hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Anti-natalizumab antibodies detected within the first 6 months of therapy may be transient and disappear. Repeat testing in 3 months. If antibodies are persistent, consider risk versus benefit of continued therapy; see Precautions. ■ Assess neurologic status frequently for S/S of PML and JCV GCN. S/S associated with PML are diverse and occur over days to weeks. May include progressive weakness on one side of the body, clumsiness of limbs, disturbances of vision, or changes in thinking, memory, and orientation leading to confusion and personality changes. Progression of deficits usually leads to severe disability or death over weeks to months. Withhold natalizumab if PML is suspected. ■ Use of a gadolinium-enhanced MRI scan of the brain is recommended for diagnosis of PML and JCV GCN. When indicated, CSF analysis for JC viral DNA may also be used to aid in diagnosis. If clinical suspicion of PML remains after initial evaluations are negative, continue to withhold natalizumab, and repeat evaluations. Continue to monitor for S/S suggestive of PML for approximately 6 months after discontinuation of natalizumab. ■ Monitor for S/S of IRIS; may occur within days to weeks after plasma exchange. IRIS presents as a clinical decline in condition (may occur after clinical improvement); decline may be rapid, can lead to serious neurologic complications or death, and is often associated with characteristic changes in the MRI. ■ Monitor for S/S of infection. ■ Monitor for S/S of meningitis and encephalitis (e.g., confusion, fever, headache). ■ Monitor for S/S of ARN (e.g., decreased visual acuity, eye pain, redness). Patients presenting with eye symptoms should be referred for retinal screening. ■ Monitor for S/S of liver injury (e.g., elevated bilirubin or liver function tests, jaundice). ■ Monitor for signs of clinical relapse.

Patient Education:

Read medication guide carefully. ■ Review medical conditions and medications with health care provider. ■ Promptly report any new medical problems (e.g., new or sudden change in thinking, eyesight, balance, or strength). ■ Report infections. ■ Promptly report S/S of encephalitis and meningitis (e.g., confusion, fever, headache) or acute retinal necrosis (e.g., decreased visual acuity, eye pain, or redness). ■ Promptly report S/S of hepatotoxicity (e.g., anorexia, dark urine, fatigue, jaundice, right upper abdominal discomfort), meningitis, or encephalitis (e.g., confusion, fever, headache). ■ Immediately report any symptoms of infusion or hypersensitivity reactions (e.g., difficulty breathing, dizziness, feeling faint, itching, nausea). ■ Discuss potential risks and benefits of treatment (e.g., risk of PML). ■ Your physician may order a blood test to see if you have ever been exposed to JCV. Risk of PML is greatest if you have all three known risk factors; see Precautions. ■ Scheduled follow-up visits are required as part of the TOUCH™ Program. ■ PML has been reported following discontinuation of natalizumab. Monitor for S/S suggestive of PML for approximately 6 months after discontinuation of therapy.

Maternal/Child:

Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ Has been detected in breast milk. Risk of this exposure to infant is unknown. ■ Safety and effectiveness for use in pediatric patients with MS or CD under 18 years of age not established.

Elderly:

Studies did not include sufficient numbers of patients 65 years of age and older to determine whether they respond differently than younger patients. Differences have not been identified in clinical practice.

DRUG/LAB INTERACTIONS

Formal studies not completed. Concurrent use with **antineoplastic, immunosuppressant, or immunomodulating agents** may further increase the risk of infection, including PML and other opportunistic infections, over the risk observed with the use of natalizumab alone. Safety and efficacy of natalizumab in combination with any of these agents not established. ■ Concurrent use of short courses of **corticosteroids** was associated with an increase in infections in clinical trials. Corticosteroids should be tapered in patients with CD who are initiating natalizumab therapy; see Usual Dose. ■ No data are available on the effects of **vaccination** in patients receiving natalizumab. ■ Increases circulating **lymphocytes, monocytes, eosinophils, basophils, and nucleated red blood cells.** A return to baseline usually occurs within 16 weeks after the last dose. Elevations of **neutrophils** are not observed. ■ May induce mild decreases in **hemoglobin,** frequently transient.

SIDE EFFECTS

The most commonly reported adverse reactions were abdominal discomfort, arthralgia, depression, diarrhea, fatigue, gastroenteritis, headache, infections (UTI, upper and lower respiratory tract), nausea, pain in extremities, rash, and vaginitis. The most commonly reported serious adverse reactions were infections, hypersensitivity reactions (including anaphylaxis), depression (including suicidal ideation), and cholelithiasis. The most commonly reported adverse reactions resulting in clinical intervention (i.e., discontinuation of natalizumab) were urticaria and other hypersensitivity reactions. Infusion-related reactions (defined as any adverse event occurring within 2 hours of the start of an infusion) included headache, dizziness, fatigue, hypersensitivity reactions, nausea, pruritus, rigors, urticaria, and vomiting. Other reported adverse reactions included abnormal liver function tests, amenorrhea, antibody formation, aphthous stomatitis, back pain, chest discomfort, constipation, cough, dermatitis, dry skin, dyspepsia, flatulence, infections (including bacterial, viral, and opportunistic), influenza-like illness, irregular menstruation/dysmenorrhea, joint swelling, local bleeding, muscle cramps, night sweats, peripheral edema, pharyngolaryngeal pain, pruritus, somnolence, syncope, tonsillitis, tremor, urinary urgency, frequency and incontinence, and vertigo. Adverse reactions reported in persistently antibody-positive patients included anxiety, dyspnea, hypertension, infusion-related/hypersensitivity reactions, myalgia, and tachycardia.

Post-Marketing:

Acute retinal necrosis (ARN), eosinophilia (resolved with discontinuation of therapy), hemolytic anemia, herpes simplex virus encephalitis and meningitis, herpes zoster virus meningitis, JC virus granule cell neuronopathy (JCV GCN), PML in patients treated with natalizumab monotherapy.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically. Consider discontinuation of natalizumab in patients who are diagnosed with ARN. Treatment for ARN may include antiviral therapy and surgery. Discontinue natalizumab at the first sign of liver injury, S/S of meningitis or encephalitis, S/S suggestive of PML, or with any change in neurologic status. Discontinue infusion if any S/S of a hypersensitivity or infusion reaction occur. Treat with epinephrine, corticosteroids, diphenhydramine, bronchodilators, and oxygen as indicated. Patients who experience a hypersensitivity reaction should not be retreated with natalizumab.

NECITUMUMAB BBW

(neh-**CIT**-ue-mew-mab)
Portrazza
Antineoplastic
(Monoclonal antibody, epidermal growth factor receptor [EGFR] inhibitor)
pH 6

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies required; see Monitor.

Premedication:

For patients who have experienced a previous Grade 1 or 2 infusion-related reaction (IRR), premedicate with diphenhydramine or equivalent before all subsequent necitumumab infusions. For patients who have experienced a second occurrence of Grade 1 or 2 IRR, premedicate before all subsequent necitumumab infusions with diphenhydramine (or equivalent), acetaminophen (or equivalent), and dexamethasone (or equivalent).

Necitumumab:

800 mg as an IV infusion over 60 minutes on Days 1 and 8 of each 3-week cycle. Administer before gemcitabine (Gemzar) and cisplatin infusions. Continue until disease progression or unacceptable toxicity. Refer to gemcitabine and cisplatin monographs for premedication, hydration, dose recommendations, precautions, monitoring, and other requirements before administration.

DOSE ADJUSTMENTS

Reduce the infusion rate of necitumumab by 50% for a Grade 1 IRR. ■ Stop the infusion for a Grade 2 IRR. When signs and symptoms have resolved to Grade 0 or 1, resume necitumumab at a 50% reduced rate for all subsequent infusions. ■ Permanently discontinue necitumumab for a Grade 3 or 4 IRR. ■ Withhold necitumumab for Grade 3 dermatologic toxicity (e.g., rash or acneiform rash) until symptoms resolve to Grade 2 or less, then resume necitumumab at a reduced dose of 400 mg for at least 1 treatment cycle. If symptoms do not worsen, dose may be increased to 600 mg and 800 mg in subsequent cycles. ■ Permanently discontinue necitumumab for dermatologic toxicity if (1) the Grade 3 rash or acneiform rash does not resolve to Grade 2 or less within 6 weeks, (2) reactions worsen or become intolerable at a dose of 400 mg, (3) patient experiences a Grade 3 skin induration/fibrosis, or (4) patient experiences Grade 4 dermatologic toxicity. ■ Withhold necitumumab for Grade 3 or 4 electrolyte abnormalities. Administer subsequent cycles once electrolyte abnormalities have improved to Grade 2 or less. ■ No dose adjustment necessary based on body weight.

DILUTION

Available as a preservative-free solution in a single-dose vial containing 800 mg/50 mL (16 mg/mL). Solution should be clear. Discard if discolored or particulate matter is present. Withdraw the desired dose and further dilute to a final volume of 250 mL with NS. Do not use solutions containing dextrose. Gently invert the container to ensure adequate mixing. ***Do not freeze or shake.***

Filters:

Specific information not available.

Storage:

Before use, refrigerate at 2° to 8° C (36° to 46° F) in original carton to protect from light. ***Do not freeze or shake the vial***. Diluted solution may be stored for no more than 24 hours if refrigerated or no more than 4 hours at RT. Discard any unused portion left in the vial.

COMPATIBILITY

Manufacturer states, "Do not dilute with solutions other than NS or co-infuse with other electrolytes or medication." Use of a separate line required.

RATE OF ADMINISTRATION

Administer as an infusion over 60 minutes using an infusion pump through a separate infusion line. Flush the line with NS at the end of the infusion. Reduce rate or discontinue infusion for IRR; see Dose Adjustments.

ACTIONS

A recombinant human IgG1 monoclonal antibody that specifically binds to the human epidermal growth factor receptor (EGFR) and blocks the binding of EGFR to its ligands. Expression and activation of EGFR have been correlated with malignant progression, induction of angiogenesis, and inhibition of apoptosis. Binding of necitumumab induces EGFR internalization and degradation in vitro and also leads to antibody-dependent cellular cytotoxicity in EGFR-expressing cells. Elimination half-life is approximately 14 days. The predicted time to reach steady state is approximately 100 days.

INDICATIONS AND USES

First-line treatment of patients with metastatic squamous non–small-cell lung cancer in combination with gemcitabine and cisplatin.

Limitation of use:

Not indicated for treatment of nonsquamous non–small-cell lung cancer. These patients experienced more serious and fatal toxicities, including cardiopulmonary arrest/sudden death, within 30 days when administered necitumumab in combination with pemetrexed and cisplatin.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Administered by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Cardiopulmonary arrest and/or sudden death has been reported with necitumumab used in combination with gemcitabine and cisplatin. Some of these deaths occurred within 30 days of the last dose of necitumumab in patients with comorbid conditions, including a history of coronary artery disease, hypomagnesemia, COPD, and/or hypertension. ■ Hypomagnesemia occurred in most patients receiving necitumumab in combination with gemcitabine and cisplatin and was severe in 20% of patients. The median time to development of hypomagnesemia and accompanying electrolyte abnormalities was 6 weeks after initiation of necitumumab. ■ Venous and arterial thromboembolic events (VTEs and ATEs), some fatal, have been observed. The most common VTEs were pulmonary embolism and deep vein thrombosis. The most common ATEs were cerebral stroke and ischemia and myocardial infarction. Risk is higher in patients with a reported history of VTEs or ATEs. ■ Dermatologic toxicities, some severe, have been reported. ■ Infusion-related reactions have been reported. Most IRRs occurred after the first or second administration of necitumumab; see Premedication and Monitor. ■ As with all therapeutic proteins, there is a potential for immunogenicity. ■ Renal function and mild to moderate hepatic impairment have no influence on the exposure to necitumumab based on population pharmacokinetic analysis; however, no formal studies have been conducted. No patients with severe hepatic impairment were enrolled in clinical trials.

Monitor:

Obtain serum electrolytes (including serum magnesium, potassium, and calcium), before each dose of necitumumab. Closely monitor for hypomagnesemia, hypocalcemia, and hypokalemia during treatment and for at least 8 weeks after the last dose is administered, with aggressive replacement when warranted during and after administration of necitumumab. ■ Withhold necitumumab for Grade 3 or 4 electrolyte abnormalities. ■ Monitor for S/S of venous and arterial thromboembolic events (e.g., chest pain, limb or abdominal swelling and/or pain, shortness of breath, loss of sensation or motor power, or altered consciousness, vision, or speech). ■ Monitor for dermatologic toxicities (e.g., acne, dermatitis acneiform, dry skin, erythema, generalized rash, maculopapular rash, rash, skin fissures). Usually develops within the first 2 weeks of therapy and resolves within 17 weeks after onset; see Dose Adjustments and Antidote. ■ Monitor for S/S of IRRs (e.g., chills, dyspnea, fever, hypotension, rash, tightness of the chest, urticaria, wheezing) during and after infusion; see Dose Adjustments and Antidote.

Patient Education:

Blood levels of magnesium, potassium, and calcium may be decreased. Take medicines to replace these electrolytes exactly as advised by the physician. ■ Risk of venous and arterial thromboembolic events is increased. Promptly report chest pain, limb or abdominal swelling and/or pain, shortness of breath, loss of sensation or motor power, or altered consciousness, vision, or speech. ■ To reduce the risk of dermatologic reactions, minimize sun exposure with the use of protective clothing and sunscreen during treatment. ■ Immediately report S/S of an infusion-related reaction (e.g., breathing problems, chills, fever, rash, tightness of the chest, urticaria, wheezing). ■ There is a potential risk to a fetus and to postnatal development. Effective contraception is required in females of reproductive potential during treatment and for 3 months after the final dose. ■ See Maternal/Child.

Maternal/Child:

Based on its mechanism of action, necitumumab can cause fetal harm or developmental anomalies. Effective contraception required; see Patient Education. ■ Discontinue breast-feeding during treatment and for 3 months after the final dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

There was a higher incidence of venous thromboembolic events, including pulmonary embolism, in patients age 70 years and over compared with younger patients.

DRUG/LAB INTERACTIONS

When used in combination with gemcitabine, the dose-normalized area under the curve (AUC) of gemcitabine was increased. Exposure to cisplatin was unchanged. Gemcitabine and cisplatin had no effect on the exposure of necitumumab.

SIDE EFFECTS

The most common adverse reactions (all grades) observed more frequently in patients treated with necitumumab than with gemcitabine and cisplatin alone were dermatitis acneiform, diarrhea, hypomagnesemia, rash, and vomiting. The most common severe (Grade 3 or higher) adverse events were thromboembolic events (including pulmonary embolism), rash, and vomiting. Acne, conjunctivitis, dry skin, electrolyte abnormalities (including hypocalcemia, hypokalemia, and hypophosphatemia), headache, hemoptysis, paronychia, pruritus, skin fissures, stomatitis, VTE, and weight decrease have been reported.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Reduce the infusion rate of necitumumab by 50% for Grade 1 IRRs. Stop the infusion for Grade 2 IRRs. Treat infusion-related reactions as indicated and provide premedication (e.g., diphenhydramine, acetaminophen, corticosteroids) for subsequent infusions; see Usual Dose. When signs and symptoms have resolved to Grade 0 or 1, resume necitumumab at a 50% reduced rate for all subsequent infusions. Withhold necitumumab for Grade 3 or 4 electrolyte abnormalities. Permanently discontinue necitumumab for any of the following: (1) Grade 3 or 4 IRR, (2) Grade 3 rash or acneiform rash that does not resolve to Grade 2 or less within 6 weeks, (3) dermatologic reactions that worsen or become intolerable at a dose of 400 mg, (4) Grade 3 skin induration/fibrosis, or (5) Grade 4 dermatologic toxicity. See Dose Adjustments, Precautions, and Monitor.

NELARABINE BBW

(nell-ah-**RA**-ben)
Arranon
Antineoplastic
pH 5 to 7

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies required; see Monitor.

Nelarabine:

1,500 mg/M^2 administered as an infusion over 2 hours on Days 1, 3, and 5. Repeat every 21 days. The recommended duration of treatment has not been clearly established. In clinical trials, treatment was generally continued until there was evidence of disease progression or until the patient experienced unacceptable toxicity, became a candidate for hematopoietic stem cell transplantation (HSCT), or no longer continued to benefit from treatment.

PEDIATRIC DOSE

650 mg/M^2 administered as an infusion over 1 hour daily for 5 consecutive days. Repeat every 21 days; see Usual Dose.

DOSE ADJUSTMENTS

Discontinue therapy for neurologic events of Common Terminology Criteria for Adverse Events (CTCAE) Grade 2 or greater. Dosage may be delayed for other toxicity, including hematologic toxicity. ■ Has not been studied in patients with hepatic or renal impairment. Because nelarabine and ara-G are partially eliminated by the kidneys, clearance may be reduced in patients with renal insufficiency. No dose adjustment is recommended for patients with a CrCl equal to or greater than 50 mL/min. Dose recommendations are not available for patients with a CrCl less than 50 mL/min; see Precautions. ■ Use caution in dose selection for the elderly.

DILUTION

Specific techniques required; see Precautions.

Nelarabine is not diluted before administration. Available in a 250 mg/50 mL (5 mg/mL) single-dose vial. Transfer the appropriate dose into a polyvinylchloride (PVC) infusion bag or glass container and administer as an infusion. Example: An adult patient with a body surface area of 2 M^2 would require a dose of 3,000 mg (1,500 mg/M^2 × 2 M^2 = 3,000 mg). 3,000 mg ÷ 250 mg/vial = 12 vials.

Filters:

Specific information not available.

Storage:

Store unopened vials at CRT. Stable in PVC infusion bags or glass containers for up to 8 hours at up to 30° C (86° F).

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Adult dose:

A single dose evenly distributed over 2 hours.

Pediatric dose:

A single dose evenly distributed over 1 hour.

ACTIONS

A prodrug of ara-G, a T-cell selective nucleoside metabolic inhibitor. Nelarabine is demethylated to ara-G and then converted through various metabolic processes to the active 5′-triphosphate, ara-GTP. Ara-GTP is incorporated into DNA, leading to inhibition of DNA synthesis and cell death. Nelarabine and ara-G are extensively distributed throughout the body and are rapidly eliminated from the plasma, with a mean half-life of 18 minutes and 3.2 hours, respectively. They are partially eliminated by the kidneys.

INDICATIONS AND USES

Treatment of T-cell acute lymphoblastic leukemia (T-ALL) and T-cell lymphoblastic lymphoma (T-LBL) in adult and pediatric patients 1 year of age and older whose disease has not responded to treatment or has relapsed following treatment with at least two chemotherapy regimens.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ For IV use only. ■ Administered by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Neurotoxicity is the dose-limiting toxicity. Severe neurologic events have been reported and may include altered mental states including severe somnolence, central nervous system effects including convulsions, and peripheral neuropathy ranging from numbness and paresthesias to motor weakness and paralysis. Events associated with demyelination and ascending peripheral neuropathies similar in appearance to Guillain-Barré syndrome have also been reported. Full recovery from these events has not always occurred with cessation of therapy. ■ Patients treated previously or concurrently with intrathecal chemotherapy or previously with craniospinal irradiation may be at increased risk for neurologic adverse events. ■ Hematologic toxicity (e.g., anemia, leukopenia, neutropenia [including febrile neutropenia], thrombocytopenia) is common. ■ Use caution in patients with renal or hepatic impairment. Use has not been studied. Patients with a CrCl less than 50 mL/min or a bilirubin greater than 3 times the ULN may be at increased risk for toxicity. Monitor closely. ■ May develop tumor lysis syndrome. ■ See Drug/Lab Interactions.

Monitor:

Obtain a baseline CBC with platelets and monitor regularly. ■ Monitor renal and hepatic function (BUN, SCr, bilirubin). ■ Monitor frequently for S/S of neurologic toxicity during treatment and for at least 24 hours after completion of treatment. Common S/S of nelarabine-related neurotoxicity include cerebellar disturbances, dizziness, dysesthesia, headache, neuropathy (motor and sensory), paresthesia, somnolence, and tremor. Severe neurologic toxicity can manifest as coma, status epilepticus, craniospinal demyelination, or ascending neuropathy similar in presentation to Guillain-Barré syndrome; see Precautions and Antidote. ■ Monitor for S/S of tumor lysis syndrome (e.g., hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure). ■ Prevention and treatment of hyperuricemia due to TLS may be accomplished with adequate hydration and, if necessary, with uric acid–lowering drugs (e.g., allopurinol). ■ Monitor for S/S of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Avoid administration of live virus vaccines to immunocompromised patients.

Patient Education:

Read manufacturer's patient information. ■ Avoid pregnancy. ■ Females of reproductive potential should use effective contraception during treatment. Males (including those who have had vasectomies) with female partners of reproductive potential should use condoms during treatment and for 3 months after the last dose. ■ Use caution in tasks that require alertness. Refrain from driving or engaging in hazardous occupations or activities until somnolence has resolved. ■ Notify physician at first sign of infection or of new or worsening neurotoxicity (e.g., numbness, tingling, difficulty with fine motor coordination, unsteadiness, weakness, seizures). ■ Blood counts will be monitored regularly during treatment. ■ Do not receive live vaccines during treatment.

Maternal/Child:

Avoid pregnancy; may cause fetal harm. ■ Discontinue breast-feeding. ■ The safety and effectiveness of nelarabine for relapsed or refractory T-ALL and T-LBL has not been established in pediatric patients 1 year and older. ■ The mean clearance of nelarabine is about 30% higher in pediatric patients than in adult patients. Half-lives of nelarabine and ara-G are shorter than those seen in adults—13 minutes and 2 hours, respectively.

Elderly:

May be at increased risk of neurologic adverse events. Clearance may be reduced in the elderly due to age-related renal impairment; see Dose Adjustments and Precautions.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been completed. ■ Concurrent administration with **adenosine deaminase inhibitors** (e.g., pentostatin) is not recommended; may decrease conversion of nelarabine to its active form and decrease its effectiveness. ■ Nelarabine and ara-G do not appear to inhibit the activities of human hepatic cytochrome P_{450} isoenzymes. ■ Fludarabine does not appear to affect the pharmacokinetics of nelarabine, ara-G, or ara-GTP. ■ Do not administer **live virus vaccines** to immunocompromised patients receiving antineoplastic agents.

SIDE EFFECTS

Adults:

Side effects most frequently reported were anemia, constipation, cough, diarrhea, dizziness, dyspnea, fatigue, fever, headache, hyperuricemia, hypoesthesia, nausea, neutropenia, paresthesia, peripheral neurologic disorders, somnolence, thrombocytopenia, and vomiting. Other reported side effects included abdominal distension, abdominal pain, abnormal gait, anorexia, arthralgia, asthenia, back pain, blurred vision, chest pain, chills, confusion, dehydration, depression, edema, epistaxis, exertional dyspnea, extremity pain, febrile neutropenia, hyperglycemia, hypotension, increased AST, infection, insomnia, muscular weakness, myalgia, noncardiac chest pain, pain, peripheral edema, petechiae, pleural effusion, pneumonia, sinusitis, sinus tachycardia, stomatitis, and wheezing. ***Neurologic*** side effects in adults were mostly Grade 1 or 2 and included amnesia, ataxia, balance disorder, depressed level of consciousness, headache, hypoesthesia, neuropathy (peripheral, peripheral motor, and peripheral sensory), paresthesia, sensory loss, taste alteration, and tremor. Grade 3 events included aphasia, convulsion, hemiparesis, and loss of consciousness. Cerebral hemorrhage, coma, intracranial hemorrhage, leukoencephalopathy, and metabolic encephalopathy also were reported. One patient had a cerebral hemorrhage (fatal), coma, and leukoencephalopathy.

Pediatric patients:

Side effects most frequently reported were anemia, decreased blood albumin and potassium levels, headache, increased bilirubin, increased transaminase levels, leukopenia, neutropenia, peripheral neurologic disorders, thrombocytopenia, and vomiting. Other reported side effects included asthenia; decreased calcium, glucose, and magnesium levels; increased SCr; and infection. ***Neurologic*** side effects that were greater than Grade 2 included ataxia, headache, hypertonia, hypoesthesia, motor dysfunction, neuropathy (peripheral, peripheral motor, and peripheral sensory), paralysis of the third and sixth nerves, paresthesia, seizures (convulsions, grand mal convulsions, status epilepticus), somnolence, tremor.

Overdose:

Myelosuppression, severe neurotoxicity (coma, paralysis), and potentially death.

Post-Marketing:

Demyelination and ascending peripheral neuropathies similar in appearance to Guillain-Barré syndrome, increased blood creatine phosphokinase, opportunistic infections (fatal), rhabdomyolysis, tumor lysis syndrome.

ANTIDOTE

Notify physician of any side effects. Most will be treated symptomatically. Discontinue therapy for neurologic events of Common Terminology Criteria for Adverse Events (CTCAE) Grade 2 or greater. Dosage may be delayed for other toxicity, including hematologic toxicity. Blood and blood products, antibiotics, and other adjunctive therapies must be available. Blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. No known antidote; provide supportive care in overdose. Resuscitate as necessary.

NEOSTIGMINE METHYLSULFATE

(nee-oh-**STIG**-meen **METH**-ill-**SUL**-fayt)
Bloxiverz
Acetylcholinesterase inhibitor
pH 5.5

USUAL DOSE

Pretreatment:

Doses should be individualized. A peripheral nerve stimulator should be used to determine when neostigmine should be initiated and if additional doses are needed. Before neostigmine administration and up until complete recovery of normal ventilation, the patient should be well ventilated and a patent airway maintained. An anticholinergic agent (e.g., atropine or glycopyrrolate) should be administered before or concomitantly with neostigmine using a separate syringe.

Atropine:

0.6 to 1.2 mg IV for each 0.5 to 2 mg of neostigmine **OR**

Glycopyrrolate:

0.2 mg IV for each 1 mg of neostigmine; see Precautions.

Neostigmine:

0.03 to 0.07 mg/kg. This dose will generally achieve a train-of-four (TOF) twitch ratio of 90% within 10 to 20 minutes of administration. The recommended maximum total dose is 0.07 mg/kg or up to a total of 5 mg, whichever is less. Dose selection should be based on the extent of spontaneous recovery that has occurred at the time of administration, the half-life of the neuromuscular blocking agent (NMBA) being reversed, and whether there is a need to rapidly reverse the NMBA.

The 0.03 mg/kg dose is recommended for:

- Reversal of NMBAs with shorter half-lives (e.g., rocuronium) **OR**
- When the first twitch response to the train-of-four (TOF) stimulus is substantially greater than 10% of baseline or when a second twitch is present.

The 0.07 mg/kg dose is recommended for:

- Reversal of NMBAs with longer half-lives (e.g., pancuronium or vecuronium) **OR**
- When the first twitch response is relatively weak (i.e., not substantially greater than 10% of baseline) **OR**
- There is need for more rapid recovery.

PEDIATRIC DOSE

See Usual Dose and Maternal/Child.

DOSE ADJUSTMENTS

Individualize dose based on extent of spontaneous recovery at time of administration, the half-life of the NMBA being reversed, and whether or not there is a need to rapidly reverse the NMBA. ■ Use with caution and with minimum effective dose in pediatric patients and in patients with coronary artery disease, cardiac arrhythmias, recent acute coronary syndrome, or myasthenia gravis; see Maternal/Child. ■ Reduce dose if recovery from neuromuscular blockade is nearly complete. See Precautions and Monitor.

DILUTION

Available in 0.5 mg/mL and 1 mg/mL in 10-mL multiple-dose vials. May be given undiluted through Y-tube or three-way stopcock of infusion set.

Storage:

Store at CRT in carton. Protect from light.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Inject slowly over a period of at least 1 minute.

ACTIONS

A competitive cholinesterase inhibitor and antagonist of nondepolarizing neuromuscular blocking agents. Inhibits the enzyme cholinesterase. By reducing the breakdown of acetylcholine, neostigmine induces an increase in acetylcholine in the synaptic cleft. Acetylcholine competes for the same binding sites as nondepolarizing NMBAs and reverses the neuromuscular blockade. The increase in acetylcholine levels results in the potentiation of both muscarinic and nicotine cholinergic activity. Does not cross the blood-brain barrier so does not significantly affect cholinergic function in the CNS. Metabolized by microsomal enzymes in the liver. Half-life ranges from 24 to 113 minutes. Excreted primarily in urine.

INDICATIONS AND USES

Reversal of the effects of nondepolarizing neuromuscular blocking agents after surgery.

Unlabeled use:

Treatment of myasthenia gravis.

CONTRAINDICATIONS

Known hypersensitivity to neostigmine (known hypersensitivity reactions have included urticaria, angioedema, erythema multiforme, generalized rash, facial swelling, peripheral edema, fever, flushing, hypotension, bronchospasm, bradycardia, and anaphylaxis). ■ Peritonitis or mechanical obstruction of the intestinal or urinary tract.

PRECAUTIONS

For IV administration only. ■ Should be administered by a trained health care provider familiar with the use, actions, characteristics, and complications of neuromuscular blocking agents and neuromuscular block reversal agents. ■ Neostigmine has been associated with bradycardia. In the presence of bradycardia, it is recommended that the anticholinergic agent (atropine or glycopyrrolate) be administered before neostigmine. ■ Cardiovascular effects such as bradycardia, hypotension, or dysrhythmia are anticipated with acetylcholinesterase inhibitors such as neostigmine. Use with caution in patients with coronary artery disease, cardiac arrhythmias, recent acute coronary syndrome, or myasthenia gravis. Risk of blood pressure and heart rate complications may be increased in these patients. ■ Because of the possibility of hypersensitivity, atropine and medications to treat anaphylaxis should be readily available. ■ Large doses of neostigmine administered when neuromuscular blockade is minimal can produce neuromuscular dysfunction. The dose of neostigmine should be reduced if recovery from neuromuscular blockade is nearly complete. ■ It is important to distinguish between myasthenic crisis and cholinergic crisis caused by overdose of neostigmine. Both result in extreme muscle weakness but require radically different treatment; see Antidote. ■ Use with caution in patients with renal and hepatic impairment. Dose adjustment is not required, but duration of action of NMBAs that are renally or hepatically eliminated may be prolonged. Patients must be carefully monitored to ensure that the effects of the NMBA do not persist beyond those of neostigmine.

Monitor:

A peripheral nerve stimulation device capable of delivering a train-of-four (TOF) stimulus is required. There must be a twitch response to the first stimulus in the TOF of at least 10% of its baseline level (i.e., the response prior to the NMBA) before administering neostigmine. ■ TOF monitoring alone should not be relied on to determine the adequacy of reversal of neuromuscular blockade as related to a patient's ability to adequately ventilate and maintain a patent airway following tracheal extubation. Satisfactory recovery should be judged by adequacy of skeletal muscle tone and respiratory measurements in addition to the response to the peripheral nerve stimulator. ■ Continue monitoring for adequacy of reversal for a period that will ensure full recovery based on the patient's medical condition and the pharmacokinetics of neostigmine and the NMBA used.

Maternal/Child:

It is not known whether neostigmine can cause fetal harm when administered to a pregnant woman; use during pregnancy, labor, or delivery only if clearly needed. Acetylcholinesterase drugs, including neostigmine, may cause uterine irritability and induce premature labor when given to pregnant women who are near-term. ■ The effect of neostigmine on the mother and fetus with regard to labor, delivery, the need for forceps delivery or other intervention, or resuscitation of the newborn is not known. ■ Use caution during breast-feeding. ■ Recovery of neuromuscular activity occurs more rapidly with smaller doses of acetylcholinesterase inhibitors in pediatric patients than in adults. However, infants and small children may be at greater risk for complications from incomplete reversal of neuromuscular blockade due to decreased respiratory reserve. The risks associated with incomplete reversal outweigh any risk from giving higher doses of neostigmine. ■ Because blood pressure in pediatric patients, particularly infants and neonates, is sensitive to changes in heart rate, the effects of an anticholinergic agent (e.g., atropine) should be observed before administration of neostigmine to lessen the probability of bradycardia and hypotension.

Elderly:

Duration of action is prolonged in the elderly. However, the elderly also experience a slower spontaneous recovery from NMBAs. Dose adjustment is not generally needed, but an extended monitoring period to ensure complete reversal may be warranted.

DRUG/LAB INTERACTIONS

Pharmacokinetic interactions between neostigmine and other drugs have not been studied. ■ Metabolized by microsomal enzymes in the liver. Use with caution when using with other drugs that may alter the activity of metabolizing enzymes or transporters.

SIDE EFFECTS

Usually attributable to exaggerated pharmacologic effects at the muscarinic receptor. The most common side effects are bradycardia, nausea, and vomiting. Other side effects include dizziness, dry mouth, dyspnea, headache, hypotension, incision site complications, insomnia, oxygen desaturation, pharyngolaryngeal pain, postoperative shivering, procedural complications, procedural pain, prolonged neuromuscular blockade, pruritus, and tachycardia.

Overdose:

Bradycardia, nausea, vomiting, diarrhea, increased bronchial and salivary secretions, muscle weakness (including muscles of respiration), sweating, death (symptoms of cholinergic crisis).

Post-Marketing:

Hypersensitivity reactions, anaphylaxis, arthralgia, bowel cramps, bronchospasm, cardiac arrest, cardiac arrhythmias, convulsions, diaphoresis, diarrhea, drowsiness, dysarthria, fasciculation, flatulence, flushing, hypotension, increased peristalsis, increased secretions, loss of consciousness, miosis, muscle cramps, nonspecific ECG changes, rash, respiratory depression or arrest, spasms, syncope, urinary frequency, urticaria, visual changes, weakness.

ANTIDOTE

If side effects occur, discontinue drug and notify the physician. The use of an anticholinergic agent (atropine or glycopyrrolate) may prevent or mitigate most side effects, including cardiovascular complications (bradycardia, hypotension, or dysrhythmia). In the event of an overdose, ventilation should be supported by artificial means until adequacy of spontaneous respiration is assured, and cardiac function should be monitored. Treat anaphylaxis immediately with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

NICARDIPINE HYDROCHLORIDE

(nye-**KAR**-dih-peen hy-droh-**KLOR**-eyed)
Cardene IV
Calcium channel blocker
Antihypertensive
pH 3.5 to 4.7

USUAL DOSE

Must be individualized based on the severity of hypertension and the response of each patient. Blood pressure decrease is dependent on the rate of infusion and frequency of dose adjustments. Gradual reduction based on clinical situation is best. Avoid too-rapid or excessive drop in BP. See Precautions and Monitor. Transfer to oral medication as soon as clinical condition permits.

To substitute for oral nicardipine therapy:

0.5 mg/hr will achieve similar plasma concentration to an oral dose of 20 mg every 8 hours; 1.2 mg/hr to an oral dose of 30 mg every 8 hours; 2.2 mg/hr to an oral dose of 40 mg every 8 hours.

Gradual reduction of BP in a drug-free patient:

Initiate therapy at 5 mg/hr. May be increased by 2.5 mg/hr every 15 minutes until desired BP reduction is achieved. Do not exceed 15 mg/hr.

Rapid reduction of BP in a drug-free patient:

Initiate a 5-mg/hr dose as above, but increases of 2.5 mg/hr may be given every 5 minutes until desired BP reduction is achieved (AHA guidelines recommend 5 to 15 minutes). Do not exceed 15 mg/hr.

Maintenance:

Adjust as needed to maintain desired response.

Transfer to an oral antihypertensive agent:

The first dose of oral nicardipine should be given 1 hour before discontinuing infusion. Initiate any other oral antihypertensive agent on discontinuation of infusion.

DOSE ADJUSTMENTS

Lower doses and slower titration suggested in heart failure and impaired hepatic or renal function; see Precautions. ■ Lower-end initial doses may be indicated in the elderly. Consider potential for decreased organ function and concomitant disease or drug therapy. ■ Discontinue infusion if hypotension or tachycardia develop. When blood pressure and heart rate stabilize, restart infusion at a lower dose and titrate to desired response.

DILUTION

Available as a premixed solution containing a final concentration of 0.1 mg/mL or 0.2 mg/mL in D5W or NS. Also available in a vial that requires further dilution. Each vial (25 mg in 10 mL) must be diluted with 240 mL of **compatible** infusion solution to equal a concentration of 0.1 mg/mL; in this 0.1 mg/mL concentration, 2.5 mg/hr equals 25 mL/hr, 3 mg/hr equals 30 mL/hr, 5 mg/hr equals 50 mL/hr, and 15 mL/hr equals 150 mL/hr. **Compatible** in ½NS, NS, D5W, D5/½NS, D5NS. Also **compatible** in D5W with 40 mEq of potassium added.

Fluid-restricted or pediatric patients:

One source recommends mixing up to 50 mg in 100 mL (0.5 mg/mL). To avoid superficial phlebitis, administration via a central line is recommended for this concentration.

Filters:

No data available from manufacturer.

Storage:

Store vials in carton, protected from light at CRT. Has a light yellow color. Diluted solution is stable at room temperature for 24 hours. Store prediluted solutions at CRT; protect from light and excessive heat.

COMPATIBILITY

Manufacturer states, “Do not combine with any product in the same IV line or premixed container. Do not add supplementary medication to the bag.” Manufacturer lists as **incompatible** with sodium bicarbonate 5% and LR.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Must be administered as a slow, continuous infusion. Adjust as indicated in Usual Dose and Dose Adjustments.

ACTIONS

The first dihydropyridine calcium channel blocker for IV use. Inhibits influx of calcium ions into cardiac muscle and smooth muscle without altering serum calcium. Contractile processes are dependent on calcium movement through specific channels. Effects seen are more selective to vascular smooth muscle than cardiac muscle. Causes coronary and peripheral blood vessels to dilate and relax, reducing systemic vascular resistance. Increases cardiac output, coronary blood flow, and myocardial oxygen supply without increasing cardiac oxygen demand. Reduces BP without significantly affecting cardiac conduction and usually does not depress cardiac function. Produces dose-dependent decreases in BP. Begins to reduce BP in minutes; achieves 50% of ultimate decrease in 45 minutes. When discontinued, can lose 50% of effect within 30 minutes, but gradually decreasing effects persist for many hours. Effects more prominent in hypertensive than in normotensive volunteers. Highly protein bound. Extensively metabolized in the liver by the hepatic cytochrome P_{450} enzymes CYP2C8, 2D6, and 3A4. Half-life is 14 hours. Excreted in urine and feces. Crosses placental barrier. Minimally secreted in breast milk.

INDICATIONS AND USES

Short-term treatment of hypertension when oral therapy is not feasible or not desirable.

CONTRAINDICATIONS

Advanced aortic stenosis (reduced diastolic pressure may worsen rather than improve myocardial oxygen balance). ■ Known hypersensitivity to nicardipine.

PRECAUTIONS

Use caution in patients with coronary artery disease. May cause increase in frequency, duration, or severity of angina. ■ Has improved left ventricle function after betablockade. ■ Use caution and titrate slowly in patients with heart failure or significant left ventricular dysfunction, particularly when used in combination with a beta-blocker; possible negative inotropic effects may occur. ■ Use caution with impaired hepatic or renal function; lower doses, slower titration, and close monitoring indicated. ■ May produce symptomatic hypotension or tachycardia. Avoid systemic hypotension (systolic BP less than 90 mm Hg), and use with caution in patients with acute cerebral infarction or hemorrhage. ■ Experience with use in patients with hypertension from pheochromocytoma is limited.

Monitor:

To reduce the possibility of venous thrombosis, phlebitis, local irritation, swelling, extravasation, and/or vascular impairment, administer through a central vein or large peripheral vein rather than a small peripheral vein. Avoid intra-arterial administration. If administered via a peripheral vein, change the infusion site every 12 hours. ■ Avoid tachycardia or too-rapid or excessive reduction in either systolic or diastolic BP. Monitor BP and HR continually during infusion and frequently after infusion. Additional monitoring of BP and HR is indicated when used in combination with a beta-blocker in patients with HF or significant left ventricular dysfunction ■ Transfer to oral therapy as soon as clinical condition permits. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Request assistance to change position or ambulate.

Maternal/Child:

Category C: use during pregnancy only if benefit justifies potential risk to the fetus. Has been used for the treatment of severe hypertension in pregnancy and preterm labor. Changes in fetal heart rate and neonatal hypotension and acidosis have been reported. If treatment for hypertension during pregnancy is needed, other agents may be preferred. ■ Use caution during breast-feeding; infant exposure may occur. Some manufacturers do not recommend breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly:

Response similar to that seen in younger adults; however, greater sensitivity in the elderly cannot be ruled out. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

May cause possible negative inotropic effects with concurrent administration of a **beta-blocker**; see Precautions. ■ **Cimetidine** increases oral nicardipine plasma concentrations; monitor patients receiving IV nicardipine. ■ May increase plasma levels of **cyclosporine** and **tacrolimus** through inhibition of hepatic microsomal enzymes, including CYP3A4; monitor levels and adjust dose if indicated. ■ May potentiate the effects of **other antihypertensives.** Monitor BP closely and adjust doses as indicated. ■ Metabolism may be increased and serum concentrations decreased by **rifampin**. Adjust dose as needed.

SIDE EFFECTS

Average dose:

The most common side effects include headache, hypotension, nausea and vomiting, and tachycardia. Many other side effects, including ECG abnormality (e.g., angina pectoris, atrioventricular block, ST-segment depression, inverted T wave), confusion, conjunctivitis, deep vein thrombophlebitis, dyspepsia, ear disorder, fever, hypertonia, hypophosphatemia, neck pain, peripheral edema, respiratory difficulties, thrombocytopenia, tinnitus, and urinary frequency, occurred in fewer than 3% of patients. Hypersensitivity reactions (e.g., angioedema, rash, wheezing) have been reported.

Overdose:

Bradycardia (following initial tachycardia), confusion, drowsiness, flushing, hypotension (marked), palpitations, slurred speech.

Post-Marketing:

Decreased oxygen saturation (possible pulmonary shunting).

ANTIDOTE

Keep physician informed of all side effects. Headache, hypotension, and tachycardia have required a reduction in dose or discontinuation of nicardipine. When symptoms subside, nicardipine may be restarted at low doses (e.g., 3 to 5 mg/hr [30 to 50 mL/hr of a 0.1 mg/mL solution or 15 to 25 mL/hr of a 0.2 mg/mL solution]) and adjusted to maintain desired BP. In overdose, monitor BP and cardiac and respiratory functions; put patients in Trendelenburg position; use vasopressors (e.g., dopamine) for excessive hypotension. IV calcium gluconate may reverse effects of calcium entry blockade. Not removed by hemodialysis.

NITROGLYCERIN IV

(**NYE**-troe-**GLIS**-er-in)
Antianginal
Antihypertensive
Vasodilator
pH 3 to 6.5

USUAL DOSE

See Compatibility; these doses are recommended for use with non-PVC administration sets. Increased doses are required if using PVC administration sets. Dose must be individualized based on patient condition and response to therapy. Initiate infusion at 5 mcg/min. Subsequent titration must be guided by clinical results, with dose increments becoming more cautious as partial response is seen. Initial titration should be in 5-mcg/min increments at intervals of 3 to 5 minutes. If no response is seen at 20 mcg/min, increments of 10 mcg/min and even 20 mcg/min can be used. Once some hemodynamic response is observed, dosage increments should be smaller and less frequent.

Note: If the concentration of nitroglycerin is changed, the tubing must be disconnected from the patient and flushed with the new solution before therapy is continued. If this precaution is not taken, then it might take several hours before nitroglycerin is delivered at the desired rate depending on the tubing, pump, and flow rate used.

PEDIATRIC DOSE

0.25 to 0.5 mcg/kg/min initially. May increase by 0.5 to 1 mcg/kg/min increments every 3 to 5 minutes until desired response. Maximum dose suggested is 20 mcg/kg/min. See Maternal/Child. AHA guidelines recommend titrating by 1 mcg/kg/min every 15 to 20 minutes and state that the typical dose range is 1 to 5 mcg/kg/min. Maximum dose suggested is 10 mcg/kg/min.

DOSE ADJUSTMENTS

Lower-end initial doses may be appropriate in the elderly based on potential for decreased organ function, concomitant disease, or other drug therapy.

DILUTION

Available premixed in D5W with various concentrations of nitroglycerin. Do not use premixed solution if vacuum is not present. All other preparations must be diluted before administration as an infusion. Use only non-PVC plastic (EXCEL or PAB) or glass infusion bottles and specific (nonpolyvinyl chloride) infusion tubing. Do not use filters. Dilute in a given amount of D5W or NS for infusion. Concentration is dependent on initial preparation and patient fluid tolerances. Lower concentrations of nitroglycerin in D5W increase the potential for precision of dosing but increase the total fluid volume that must be administered. Total fluid load may be an important consideration in patients with compromised heart, hepatic, or renal function.

Filters:

Some in-line IV filters absorb nitroglycerin; these filters should be avoided.

Storage:

Store at CRT. Protect from light and freezing. Discard any unused portion of vial or premixed solution. Solution stable for up to 24 hours.

COMPATIBILITY

Manufacturer states, “Do not admix with any other drug.” See Dilution. Non-PVC plastic or glass infusion bottles and nonpolyvinyl chloride infusion tubing are required to deliver accurate dosing with minimal absorption. Calculated dose will not be correct if other infusion containers or tubing are used because of excess absorption.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Use of an infusion pump is required. Rate is dependent on patient response and effective dose. Specific adjustments required; see Usual Dose. Use extreme caution in patients responsive to initial 5 mcg/min dose. Decrease dose increments and increase time between dose adjustments as patient begins to respond.

Adult infusion rate may be calculated using the following equation:

Infusion rate (mL/hr) = [Dose (mcg/min) × 60 min/hr] ÷ Final concentration (mcg/mL)

Pediatric infusion rate may be calculated using the following equation:

Infusion rate (mL/hr) =

[Dose (mcg/kg/min) × Weight (kg) × 60 min/hr] ÷ Final concentration (mcg/mL)

(Use of the 100 mcg/mL [25 mg/250 mL] concentration is recommended.)

ACTIONS

The principal action of nitroglycerin is relaxation of vascular smooth muscle and consequent dilation of peripheral arteries and veins, especially the latter. Dilation of the veins promotes peripheral pooling of blood and decreases venous return to the heart, thereby reducing left ventricular end-diastolic pressure and pulmonary capillary wedge pressure (preload). Arteriolar relaxation reduces systemic vascular resistance, systolic arterial pressure, and mean arterial pressure (afterload). Dilation of the coronary arteries also occurs. The relative importance of preload reduction, afterload reduction, and coronary dilation remains undefined. Widely distributed throughout the body. Onset of action is immediate. Duration of effect is 3 to 5 minutes. Undergoes both hepatic and nonhepatic metabolism and is excreted in urine.

INDICATIONS AND USES

Treatment of perioperative hypertension. ■ Control of heart failure in the setting of acute myocardial infarction. ■ Treatment of angina pectoris if patient is unresponsive to sublingual nitroglycerin and beta-blockers. ■ Induction of intraoperative hypotension.

CONTRAINDICATIONS

Hypersensitivity to nitrates or any component of the product (dextrose is derived from corn). ■ Patients with pericardial tamponade, restrictive cardiomyopathy, constrictive pericarditis, or cardiac output that is dependent on venous return. ■ Patients with increased intracranial pressure or uncorrected hypovolemia. ■ Concurrent use with phosphodiesterase-5 (PDE-5) inhibitors (e.g., avanafil, sildenafil, tadalafil, or vardenafil) or with soluble guanylate cyclase stimulators (e.g., riociguat).

PRECAUTIONS

Use of polyvinyl chloride (PVC) tubing in infusion sets may lead to loss of active ingredient due to absorption of nitroglycerin by PVC tubing; therefore dosage is affected. Nitroglycerin absorption by PVC tubing is increased when the tubing is long, flow rates are low, and nitroglycerin concentration is high. PVC tubing was used in most published studies of IV nitroglycerin. The delivered fraction of the solution's original nitroglycerin content has been 20% to 60% in published studies. Relatively nonabsorptive IV administration sets are available. **If IV nitroglycerin is administered through nonabsorptive tubing, doses based on published reports will generally be too high.** ■ Severe hypotension and shock may occur with even small doses of nitroglycerin. Hypotension induced by nitroglycerin may be accompanied by paradoxical bradycardia and increased angina pectoris. ■ Nitrate therapy may aggravate angina caused by hypertrophic cardiomyopathy. ■ Tolerance development and occurrence of cross-tolerance to other nitro compounds have been reported. ■ Lower concentrations of nitroglycerin in D5W increase the potential for precision of dosing but increase the total fluid volume that must be administered. Total fluid load may be an important consideration in patients with compromised heart, hepatic, or renal function. ■ Methemoglobinemia has been reported (rare); see Antidote.

Monitor:

Continuous monitoring of BP and HR required. ■ Monitoring of pulmonary capillary wedge pressure may be indicated. ■ Closely monitor patients who may be volume depleted or who, for whatever reason, are already hypotensive. ■ Monitor blood glucose in patients with known subclinical or overt diabetes mellitus when using solutions containing dextrose. ■ Headache may improve with analgesics or slightly lower dose; usually improves with time. ■ See Drug/Lab Interactions.

Maternal/Child:

Safety for use in pregnancy, breast-feeding, and in pediatric patients not established. Consider risk versus benefit for each indication.

Elderly:

Differences in response compared with younger patients not identified. ■ Lower-end initial doses may be indicated; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Concurrent use with **phosphodiesterase-5 (PDE-5) inhibitors** (e.g., avanafil, sildenafil, tadalafil, or vardenafil) is contraindicated. Concomitant use can cause severe hypotension, syncope, or myocardial ischemia. ■ Concurrent use with **soluble guanylate cyclase stimulators** (e.g., riociguat) is contraindicated. Concomitant use can cause hypotension. ■ Potentiated by **alcohol, antihypertensives** (including **beta-adrenergic blockers** and **calcium channel blockers**), **other vasodilators, phenothiazines, and tricyclic antidepressants**. ■ **Dihydroergotamine** may diminish the vasodilatory effect of nitroglycerin. ■ May cause marked orthostatic hypotension with **calcium channel blockers**. ■ At higher doses, nitroglycerin may antagonize anticoagulant effects of **heparin;** monitor. ■ Concurrent use with **alteplase** (tPA) reduces the thrombolytic effects of alteplase. ■ **Serum triglyceride assays** that rely on glycerol oxidase may give falsely elevated results in patients receiving nitroglycerin in D5W.

SIDE EFFECTS

In general, side effects are dose-related, and almost all are the result of nitroglycerin's activity as a vasodilator. Headache is the most commonly reported adverse reaction. Other reactions include abdominal pain, angina, dizziness, dyspnea, hypersensitivity reactions (e.g., itching, tracheobronchitis, wheezing), hypotension, light-headedness, methemoglobinemia, nausea, postural hypotension, rebound hypotension, syncope, tachycardia, vomiting.

Overdose:

Bloody diarrhea, colic, coma, confusion, diaphoresis, dyspnea, fever, flushing, heart block, increased intracranial pressure, nausea and vomiting, palpitations, paradoxical bradycardia, paralysis, seizure, shock, syncope, tachycardia, visual disturbances, and death.

ANTIDOTE

Notify physician of all side effects. There is no specific antidote for overdose of nitroglycerin. The risk of overdose can be minimized by close monitoring during treatment. For significant adverse reactions, reduce rate or temporarily discontinue until condition stabilizes. Lower head of bed (Trendelenburg position). Administration of IV fluids may be useful but must be done with caution in patients with renal disease or heart failure. Invasive monitoring of hemodynamic status may be indicated to help guide therapy. Use O_2 and assisted ventilation if indicated. Epinephrine and related compounds (dopamine) are contraindicated. Monitor levels and treat methemoglobinemia if indicated with methylene blue 1 to 2 mg/kg IV and high-flow oxygen. Treat anaphylaxis and resuscitate as necessary.

NITROPRUSSIDE SODIUM BBW

(nye-troh-**PRUS**-eyed **SO**-dee-um)
Nipride RTU, Nitropress
Antihypertensive
Vasodilator
pH 3.5 to 6

USUAL DOSE

Continuous BP monitoring required.

Begin with 0.3 mcg/kg of body weight/min. Titrate in increments of 0.5 mcg/kg/min to a higher or lower dose to achieve the desired BP. Evaluate BP for at least 5 minutes before titrating to the next dose. (3 mcg/kg/min is the average effective dose; range is 0.1 to 10 mcg/kg/min.) AHA guidelines recommend beginning with 0.1 mcg/kg/min. Titrate upward every 3 to 5 minutes to desired effect (up to 5 mcg/kg/min). Small adjustments can lead to major fluctuations in BP. Dose may be titrated upward until the desired dose effect is achieved, the systemic BP cannot be further reduced without compromising the perfusion of vital organs, or the maximum recommended infusion rate of 10 mcg/kg/min has been reached, whichever occurs first. If 10 mcg/kg/min does not promote adequate BP reduction in 10 minutes, discontinue administration and use another antihypertensive agent. Cyanide toxicity can occur with as little as 2 mcg/kg/min and could begin to occur after 10 minutes at the maximum dose.

PEDIATRIC DOSE

Begin with 0.3 mcg/kg/min. Adjust slowly to individual response as in Usual Dose. AHA guidelines recommend 0.3 to 1 mcg/kg/min initially; titrate up to 8 mcg/kg/min as needed.

DOSE ADJUSTMENTS

Limit the mean infusion rate to less than 3 mcg/kg/min in patients with an eGFR less than 30 mL/min/1.73 M^2 and to 1 mcg/kg/min in anuric patients. ■ Reduced dose may be required in elderly patients.

DILUTION

Available as a ready-to-use (RTU) single-use vial containing 50 mg/100 mL of NS (0.5 mg/mL) and 10 mg/50 mL of NS (0.2 mg/mL). Also available in a concentrated liquid formulation (50 mg/2 mL). Must be further diluted in a minimum of 250 mL of D5W and administered as an infusion. Larger amounts of solution may be used. 50 mg in 250 mL equals 200 mcg/mL. 50 mg in 500 mL equals 100 mcg/mL. Immediately after mixing, wrap infusion bottle in opaque material (e.g., aluminum foil) to protect from light. Discard solution 24 hours after dilution. ■ Solution should be a clear, colorless to red/brown color; discard immediately if highly colored, blue, green, or bright red.

COMPATIBILITY

Manufacturer states, "Do not administer other drugs in the same solution with sodium nitroprusside."

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Use of an infusion pump (volumetric preferred) required to regulate dose accurately. Increase mcg/kg/min rate as outlined in Usual Dose to reduce BP gradually to preset or desired levels. Do not exceed maximum dose. Response should be noted almost immediately.

ACTIONS

A potent, rapid-acting antihypertensive agent. Produces peripheral vasodilation through direct action on smooth muscle of the blood vessels. Reduces left ventricular end diastolic pressure and pulmonary capillary wedge pressure (preload) and systemic vascular resistance, systolic arterial pressure, and mean arterial pressure (afterload). Effective almost immediately. May increase HR and/or cardiac output slightly. Effectiveness ends when IV infusion is stopped. BP will return to pretreatment levels in 1 to 10 minutes. Rapidly converted to thiocyanate and eventually excreted in the urine.

INDICATIONS AND USES

For the immediate reduction of blood pressure in adults and pediatric patients in hypertensive crises. ■ For induction and maintenance of controlled hypotension in adult and pediatric patients to reduce bleeding during surgery. ■ Treatment of acute heart failure to reduce left ventricular end-diastolic pressure, pulmonary capillary wedge pressure, peripheral vascular resistance, and mean arterial BP.

Unlabeled uses:

Hypertension during acute ischemic stroke.

CONTRAINDICATIONS

Diseases with compensatory hypertension (e.g., arteriovenous shunt or coarctation of the aorta). ■ Should not be used to produce hypotension during surgery in patients with known inadequate cerebral circulation or in moribund patients (ASA Class 5E) coming to emergency surgery. ■ Patients with congenital (Leber's) optic atrophy or tobacco amblyopia. ■ Acute heart failure associated with reduced peripheral vascular resistance. ■ Concomitant use with sildenafil, tadalafil, vardenafil, or riociguat.

PRECAUTIONS

Precipitous decreases in BP can occur quickly. Can lead to irreversible ischemic injuries or death. Hypotension should resolve within 1 to 10 minutes after discontinuation of the nitroprusside infusion. If hypotension persists, consider other causes. Use only when adequate personnel and appropriate equipment are available for continuous monitoring. ■ Nitroprusside metabolism produces dose-related cyanide, which can be lethal. ■ At infusions above 2 mcg/kg/min, cyanide ion is generated faster than the body can normally eliminate it. ■ A patient's ability to buffer cyanide will be exceeded in less than 1 hour at the maximum dose rate (10 mcg/kg/min); limit infusions at the maximum rate to as short a duration as possible. Patients with hepatic dysfunction are more susceptible to cyanide toxicity. ■ Most of the cyanide produced during metabolism of nitroprusside is eliminated in the form of thiocyanate. Thiocyanate is mildly neurotoxic at serum levels of 1 mmol/L (60 mg/L) and is life threatening when levels reach approximately 200 mg/L. ■ Nitroprusside infusions cause conversion of hemoglobin to methemoglobin in a dose-dependent manner. Clinically significant methemoglobinemia is infrequent. Suspect methemoglobinemia in patients who have received greater than 10 mg/kg of nitroprusside and who exhibit signs of impaired oxygen delivery despite adequate cardiac output and adequate arterial Po_2. ■ As with other vasodilators, nitroprusside can cause increases in intracranial pressure. ■ Use caution in hypothyroidism, increased intracranial pressure, liver or renal impairment, and elderly patients. ■ When nitroprusside (or any other vasodilator) is used for controlled hypotension during anesthesia, the patient's capacity to compensate for anemia and hypovolemia may be diminished. If possible, correct pre-existing anemia and hypovolemia before administration.

Monitor:

Determine patency of vein; avoid extravasation. ■ Continuous automatic BP monitoring is mandatory (intra-arterial pressure sensor preferred). ■ An early manifestation of cyanide toxicity is increasing dosage requirements to maintain blood pressure control. Metabolic acidosis may not be evident for more than an hour after toxic cyanide levels accumulate. ■ Monitor for S/S of thiocyanate toxicity (hyperreflexia, miosis, tinnitus). ■ Routine monitoring of thiocyanate plasma levels is recommended in patients with normal renal function when cumulative nitroprusside doses exceed 7 mg/kg/day; see Dose Adjustments. ■ Measure methemoglobin levels if indicated. Levels greater than 10% are considered clinically significant.

Patient Education:

Promptly report IV site burning or stinging.

Maternal/Child:

Safety for use in pregnancy not established. Information is limited. Prolonged use and large doses of nitroprusside during pregnancy may result in cyanide toxicity that may be fatal to the fetus. Consider risk versus benefit. Use should generally be avoided unless there is no appropriate alternative therapy. ■ Has been used in pediatric patients. Efficacy established, and safety concerns have not been identified. ■ Information on safety with breast-feeding not available. One source recommends that breast-feeding be discontinued.

Elderly:

See Dose Adjustments and Precautions. ■ May be more sensitive to the hypotensive effects. ■ Consider age-related renal impairment.

DRUG/LAB INTERACTIONS

Potentiated by most **other hypotensive agents**, including **ganglionic blocking agents**, **inhaled anesthetics**, and **negative inotropic agents**.

SIDE EFFECTS

Usually occur with too-rapid rate of infusion and are reversible. The most common adverse reactions are hypotension and cyanide toxicity. Less common adverse reactions include abdominal pain, apprehension, bradycardia, decreased platelet aggregation, diaphoresis, dizziness, ECG changes, flushing, headache, hypotension (profound), hypothyroidism, ileus, increased intracranial pressure, irritation at the infusion site, muscle twitching, nausea, palpitations, rash, restlessness, retching, retrosternal discomfort, tachycardia, venous streaking. Excessive hypotension, cyanide intoxication (air hunger, bright red venous blood, confusion, elevated cyanide levels, marked clinical deterioration, lactic acidosis, and death), or thiocyanate toxicity can occur with prolonged therapy or overdose. Methemoglobinemia (chocolate-brown blood, impaired oxygen delivery even though cardiac output and arterial PO_2 are adequate) can also occur.

ANTIDOTE

At first sign of side effects, decrease rate of administration. If BP begins to rise or side effects persist, notify the physician. For hypotension, slow or discontinue administration and put the patient in Trendelenburg position. Should improve in 1 to 10 minutes. If cyanide toxicity develops, discontinue nitroprusside and consider specific treatment for cyanide toxicity. For overdose with signs of cyanide toxicity or tachyphylaxis, discontinue nitroprusside sodium. Administer 3% sodium nitrite intravenously at a dose of 4 to 6 mg/kg over 2 to 4 minutes. Sodium nitrite provides a buffer for cyanide by converting hemoglobin into methemoglobin. Monitor BP carefully; may cause hypotension that will also require treatment. Next, inject sodium thiosulfate 150 to 200 mg/kg (usually about 12.5 Gm or 50 mL of the 25% solution) in 50 mL of D5W intravenously over 10 minutes. Sodium thiosulfate converts cyanide into thiocyanate, which is then excreted in urine. Observe patient. If signs of overdose reappear, may repeat the previously described process after 2 hours using one-half the original dosage. Treat methemoglobinemia with methylene blue 1 to 2 mg/kg. Hemodialysis is ineffective in the removal of cyanide but will eliminate thiocyanate in cases of severe toxicity.

NIVOLUMAB

(nye-**VOL**-ue-mab)
Opdivo
Antineoplastic
(Monoclonal antibody, anti-PD-1 monoclonal antibody)
pH 6

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor. Pretesting may be indicated based on diagnosis; see Indications and Uses.

Melanoma (single agent):

240 mg every 2 weeks or 480 mg every 4 weeks. Administered as an IV infusion over 30 minutes until disease progression or unacceptable toxicity.

Melanoma in combination with ipilimumab:

Nivolumab:

1 mg/kg as an IV infusion over 30 minutes, followed by ***ipilimumab*** 3 mg/kg as an IV infusion over 90 minutes on the same day every 3 weeks for a maximum of 4 doses or until unacceptable toxicity, whichever occurs earlier. The recommended subsequent dose of nivolumab as a single agent is 240 mg every 2 weeks or 480 mg every 4 weeks. Administered as an IV infusion over 30 minutes until disease progression or unacceptable toxicity. Review impilimumab monograph before initiating therapy.

Adjuvant treatment of melanoma:

240 mg every 2 weeks or 480 mg every 4 weeks. Administered as an IV infusion over 30 minutes until disease recurrence or unacceptable toxicity for up to 1 year.

Non–small-cell lung cancer (NSCLC), classical Hodgkin lymphoma (cHL), squamous cell carcinoma of the head and neck (SCCHN), urothelial carcinoma, and hepatocellular carcinoma (HCC):

240 mg every 2 weeks or 480 mg every 4 weeks. Administered as an IV infusion over 30 minutes until disease progression or unacceptable toxicity.

Small-cell lung cancer (SCLC):

240 mg administered as an IV infusion over 30 minutes every 2 weeks until disease progression or unacceptable toxicity.

Renal cell carcinoma (RCC) (single agent):

240 mg every 2 weeks or 480 mg every 4 weeks. Administered as an IV infusion over

30 minutes until disease progression or unacceptable toxicity.

Renal cell carcinoma (RCC) in combination with ipilimumab:

Nivolumab:

3 mg/kg as an IV infusion over 30 minutes, followed by ***ipilimumab*** 1 mg/kg as an IV infusion over 30 minutes on the same day every 3 weeks for 4 doses. The recommended subsequent dose of nivolumab as a single agent is 240 mg every 2 weeks or 480 mg every 4 weeks. Administered as an IV infusion over 30 minutes until disease progression or unacceptable toxicity. Review impilimumab monograph before initiating therapy.

Microsatellite instability–high (MSI-H) or mismatch repair deficient (dMMR) metastatic colorectal cancer (CRC) (single agent):

Adult and pediatric patients 12 years of age and older and weighing 40 kg or more: 240 mg administered as an IV infusion over 30 minutes every 2 weeks, or 480 mg administered as an IV infusion over 30 minutes every 4 weeks, until disease progression or unacceptable toxicity. ***Pediatric patients 12 years of age and older and weighing less than 40 kg:*** 3 mg/kg administered as an IV infusion over 30 minutes ever 2 weeks until disease progression or unacceptable toxicity.

Microsatellite instability–high (MSI-H) or mismatch repair deficient (dMMR) metastatic colorectal cancer (CRC) in combination with ipilimumab:

Nivolumab:

3 mg/kg as an IV infusion over 30 minutes, followed by ***ipilimumab*** 1 mg/kg as an IV infusion over 30 minutes on the same day every 3 weeks for 4 doses.

After completing 4 doses of combination therapy, administer nivolumab as single agent until disease progression or unacceptable toxicity.

Adult and pediatric patients 12 years of age and older weighing 40 kg or more:

240 mg as an IV infusion over 30 minutes every 2 weeks, or 480 mg as an IV infusion over 30 minutes every 4 weeks. ***Pediatric patients 12 years of age and older weighing less than 40 kg:*** 3 mg/kg administered as an IV infusion over 30 minutes every 2 weeks. Review impilimumab monograph before initiating therapy.

PEDIATRIC DOSE

Microsatellite instability–high (MSI-H) or mismatch repair deficient (dMMR) metastatic colorectal cancer (mCRC) in pediatric patients 12 years of age and older (single agent or in combination with ipilimumab):

See Usual Dose.

DOSE ADJUSTMENTS

Recommendations for nivolumab dose modifications are provided in the following chart. When nivolumab is administered in combination with ipilimumab, ipilimumab should be withheld if nivolumab is withheld. Review ipilimumab monograph for recommended dose modifications. ■ Initiate corticosteroid therapy for immune-mediated reactions and/or hormone replacement as outlined in Monitor.

Recommended Dose Modifications for Nivolumab

Adverse Reaction	Severity[a]	Dose Modification
Colitis	Grade 2 diarrhea or colitis	Withhold dose[b]
	Grade 3 diarrhea or colitis	Withhold dose[b] when administered as a single agent
		Permanently discontinue when administered with ipilimumab
	Grade 4 diarrhea or colitis	Permanently discontinue
Pneumonitis	Grade 2 pneumonitis	Withhold dose[b]
	Grade 3 or 4 pneumonitis	Permanently discontinue
Hepatitis/non-HCC[c]	AST or ALT more than 3 and up to 5 × ULN or total bilirubin more than 1.5 and up to 3 × ULN	Withhold dose[b]
	AST or ALT more than 5 × ULN or total bilirubin more than 3 × ULN	Permanently discontinue
Hepatitis/HCC[c]	AST/ALT within normal limits at baseline and increases to more than 3 and up to 5 × ULN AST/ALT more than 1 and up to 3 × ULN at baseline and increases to more than 5 and up to 10 × ULN AST/ALT more than 3 and up to 5 × ULN at baseline and increases to more than 8 and up to 10 × ULN	Withhold dose[d]
	AST or ALT increases to more than 10 × ULN or total bilirubin increases to more than 3 × ULN	Permanently discontinue
Hypophysitis	Grade 2 or 3 hypophysitis	Withhold dose[b]
	Grade 4 hypophysitis	Permanently discontinue
Adrenal insufficiency	Grade 2 adrenal insufficiency	Withhold dose[b]
	Grade 3 or 4 adrenal insufficiency	Permanently discontinue
Type 1 diabetes mellitus	Grade 3 hyperglycemia	Withhold dose[b]
	Grade 4 hyperglycemia	Permanently discontinue

Nephritis and renal dysfunction	SCr more than 1.5 and up to 6 × ULN	Withhold dose[b]
	SCr more than 6 × ULN	Permanently discontinue
Skin	Grade 3 rash or suspected Stevens-Johnson syndrome (SJS) or toxic epidermal necrolysis (TEN)	Withhold dose[b]
	Grade 4 rash or confirmed SJS or TEN	Permanently discontinue
Encephalitis	New-onset moderate or severe neurologic S/S	Withhold dose[b]
	Immune-mediated encephalitis	Permanently discontinue
Other	Other Grade 3 adverse reaction First occurrence Recurrence of the same Grade 3 adverse reaction	Withhold dose[b] Permanently discontinue
	Life-threatening or Grade 4 adverse reaction	Permanently discontinue
	Grade 3 myocarditis	Permanently discontinue
	Requirement of 10 mg/day or greater prednisone or equivalent for more than 12 weeks	Permanently discontinue
	Persistent Grade 2 or 3 adverse reactions lasting 12 weeks or longer	Permanently discontinue

[a] Toxicity graded per National Cancer Institute Common Terminology Criteria for Adverse Events, v4.0 (NCI CTCAE v4).

[b] Resume treatment when adverse reactions return to Grade 0 or 1.

[c] *HCC*, Hepatocellular carcinoma.

[d] Resume treatment when AST/ALT returns to baseline.

■ No recommended dose modifications for hypothyroidism or hyperthyroidism. ■ The pharmacokinetics of nivolumab do not appear to be affected by age, weight, sex, race, baseline LDH, PD-L1 expression, solid tumor type, tumor size, renal impairment (eGFR greater than or equal to 15 mL/min/1.73 M^2), mild hepatic impairment (total bilirubin [TB] less than or equal to the ULN and AST greater than ULN or TB greater than 1 to 1.5 times ULN and any AST), or moderate hepatic impairment (TB greater than 1.5 to 3 times ULN and any AST). Nivolumab has not been studied in patients with severe hepatic impairment (total bilirubin greater than 3 times the ULN and any AST). ■ See Monitor and Antidote.

DILUTION

Available as a solution in single-use vials containing 40 mg/4 mL, 100 mg/10 mL, or 240 mg/24 mL (10 mg/mL). Discard the vial if the solution is cloudy, discolored, or contains extraneous particulate matter other than a few translucent-to-white, proteinaceous particles. Calculate the number of vials required for the recommended dose, and withdraw the required volume of nivolumab and transfer into an IV bag or container of NS or D5W to prepare an infusion with a final concentration ranging from 1 to 10 mg/mL. For adult and pediatric patients with body weight equal to or greater than 40 kg, do not exceed a total volume of infusion of 160 mL. For adult and pediatric patients with body weight less than 40 kg, the total volume of infusion must not exceed 4 mL/kg of body weight. Mix diluted solution by gentle inversion. ***Do not shake***.

Filters:

Must be administered using IV tubing that contains a sterile, nonpyrogenic, low–protein-binding, in-line filter (pore size of 0.2 to 1.2 micrometers).

Storage:

Before use, refrigerate at 2° to 8° C (36° to 46° F) in original package to protect from light. Do not freeze or shake. Nivolumab does not contain a preservative. After preparation, store the prepared infusion at room temperature for no more than 8 hours or refrigerate for no more than 24 hours from the time of preparation. Administration time is included in storage time. Do not freeze. Discard partially used vials.

COMPATIBILITY

Manufacturer states, “Do not coadminister other drugs through the same intravenous line.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 minutes. Interrupt or slow rate of administration in patients with mild or moderate infusion reactions. If a common IV line is used to administer other drugs in addition to nivolumab, flush the IV line before and after each nivolumab infusion with NS or D5W. Administer through an IV tubing that contains a sterile, nonpyrogenic, low–protein-binding, in-line filter (pore size of 0.2 to 1.2 micrometers). When administered in combination with ipilimumab, infuse nivolumab first, followed by ipilimumab on the same day. Use separate infusion bags and filters for each infusion.

ACTIONS

An antineoplastic agent. Nivolumab is a programmed death receptor-1 (PD-1) blocking antibody; a human immunoglobulin G4 (IgG4) monoclonal antibody that binds to the PD-1 receptor and blocks its interaction with PD-L1 and PD-L2, thereby releasing PD-1 pathway–mediated inhibition of the immune response, including the antitumor immune response. In syngeneic mouse tumor models, blocking PD-1 activity resulted in decreased tumor growth. Combining nivolumab with ipilimumab results in enhanced T-cell function that is greater than the effects of either antibody alone and results in improved antitumor responses in metastatic melanoma and advanced RCC. Mean elimination half-life is 25 days. Steady-state concentrations were reached by 12 weeks when administered at 3 mg/kg every 2 weeks.

INDICATIONS AND USES

As a single agent or in combination with ipilimumab (Yervoy) for the treatment of patients with unresectable or metastatic melanoma. ■ Adjuvant treatment of patients with melanoma with involvement of lymph nodes or metastatic disease who have undergone complete resection. ■ Treatment of patients with metastatic non–small-cell lung cancer (NSCLC) with progression on or after platinum-based chemotherapy. Before receiving nivolumab, patients with EGFR or ALK genomic tumor aberrations should have experienced disease progression while undergoing FDA-approved therapy for these aberrations. ■ Treatment of patients with metastatic small-cell lung cancer (SCLC) with progression after platinum-based chemotherapy and at least one other line of therapy; see Limitation of Use. ■ As a single agent for the treatment of patients with advanced renal cell carcinoma (RCC) who have received prior antiangiogenic therapy. ■ In combination with ipilimumab (Yervoy) for the treatment of patients with intermediate or poor risk, previously untreated advanced RCC. ■ Treatment of patients with classical Hodgkin lymphoma (cHL) that has relapsed or progressed after autologous hematopoietic stem cell transplantation (HSCT) and brentuximab vedotin (Adcetris) or 3 or more lines of systemic therapy that includes autologous HSCT; see Limitation of Use. ■ Treatment of patients with recurrent or metastatic squamous cell carcinoma of the head and neck (SCCHN) with disease progression on or after platinum-based therapy. ■ Treatment of patients with locally advanced or metastatic urothelial carcinoma who have disease progression during or after platinum-containing chemotherapy or who have disease progression within 12 months of neoadjuvant or adjuvant treatment with platinum-containing chemotherapy; see Limitation of Use. ■ As a single agent or in combination with ipilimumab (Yervoy) for the treatment of adult and pediatric patients 12 years of age and older with microsatellite instability–high (MSI-H) or mismatch repair deficient (dMMR) metastatic colorectal cancer (CRC) that has progressed after treatment with fluoropyrimidine, oxaliplatin, and irinotecan; see Limitation of Use. ■ Treatment of patients with hepatocellular carcinoma (HCC) who have been previously treated with sorafenib; see Limitation of Use.

Limitation of use:

Specified indications have received accelerated approval. This accelerated approval is based on progression-free survival, tumor response rate, duration of response, or overall response rate. Continued approval may be contingent on verification and description of clinical benefit in the confirmatory trials.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Severe immune-mediated pneumonitis, including fatal cases, has occurred with nivolumab treatment. ■ Severe immune-mediated colitis (including cytomegalovirus [CMV] infection/reactivation) has been reported. ■ Immune-mediated hepatitis and liver test abnormalities (elevated ALT, AST, alkaline phosphatase, total bilirubin) have occurred with nivolumab treatment. ■ Immune-mediated nephritis has occurred with nivolumab treatment. ■ Pneumonitis, colitis, hepatitis, and nephritis (renal dysfunction or Grade 2 or higher increased SCr) were defined as immune-mediated when corticosteroids were required for treatment and there was no clear alternate etiology. ■ Immune-mediated endocrinopathies, including hypophysitis, adrenal insufficiency, type 1 diabetes mellitus (with possible diabetic ketoacidosis), hypothyroidism, and hyperthyroidism, have been reported. ■ Immune-mediated skin adverse reactions can occur. Rare cases of Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) have been reported. ■ Immune-mediated encephalitis with no clear alternate etiology can occur with nivolumab treatment. ■ Numerous other immune-mediated adverse reactions, some with fatal outcome, were reported in fewer than 1% of patients. ■ Severe infusion reactions have been reported. ■ Complications (e.g., acute, chronic or hyperacute graft-versus-host disease [GVHD], steroid-requiring febrile syndrome, hepatic veno-occlusive disease [VOD]), including fatal events, occurred in patients who received allogeneic HSCT despite intervening therapy with a PD-1 receptor–blocking antibody. ■ Increased mortality occurred in patients with multiple myeloma when nivolumab is added to a thalidomide analog and dexamethasone. ■ See Dose Adjustments, Monitor, and Antidote for required Dose Adjustments, indicated criteria and medications for treatment, and criteria for withholding or discontinuation of nivolumab. ■ Nivolumab has not been studied in patients with severe hepatic impairment. ■ A protein substance; has a potential for immunogenicity.

Monitor:

Obtain serum electrolytes and glucose, baseline liver function tests (e.g., ALT, AST, alkaline phosphatase, total bilirubin), serum creatinine, and thyroid function tests before initiating treatment, and monitor periodically during treatment and as indicated based on clinical evaluation. ■ Monitor for infusion reactions; see Dose Adjustments and Rate of Administration. Infusion reactions have occurred up to 48 hours after the infusion and may lead to dose delay, withholding of nivolumab, or permanent discontinuation. ■ Monitor patients for S/S of pneumonitis (e.g., abnormal chest x-ray, chest pain, new or worsening cough, or shortness of breath). Administer corticosteroids at a dose of 1 to 2 mg/kg/day prednisone equivalents for moderate (Grade 2) or more severe (Grade 3 or 4) pneumonitis, followed by corticosteroid taper. Withhold nivolumab until resolution for moderate (Grade 2) pneumonitis; see Dose Adjustments. ■ Monitor patients for colitis. Administer corticosteroids at a dose of 0.5 to 1 mg/kg/day prednisone equivalents followed by corticosteroid taper for moderate (Grade 2) colitis of more than 5 days' duration; if worsening or no improvement occurs despite initiation of corticosteroids, increase dose to 1 to 2 mg/kg/day prednisone equivalents. Administer corticosteroids at a dose of 1 to 2 mg/kg/day prednisone equivalents followed by corticosteroid taper for severe (Grade 3) or life-threatening (Grade 4) colitis. Withhold nivolumab for moderate (Grade 2) or severe (Grade 3) colitis when used as a single agent or for moderate (Grade 2) colitis when used in combination with ipilimumab; see Dose Adjustments. ■ In cases of corticosteroid-refractory colitis, consider repeating infectious workup to exclude alternative etiologies. Addition of an alternative immunosuppressive agent to the corticosteroid therapy, or replacement of the corticosteroid therapy, should be considered if other causes are excluded. ■ Monitor for S/S of hepatitis (e.g., easy bruising or bleeding, jaundice, lethargy, pain on the right side of the abdomen, severe nausea or vomiting, abnormal LFTs). Administer corticosteroids at a dose of 0.5 to 1 mg/kg/day prednisone equivalents for moderate

(Grade 2) transaminase elevations. Administer corticosteroids at a dose of 1 to 2 mg/kg/day prednisone equivalents followed by corticosteroid taper for severe (Grade 3) or life-threatening (Grade 4) transaminase elevations, with or without concomitant elevations in total bilirubin. For patients without HCC, withhold nivolumab for moderate (Grade 2) immune-mediated hepatitis and permanently discontinue for severe (Grade 3) or life-threatening (Grade 4) immune-mediated hepatitis. For patients with HCC, permanently discontinue, withhold, or continue nivolumab based on severity of immune-mediated hepatitis and baseline AST and ALT levels as outlined in Dose Adjustments. In addition, administer corticosteroids at a dose of 1 to 2 mg/kg/day prednisone equivalents followed by corticosteroid taper when nivolumab is withheld or discontinued due to immune-mediated hepatitis; see Dose Adjustments. ■ Monitor renal function periodically. For moderate (Grade 2) or severe (Grade 3) SCr elevation, withhold nivolumab and administer corticosteroids at a dose of 0.5 to 1 mg/kg/day prednisone equivalents followed by corticosteroid taper; if worsening or no improvement occurs, increase dose of corticosteroids to 1 to 2 mg/kg/day prednisone equivalents. Administer corticosteroids at a dose of 1 to 2 mg/kg/day prednisone equivalents followed by corticosteroid taper for life-threatening (Grade 4) SCr elevation, and permanently discontinue nivolumab; see Dose Adjustments. ■ Monitor for S/S of hypophysitis (e.g., fatigue, headache, low levels of the hormones produced by the pituitary [adrenocorticotropic hormone (ACTH), thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), luteinizing hormone (LH), growth hormone (GH), prolactin]). Administer hormone replacement as clinically indicated and corticosteroids at a dose of 1 mg/kg/day prednisone equivalents for moderate (Grade 2) or higher hypophysitis. Withhold nivolumab for moderate (Grade 2) or severe (Grade 3) hypophysitis; see Dose Adjustments. ■ Monitor for S/S of adrenal insufficiency (e.g., fatigue, nausea, vomiting, hypotension, hyponatremia, hyperkalemia, low cortisol concentrations). Administer corticosteroids at a dose of 1 to 2 mg/kg/day prednisone equivalents followed by corticosteroid taper for severe (Grade 3) or life-threatening (Grade 4) adrenal insufficiency. Hormone replacement therapy was required in more than half of patients who developed adrenal insufficiency. Withhold nivolumab for moderate (Grade 2) adrenal insufficiency; see Dose Adjustments. ■ Monitor for changes in thyroid function. Administer hormone replacement therapy for hypothyroidism. Initiate medical management for control of hyperthyroidism (e.g., methimazole, propylthiouracil). Administration of corticosteroids was required in some patients; see Dose Adjustments. ■ Monitor for hyperglycemia. Administer insulin when clinically indicated. Withhold nivolumab for severe (Grade 3) hyperglycemia until metabolic control is achieved; see Dose Adjustments. ■ Monitor for development of a rash. Administer corticosteroids at a dose of 1 to 2 mg/kg/day prednisone equivalents followed by corticosteroid taper for severe (Grade 3) or life-threatening (Grade 4) rash. Withhold nivolumab for suspected SJS or TEN or severe (Grade 3) rash; see Dose Adjustments. ■ Monitor for changes in neurologic status. Withhold nivolumab in patients with new-onset moderate to severe neurologic signs or symptoms. Evaluate patient to rule out infectious or other causes of moderate to severe neurologic deterioration. Evaluation may include, but is not limited to, consultation with a neurologist, brain MRI, and lumbar puncture. If other etiologies are ruled out, administer corticosteroids at a dose of 1 to 2 mg/kg/day prednisone equivalents, followed by a prednisone taper; see Dose Adjustments. ■ Monitor patient for any other clinically significant immune-mediated adverse reactions. Immune-mediated adverse reactions may occur after nivolumab is discontinued. Examples of other immune-mediated adverse reactions that have occurred include aplastic anemia, autoimmune neuropathy, demyelination, duodenitis, facial and abducens nerve paresis, gastritis, Guillain-Barré syndrome, histiocytic necrotizing lymphadenitis, hypopituitarism, iritis, motor dysfunction, myasthenic syndrome, myocarditis, myositis, pancreatitis, pericarditis, polymyalgia rheumatica, rhabdomyolysis, sarcoidosis, systemic inflammatory response syndrome, uveitis, and vasculitis. If uveitis occurs in combination with other immune-mediated adverse reactions, consider a Vogt-Koyanagi-Harada–like syndrome, which may require treatment with systemic steroids to reduce the risk of permanent vison loss. For any suspected immune-mediated adverse reactions, exclude other causes. Based on the severity of the adverse reaction, withhold or discontinue nivolumab, administer high-dose corticosteroids and, if appropriate, initiate hormone-replacement therapy. Upon improvement to Grade 1 or less, initiate corticosteroid taper and continue to taper over at least 1 month. Consider restarting nivolumab after completion of corticosteroid taper based on the severity of the event. ■ Monitor for early evidence of HSCT-related complications such as hyperacute GVHD, severe acute GVHD, steroid-requiring febrile syndrome, hepatic VOD, and other immune-mediated adverse reactions, and intervene promptly.

Patient Education:

Review manufacturer’s medication guide. ■ Effective contraception required during treatment with nivolumab and for at least 5 months following the last dose of nivolumab. ■ Promptly report a known or suspected pregnancy. ■ Some side effects may require corticosteroid treatment and interruption or discontinuation of nivolumab. ■ Promptly report any S/S of an infusion-related reaction. ■ Promptly report S/S of pneumonitis (e.g., chest pain, new or worsening cough, or shortness of breath). ■ Promptly report S/S of colitis (e.g., diarrhea or severe abdominal pain). ■ Promptly report S/S of hepatitis (e.g., easy bruising or bleeding, jaundice, lethargy, pain on the right side of the abdomen, severe nausea or vomiting). ■ Promptly report S/S of kidney dysfunction (e.g., blood in urine, decreased urine output, loss of appetite, swelling in ankles). ■ Promptly report S/S of hypophysitis, adrenal insufficiency, hypothyroidism, hyperthyroidism, or diabetes mellitus; see Monitor. ■ Promptly report S/S of encephalitis; see Monitor. ■ Promptly report development of a rash. ■ Keeping scheduled appointments for blood work or other laboratory tests is imperative.

Maternal/Child:

Avoid pregnancy. Based on mechanism of action and data from animal studies, nivolumab can cause fetal harm when administered to a pregnant woman. Human IgG4 is known to cross the placental barrier, and nivolumab is an IgG4. Effects of nivolumab are likely to be greater during the second and third trimesters of pregnancy. ■ Do not breast-feed during treatment and for 5 months after the last dose. ■ Safety and effectiveness as a single agent and in combination with ipilimumab have been established in pediatric patients 12 years of age and older with microsatellite instability–high (MSI-H) or mismatch repair deficient (dMMR) metastatic colorectal cancer (mCRC) that has progressed after treatment with fluoropyrimidine, oxaliplatin, and irinotecan. Safety and effectiveness have not been established in pediatric patients under 12 years of age with MSI-H or dMMR mCRC or in pediatric patients of any age for other approved indications.

Elderly:

No overall differences in safety or efficacy were reported between elderly patients and younger patients.

DRUG/LAB INTERACTIONS

No formal pharmacokinetic drug-drug interaction studies conducted with nivolumab.

SIDE EFFECTS

Several immune-mediated reactions have been reported, including colitis, encephalitis, endocrinopathies, hepatitis, nephritis and renal dysfunction, pneumonitis, and adverse skin reactions/rash; see Precautions, Monitor, and Antidote.

Single agent:

The most common adverse reactions were abdominal pain, arthralgia, asthenia, back pain, constipation, cough, decreased appetite, diarrhea, dyspnea, fatigue, fever, headache, musculoskeletal pain, nausea, pruritus, rash, upper respiratory infection, and vomiting. Other reported side effects included arrhythmia (ventricular), dizziness, dry skin, edema, erythema multiforme, exfoliative dermatitis, general physical health deterioration, infusion-related reactions, insomnia, iridocyclitis, myositis (including polymyositis), peripheral and sensory neuropathy, peripheral edema, pneumonia, psoriasis, sepsis, small intestine obstruction, urinary tract infection, vitiligo, and weight loss. Laboratory abnormalities included anemia; hypercalcemia, hyperglycemia; hyperkalemia; hypocalcemia; hypomagnesemia; hyponatremia; increased alkaline phosphate, ALT, amylase, AST, bilirubin, cholesterol, creatinine, lipase, and triglycerides; leukopenia; lymphopenia; neutropenia; thrombocytopenia. Other side effects may occur based on diagnosis.

Combination therapy:

The most common adverse reactions were abdominal pain, arthralgia, cough, decreased appetite, diarrhea, dyspnea, fatigue, fever, musculoskeletal pain, nausea, pruritis, rash, upper respiratory tract infection, and vomiting. Other reported side effects included constipation, dizziness, dry skin, edema, headache, insomnia, myositis (including polymyositis), and weight loss. Laboratory abnormalities included anemia; hyperglycemia; hyperkalemia; hypocalcemia; hypomagnesemia; hyponatremia; increased alkaline phosphate, ALT, amylase, AST, creatinine, and lipase; and lymphopenia.

Post-Marketing:

Treatment refractory, severe acute and chronic GVHD, Vogt-Koyanagi-Harada (VKH) syndrome.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Treat side effects aggressively; see Monitor. Follow guidelines for withholding or discontinuing therapy as outlined in Dose Adjustments. Interrupt or slow the rate of administration in patients with mild or moderate infusion reactions. Discontinue in patients with a severe or life-threatening infusion reaction and treat as indicated. Initiate corticosteroid therapy as outlined in Monitor for immune-mediated reactions (e.g., pneumonitis, colitis, hepatitis/HCC, renal dysfunction, hypophysitis, adrenal insufficiency, hyperthyroidism or hypothyroidism, rash, neurologic status, and other clinically significant immune-mediated adverse reactions). Hormone replacement may also be indicated; see Monitor. In clinical studies, infliximab was added to high-dose corticosteroid therapy for treatment of colitis, encephalitis, and pneumonitis in select patients. Mycophenolic acid was added for select patients with hepatitis. Resuscitate if indicated.

NIVOLUMAB AND RELATLIMAB

(nye-**VOL**-ue-mab and rel-**AT**-li-mab)
Opdualag
Antineoplastic agent; anti-LAG-3 monoclonal antibody: anti-PD-1 monoclonal antibody; immune checkpoint inhibitor

Check label to ensure that the appropriate product is being administered; “nivolumab and relatlimab” and “nivolumab” are different products and not interchangeable.

USUAL DOSE

Nivolumab 480 mg and relatlimab 160 mg IV once every 4 weeks until disease progression or unacceptable toxicity

PEDIATRIC DOSE

Children greater than or equal to 12 years and adolescents weighing at least 40 kg: nivolumab 480 mg and relatlimab 160 mg IV once every 4 weeks until disease progression or unacceptable toxicity

DOSE ADJUSTMENTS

Renal:

No dosage adjustments are provided by the manufacturer, unless the patient develops nephritis with kidney dysfunction during treatment; refer to package insert for details.

Hepatic:

No dosage adjustments are provided by the manufacturer, unless the patient develops hepatotoxicity during treatment; refer to package insert for details.

Adverse reactions during treatment:

Refer to package insert for details.

DILUTION

Nivolumab and relatlimab may be administered diluted or undiluted. Withdraw the required volume of nivolumab and relatlimab and transfer to an empty IV container made of DEHP-plasticized PVC, ethyl vinyl acetate, or polyolefin. If diluting prior to administration, dilute with NS or D5W and gently invert to mix (do not shake). The concentration for administration should range from 3 to 12 mg/mL (nivolumab component) and from 1 to 4 mg/mL (relatlimab component); the maximum infusion volume should be 160 mL (if weight ≥ 40 kg) or 4 mL/kg (if weight < 40 kg). Solution should be clear to opalescent, colorless to slightly yellow; discard vial if cloudy or discolored or contains extraneous particulate matter (other than a few translucent-to-white particles).

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions.

RATE OF ADMINISTRATION

Infuse over 30 minutes via an IV containing a sterile, nonpyrogenic, low-protein-binding polyethersulfone nylon or polyvinylidene fluoride 0.2- to 1.2-micrometer in-line filter. Flush IV line at the end of the infusion. Do not administer other medications through the same IV line. Monitor for S/S of infusion-related reactions.

ACTIONS

Relatlimab is a human IgG4 monoclonal antibody that binds to the LAG-3 receptor and blocks interaction between LAG-3 and its ligands to reduce LAG-3 pathway-mediated immune response inhibition; antagonism of this pathway promotes T-cell proliferation and cytokine secretion. Nivolumab is a human IgG monoclonal antibody that binds to the PD-1 receptor and blocks interaction with its ligands PD-L1 and PD-L2 and reduces PD-1 pathway-mediated inhibition of the immune response, including the anti-tumor immune response. Binding of the PD-1 ligands PD-L1 and PD-L2 to the PD-1 receptor found on T-cells inhibits T-cell proliferation and cytokine production. Upregulation of PD-1 ligands occurs in some tumors: therefore, signaling through this pathway can contribute to inhibition of active T-cell immune surveillance of tumors. Combining nivolumab (anti-PD1) and relatlimab (anti-LAG-3) results in increased T-cell activation compared to the activity of either antibody alone.

INDICATIONS AND USES

Treatment of unresectable or metastatic melanoma in adult and pediatric patients ≥ 12 years of age.

CONTRAINDICATIONS

No contraindications listed in the manufacturer’s labeling.

PRECAUTIONS

Hypersensitivity:

Immediately discontinue infusion with any signs of allergic reaction and institute appropriate care.

Hypernatremia and hypokalemia:

Monitor serum sodium and potassium at baseline and as clinically indicated. Withhold infusion if serum sodium is greater than 145 mmol/L.

Nausea and vomiting:

Administer antiemetics prior to each infusion.

Monitor:

Monitor hepatic ALT, AST, and total bilirubin at baseline and periodically during treatment and renal function and thyroid function at baseline and periodically during treatment. Monitor for hyperglycemia. Verify pregnancy status prior to treatment. Monitor closely for S/S of immune-mediated adverse reactions, including adrenal insufficiency, hypophysitis, thyroid disorders, diabetes, diarrhea/colitis (consider initiating or repeating infectious workup in patients with corticosteroid-refractory immune-mediated colitis to exclude alternative causes), myocarditis, pneumonitis, rash/dermatologic toxicity, neurotoxicity, and ocular disorders. If suspected immune-mediated reactions occur, initiate appropriate workup to exclude alternative causes (including infection). If patient has received or is receiving a hematopoietic stem cell transplant, monitor closely for early S/S of transplant-related complications. Monitor for S/S of infusion-related reactions. Screen for hepatitis B.

Patient Education:

Notify provider immediately if the patient shows signs of: ■ *High blood sugar*, such as confusion, feeling sleepy, greater thirst, hungrier, passing urine more often, flushing, fast breathing, or breath that smells like fruit. ■ *Infection*, such as fever, chills, or sore throat. ■ *Liver problems*, such as dark urine, feeling tired, not hungry, upset stomach, light-colored stools, throwing up, or yellow skin or eyes. ■ *Kidney problems*, such as not being able to pass urine, change in how much urine is passed, bloody brown or foamy urine, shortness of breath or cough, or puffy or swollen face, feet, or hands. ■ *Eye problems*, such as changes in eyesight, eye pain or irritation. ■ *Thyroid, pituitary, or adrenal gland problems*, such as change in mood or behavior, change in weight or taste, constipation, deeper voice, dizziness, fainting, feeling cold, feeling tired, hair loss, sever headache, change in desire for sex, eye problems, fast heartbeat, more sweating, fast or deep breathing, sweet-smelling breath, change in smell of urine or sweat, or passing urine more often. ■ *Severe skin reactions*, such as red, swollen, blistered, or peeling skin (with or without fever); red or irritated eyes; or sores in mouth throat, nose, or eyes. ■ *Pancreas problems*, such as stomach pain, very bad back pain, or throwing up. ■ *Lung or breathing problems*, such as shortness of breath or other trouble breathing, cough, or fever. ■ *Heart problems*, such as chest pain; fast, slow, abnormal heartbeat; or shortness of breath. ■ *Nervous system problems*, such as change in balance, change in mood or behavior, feeling confused or sleepy, fever, memory problems, severe muscle weakness, numbness or tingling in arms or legs, seizures, stiff neck, or being bothered by bright lights. ■ *Bowel problems*, such as black, tarry, or bloody stools; fever; mucus in stools; throwing up blood or vomit that looks like coffee grounds; severe stomach pain; or constipation or diarrhea. ■ *Low sodium levels*, as indicated by headache; trouble focusing; memory problems; feeling confused; weakness; seizures or change in balance; any unexplained bruising or bleeding; swelling in arms or legs; muscle cramps. ■ *Signs of an allergic reaction*, such as hives; itching; red, swollen, blistered or peeling skin with or without fever; wheezing; tightness of chest; trouble with breathing, swallowing, or talking; unusual hoarseness; or swelling of mouth, face, lips, tongue, or throat

Maternal/child:

Verify pregnancy status prior to treatment initiation. Patients who could become pregnant should use effective contraceptive measures during treatment and for at least 5 months after last dose. Based on animal data, in utero exposure may cause fetal harm. It is not known if the drug is present in breast milk. Due to the potential for serious adverse reaction, breastfeeding is not recommended during treatment and for at least 5 months after the last dose.

Elderly:

No specific recommendations; refer to adult dosing.

DRUG/LAB INTERACTIONS

Acetaminophen, systemic steroids, proton pump inhibitors, and efgartigimod alfa may diminish the effects of nivolumab and relatlimab. Desmopressin may have enhanced hyponatremic effects. Ketoconazole may have enhanced hepatotoxicity.

SIDE EFFECTS

High blood sugar, indicated by confusion, feeling sleepy, greater thirst, hungrier, passing urine more often, flushing, or fast breathing or breath that smells like fruit. ■ *Infection*, indicated by fever, chills, or sore throat. ■ *Liver problems*, indicated by dark urine, feeling tired, not hungry, upset stomach, light-colored stools, throwing up, or yellow skin or eyes. ■ *Kidney problems*, indicated by not being able to pass urine; change in how much urine is passed, bloody brown or foamy urine, shortness of breath or cough, or puffy or swollen face, feet, or hands. ■ *Eye problems*, indicated by changes in eyesight, eye pain, or eye irritation. ■ *Thyroid, pituitary, or adrenal gland problems*, indicated by change in mood or behavior, change in weight or taste, constipation, deeper voice, dizziness, fainting, feeling cold, feeling tired, hair loss, severe headache, change in desire for sex, eye problems, fast heartbeat, more sweating, fast or deep breathing, sweet-smelling breath, change in smell of urine or sweat, or passing urine more often. ■ *Severe skin reactions*, indicated by red, swollen, blistered, or peeling skin (with or without fever); red or irritated eyes, or sores in mouth throat, nose, or eyes. ■ *Pancreas problems*, indicated by stomach pain, very bad back pain, or throwing up. ■ *Lung or breathing problems*, indicated by shortness of breath or other trouble breathing, cough, or fever. ■ *Heart problems*, indicated by chest pain; fast, slow, abnormal heartbeat; or shortness of breath. ■ *Nervous system problems*, indicated by change in balance, change in mood or behavior, feeling confused or sleepy, fever, memory problems, severe muscle weakness, numbness or tingling in arms or legs, seizures, stiff neck, or being bothered by bright lights. ■ *Bowel problems*, indicated by black, tarry, or bloody stools; fever; mucus in stools; throwing up blood or vomit looking like coffee grounds; severe stomach pain; or constipation or diarrhea. ■ *Low sodium levels*, indicated by headache, trouble focusing, memory problems, feeling confused, weakness, seizures, or change in balance; any unexplained bruising or bleeding; swelling in arms or legs; muscle cramps. ■ *Signs of an allergic reaction*, indicated by hives; itching, red, swollen, blistered, or peeling sin with or without fever; wheezing; tightness of chest; trouble breathing, swallowing, or talking; unusual hoarseness; or swelling of mouth, face, lips, tongue, or throat.

ANTIDOTE

There is no antidote; stop infusion for hypersensitivity reactions and treat appropriately.

NOREPINEPHRINE BITARTRATE BBW

(**nor**-ep-ih-**NEF**-rin by-**TAR**-trayt)
Levarterenol Bitartrate, Levophed
Vasopressor
pH 3 to 4.5

USUAL DOSE

Weight based:

0.05 to 0.15 mcg/kg/min titrated to desired BP range.

Non–weight based:

5 to 15 mcg/min (based on 80-kg patient) and titrated to BP range.

Larger doses may be given safely as long as the patient remains hypotensive and blood volume depletion is corrected. Up to 30 mcg/min may be required in patients with refractory shock.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established.

Begin with an initial dose of 0.05 to 0.1 mcg/kg/min as a continuous IV infusion. Titrate to desired effect up to a maximum dose of 4 mcg/kg/min. AHA recommends 0.1 to 2 mcg/kg/min in advanced life support.

DOSE ADJUSTMENTS

Lower-end initial doses may be indicated in the elderly based on potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Must be diluted in 250 to 1,000 mL of D5W or D5NS and given as infusion. Final concentration based on fluid volume requirements of the patient. Administration in a dextrose solution reduces loss of potency resulting from oxidation. NS without dextrose is not recommended.

Storage:

Before dilution, store at CRT; protect from light.

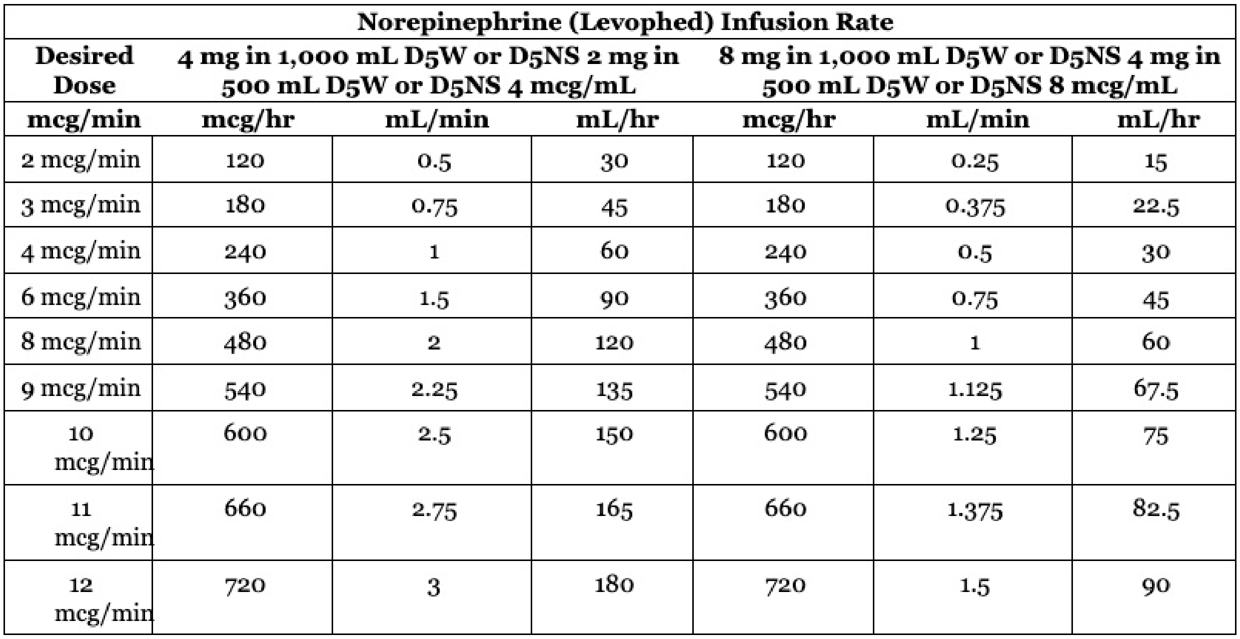
COMPATIBILITY

Consult pharmacist; may be inactivated by solutions with a pH above 6. **Incompatible** with whole blood; administer through **Y-site** or a separate IV line. Avoid contact with iron salts, alkalis, or oxidizing agents.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

See Usual Dose. Use the slowest possible flow rate to correct hypotension gradually and maintain adequate or preset BP. Some response should be noted within 1 to 2 minutes of IV administration. Use of an infusion pump or microdrip (60 gtt/mL) is an aid to correct evaluation of dose. Reduce infusion rate gradually. Avoid sudden discontinuation.



Norepinephrine (Levophed) Infusion Rate						
Desired Dose	4 mg in 1,000 mL D5W or D5NS 2 mg in 500 mL D5W or D5NS 4 mcg/mL			8 mg in 1,000 mL D5W or D5NS 4 mg in 500 mL D5W or D5NS 8 mcg/mL		
mcg/min	mcg/hr	mL/min	mL/hr	mcg/hr	mL/min	mL/hr
2 mcg/min	120	0.5	30	120	0.25	15
3 mcg/min	180	0.75	45	180	0.375	22.5
4 mcg/min	240	1	60	240	0.5	30
6 mcg/min	360	1.5	90	360	0.75	45
8 mcg/min	480	2	120	480	1	60
9 mcg/min	540	2.25	135	540	1.125	67.5
10 mcg/min	600	2.5	150	600	1.25	75
11 mcg/min	660	2.75	165	660	1.375	82.5
12 mcg/min	720	3	180	720	1.5	90

ACTIONS

Levarterenol is the levo-isomer of norepinephrine. It is a sympathomimetic drug that functions as a peripheral vasoconstrictor (alpha-adrenergic action) and inotropic stimulator of the heart and dilator of coronary arteries (beta-adrenergic action). Dilates the coronary arteries more than twice as much as epinephrine can. It is rapidly inactivated in the body by various enzymes and excreted in changed form in the urine.

INDICATIONS AND USES

All hypotensive states, including those associated with spinal anesthesia, blood reactions, drug reactions, hemorrhage, myocardial infarction, pheochromocytomectomy, septicemia, surgery, sympathectomy, and trauma. ■ Adjunct in treatment of cardiac arrest and profound hypotension.

CONTRAINDICATIONS

Do not use in hypotension from blood loss unless an emergency, in mesenteric or peripheral vascular thrombosis, or with cyclopropane or halothane (inhalant) anesthesia.

PRECAUTIONS

Whole blood or plasma should be given in a separate IV site. May be given through Y-tube connection. ■ Use caution in the elderly and in those with peripheral vascular disease or ischemic heart disease. ■ Use caution in previously hypertensive patients; see Monitor. ■ Use caution in patients with allergies; some formulations contain sulfites. ■ Therapy may be continued until the patient can maintain own BP. Decrease dosage gradually.

Monitor:

Check BP every 2 minutes until stabilized at the desired level. Check every 5 minutes thereafter during therapy. Avoid hypertension. One source suggests limiting rise in BP in previously hypertensive patients to no more than 40 mm Hg below previous systolic normal. ■ Observe for hypovolemia and replace fluids immediately. In an emergency, norepinephrine can be effective in a hypovolemic state before fluid replacement has been accomplished. ■ Check flow rate and injection site constantly. ■ Infusion should be through a large vein, preferably the antecubital vein, to prevent complications of prolonged peripheral vasoconstriction. Avoid veins in the hands, ankles, and legs. Use of the femoral vein may be considered. ■ Causes severe tissue necrosis, sloughing, and gangrene. Insert a plastic IV catheter or similar intravascular device at least 6 inches long well into the large vein chosen to prevent extravasation into any surrounding tissue; see Dilution. ■ Blanching along the vein pathway is a preliminary sign of extravasation. Change the injection site. ■ See Drug/Lab Interactions.

Patient Education:

Report IV site burning or stinging promptly. ■ Request assistance to ambulate.

Maternal/Child:

Category C: use only if clearly needed; benefits must outweigh risks. ■ Use caution in breast-feeding.

Elderly:

See Precautions. ■ Lower-end initial doses may be indicated; see Dose Adjustments. ■ Differences in response versus younger patients not documented.

DRUG/LAB INTERACTIONS

Pressor effects may be potentiated by **amphetamines, anesthetics, antihistamines, tricyclic antidepressants, thyroid preparations, and methylphenidate**. ■ May cause severe hypertension with **ergot alkaloids and guanethidine** and severe prolonged hypertension with **MAO inhibitors**. ■ May cause hypotension and bradycardia with **phenytoin**. ■ **Halogenated hydrocarbon anesthetics** (e.g., halothane) may cause serious arrhythmias. ■ Interacts in numerous and sometimes contradictory ways with many drugs.

SIDE EFFECTS

Rare when used as directed; anxiety, arrhythmias (e.g., bradycardia and VT), chest pain, decreased cardiac output, dyspnea, headache, ischemia, necrosis caused by extravasation, pallor, photophobia, seizures, vomiting. Persistent headache may indicate overdose and severe hypertension. Gangrene has been reported.

ANTIDOTE

To prevent sloughing and necrosis in areas where extravasation has occurred, use a fine hypodermic needle to inject 5 to 10 mg of phentolamine (Regitine) diluted in 10 to 15 mL of NS liberally throughout the tissue in the extravasated area. Phentolamine causes immediate and conspicuous local hyperemic changes if the area is infiltrated within 12 hours. Treatment should be started as soon as extravasation is recognized. Atropine may be used to counteract the bradycardia. Notify physician of any side effect. Should a sudden or uncontrolled hypertensive state occur, discontinue levarterenol, notify the physician, and if necessary, treat with an adrenergic blocking agent (e.g., phentolamine or phenoxybenzamine).

USUAL DOSE

Pretreatment:

Prescreening for HBV infection and baseline studies required; see Monitor.

Hypotension may occur during obinutuzumab infusion. Consider withholding antihypertensive medications for 12 hours before and throughout each infusion and for the first hour after administration.

Premedication:

Premedication required. To prevent or attenuate severe hypersensitivity reactions, premedicate according to the following chart before the indicated infusion.

Premedication for Obinutuzumab Infusion to Reduce Infusion-Related Reactions (IRR) in Patients With Chronic Lymphocytic Leukemia (CLL) and Follicular Lymphoma (FL)

Day of Treatment Cycle	Patients Requiring Premedication	Premedication	Administration
Cycle 1: **CLL Day 1 Day 2**	All patients	IV glucocorticoid: Dexamethasone 20 mg **OR** Methylprednisolone 80 mg[a.b]	Completed at least 1 hour before obinutuzumab infusion
FL Day 1		Acetaminophen 650 to 1,000 mg Antihistamine (e.g., diphenhydramine 50 mg)	Administer at least 30 minutes before obinutuzumab infusion
All subsequent infusions	All patients	Acetaminophen 650 to 1,000 mg	Administer at least 30 minutes before obinutuzumab infusion
	Patients with an IRR (≥Grade 1 to 2) with the previous infusion	Acetaminophen 650 to 1,000 mg Antihistamine (e.g., diphenhydramine 50 mg)	Administer at least 30 minutes before obinutuzumab infusion
	Patients with a Grade 3 IRR with the previous infusion **OR** With a lymphocyte count >25,000 cells/mm^3 before next treatment	IV glucocorticoid: Dexamethasone 20 mg **OR** Methylprednisolone 80 mg[a]	Completed at least 1 hour before obinutuzumab infusion
		Acetaminophen 650 to 1,000 mg Antihistamine (e.g., diphenhydramine 50 mg)	Administer at least 30 minutes before obinutuzumab infusion

[a] Hydrocortisone is not recommended. It has not been effective in reducing the rate of infusion reactions.

[b] If a glucocorticoid-containing chemotherapy regimen is administered on the same day as obinutuzumab, the glucocorticoid can be administered as an oral medication if given at least 1 hour before obinutuzumab, in which case additional IV glucocorticoid as premedication is not required.

Tumor lysis syndrome (TLS) prophylaxis:

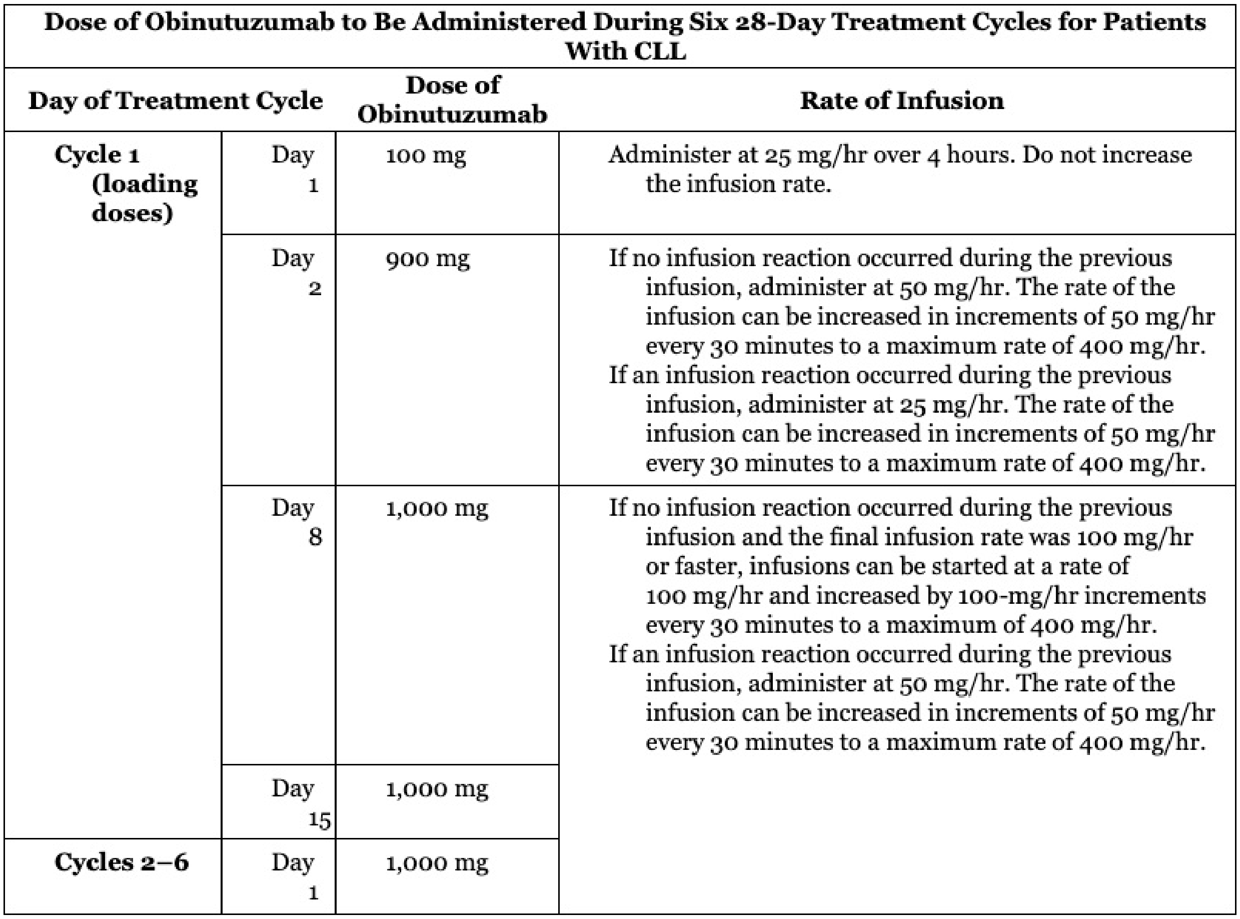
Premedicate patients who have a high tumor burden, high circulating absolute lymphocyte counts (greater than 25,000 cells/mm^3), or renal impairment with antihyperuricemics (e.g., allopurinol or rasburicase) before the start of therapy. Ensure adequate hydration. Continue prophylaxis before each subsequent obinutuzumab infusion as needed.

Antimicrobial prophylaxis:

Strongly recommended for patients with Grade 3 to 4 neutropenia lasting more than 1 week. Prophylaxis should continue until resolution of neutropenia to Grade 1 or 2. Consider antiviral and antifungal prophylaxis.

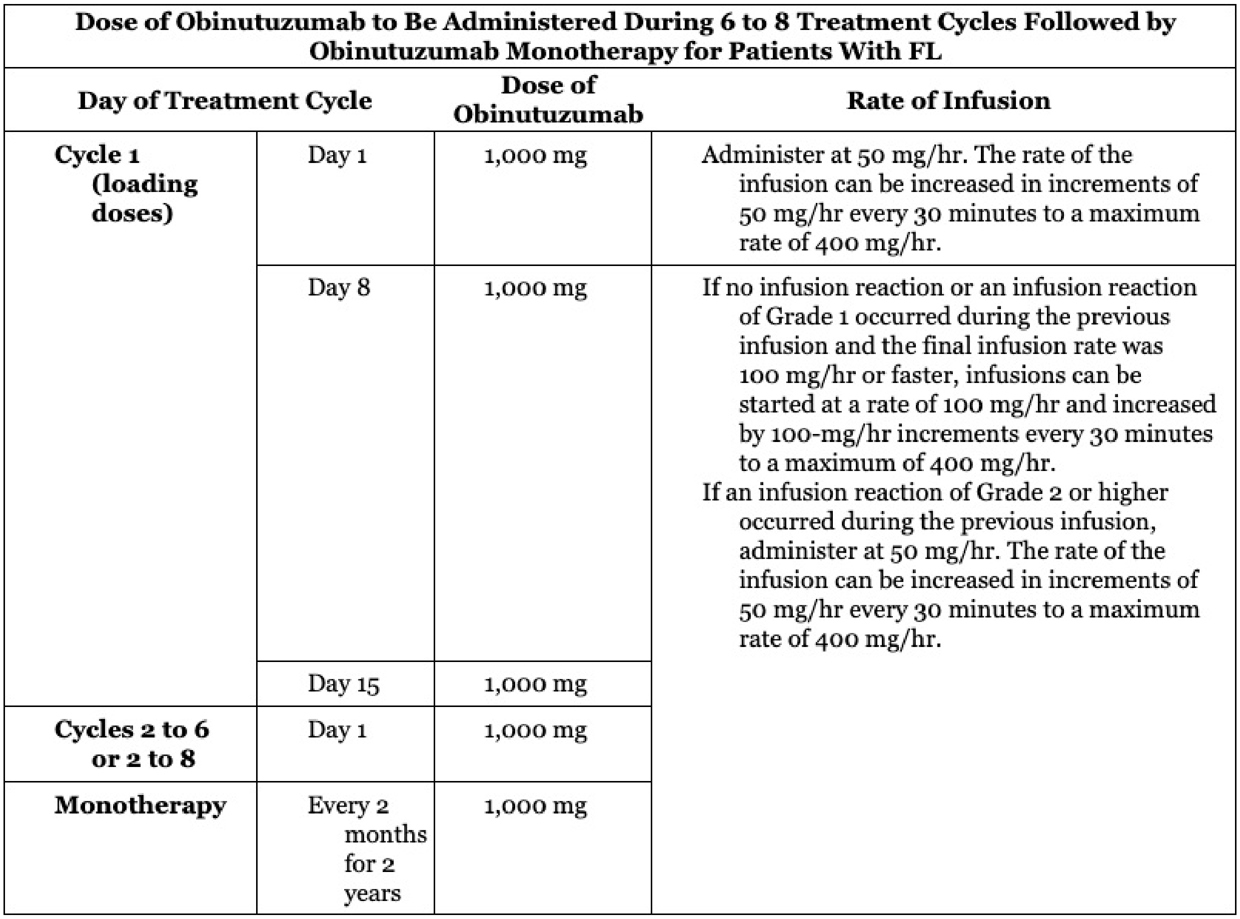
Obinutuzumab:

Doses must be administered as an infusion through a dedicated line according to the following two charts.



Dose of Obinutuzumab to Be Administered During Six 28-Day Treatment Cycles for Patients With CLL

Day of Treatment Cycle		Dose of Obinutuzumab	Rate of Infusion
Cycle 1 (loading doses)	Day 1	100 mg	Administer at 25 mg/hr over 4 hours. Do not increase the infusion rate.
	Day 2	900 mg	If no infusion reaction occurred during the previous infusion, administer at 50 mg/hr. The rate of the infusion can be increased in increments of 50 mg/hr every 30 minutes to a maximum rate of 400 mg/hr. If an infusion reaction occurred during the previous infusion, administer at 25 mg/hr. The rate of the infusion can be increased in increments of 50 mg/hr every 30 minutes to a maximum rate of 400 mg/hr.
	Day 8	1,000 mg	If no infusion reaction occurred during the previous infusion and the final infusion rate was 100 mg/hr or faster, infusions can be started at a rate of 100 mg/hr and increased by 100-mg/hr increments every 30 minutes to a maximum of 400 mg/hr. If an infusion reaction occurred during the previous infusion, administer at 50 mg/hr. The rate of the infusion can be increased in increments of 50 mg/hr every 30 minutes to a maximum rate of 400 mg/hr.
	Day 15	1,000 mg	
Cycles 2–6	Day 1	1,000 mg	



Dose of Obinutuzumab to Be Administered During 6 to 8 Treatment Cycles Followed by Obinutuzumab Monotherapy for Patients With FL

Day of Treatment Cycle		Dose of Obinutuzumab	Rate of Infusion
Cycle 1 (loading doses)	Day 1	1,000 mg	Administer at 50 mg/hr. The rate of the infusion can be increased in increments of 50 mg/hr every 30 minutes to a maximum rate of 400 mg/hr.
	Day 8	1,000 mg	If no infusion reaction or an infusion reaction of Grade 1 occurred during the previous infusion and the final infusion rate was 100 mg/hr or faster, infusions can be started at a rate of 100 mg/hr and increased by 100-mg/hr increments every 30 minutes to a maximum of 400 mg/hr. If an infusion reaction of Grade 2 or higher occurred during the previous infusion, administer at 50 mg/hr. The rate of the infusion can be increased in increments of 50 mg/hr every 30 minutes to a maximum rate of 400 mg/hr.
	Day 15	1,000 mg	
Cycles 2 to 6 or 2 to 8	Day 1	1,000 mg	
Monotherapy	Every 2 months for 2 years	1,000 mg	

Relapsed or refractory FL:

Administer obinutuzumab in combination with bendamustine for six 28-day cycles. Patients who achieve stable disease, complete response, or partial response to the initial 6 cycles should continue obinutuzumab as monotherapy for 2 years.

Previously untreated FL:

Administer obinutuzumab with one of the following chemotherapy regimens:

- Six 28-day cycles in combination with bendamustine
- Six 21-day cycles in combination with CHOP (cyclophosphamide, doxorubicin, vincristine, prednisone) followed by 2 additional 21-day cycles of obinutuzumab alone
- Eight 21-day cycles in combination with CVP (cyclophosphamide, vincristine, prednisone)

Patients with previously untreated FL who achieve a complete response or partial response to the initial 6 or 8 cycles should continue on obinutuzumab as monotherapy for up to 2 years.

DOSE ADJUSTMENTS

Consider treatment interruption if patients experience an infection, Grade 3 or 4 cytopenia, or a Grade 2 or greater nonhematologic toxicity. ■ In patients with Grade 3 or 4 thrombocytopenia, consider a dose delay of obinutuzumab and chemotherapy or a dose reduction of chemotherapy. ■ If a planned dose is missed in patients with CLL, administer the missed dose as soon as possible and adjust the dosing schedule to maintain the time interval between doses. If appropriate, patients who do not complete the Day 1–Cycle 1 dose may proceed to the Day 2–Cycle 1 dose. ■ If a planned dose is missed in patients with FL, administer the missed dose as soon as possible. During obinutuzumab and chemotherapy treatment, adjust the dosing schedule accordingly to maintain the time interval between chemotherapy cycles. During monotherapy, maintain the original dosing schedule for subsequent doses. Monotherapy should be initiated approximately 2 months after the last dose of obinutuzumab administered during the induction phase. ■ No dose adjustment indicated based on age, weight, or baseline CrCl. Has not been studied in patients with hepatic impairment.

DILUTION

Available in a 1,000 mg/40 mL (25 mg/mL) single-use vial. Aseptic technique imperative.

CLL:

Preparation of solution for infusion on Day 1 (100 mg) and Day 2 (900 mg) of Cycle 1:

Withdraw 4 mL (100 mg) of obinutuzumab solution from the vial. Inject into a 100-mL infusion bag of NS for immediate administration. Withdraw the remaining 36 mL (900 mg) of solution from the vial and inject into a 250-mL infusion bag of NS for use on Day 2. Mix infusion bags by gentle inversion. ***Do not shake***. Clearly label each infusion bag; see Storage.

CLL and FL:

Preparation of 1,000-mg dose:

Withdraw 40 mL of obinutuzumab solution from the vial. Inject into a 250-mL infusion bag of NS. Mix by gentle inversion. ***Do not shake or freeze***. Should be used immediately; see Storage. Final concentrations of 0.4 to 4 mg/mL are suitable for administration.

Filters:

Specific information not available.

Storage:

Refrigerate single-use vials at 2° to 8° C (36° to 46° F) in carton to protect from light. ***Do not freeze. Do not shake***. If not used immediately, infusions diluted for use may be refrigerated for up to 24 hours, followed by 48 hours (including infusion time) at RT. Allow to come to room temperature, then use immediately.

COMPATIBILITY

Manufacturer states, “Dilute into a 0.9% sodium chloride (NS) PVC or non-PVC polyolefin infusion bag. ***Do not*** use other diluents such as dextrose (5%),” “Do not mix with other drugs,” “ Administer through a dedicated line,” and “No **incompatibilities** with polyvinylchloride (PVC) or non-PVC polyolefin bags and administration sets have been observed.”

RATE OF ADMINISTRATION

Do not administer as an IV push or bolus. Administer as an IV infusion through a dedicated line; see Usual Dose for specific rates of infusion. If an infusion reaction occurs, adjust the rate as follows.

Grade 1-2 (mild to moderate):

Reduce or interrupt infusion and treat as indicated. With resolution of symptoms, continue or resume infusion. If no further reactions occur, rate may escalate as indicated for each treatment-cycle dose.

Grade 3 (severe):

Interrupt infusion and manage symptoms. With resolution of symptoms, consider restarting the infusion at no more than half the rate that caused the reaction. If no further reactions occur, rate may escalate as indicated for each treatment-cycle dose. Discontinue permanently if a Grade 3 reaction occurs on rechallenge.

Grade 4 (life-threatening):

Stop infusion immediately and discontinue therapy permanently.

ACTIONS

An antineoplastic agent. A humanized anti-CD20 monoclonal antibody of the IgG1 subclass produced by recombinant DNA technology. It targets the CD20 antigen expressed on the surface of pre–B-lymphocytes and mature B-lymphocytes. Upon binding to CD20, it mediates B-cell lysis through several processes, resulting in cell death. Causes CD19 B-cell depletion. Recovery of CD19 B-cells may occur approximately 9 months after the last obinutuzumab dose, but some patients remain depleted at 18 months. Elimination occurs by a linear clearance pathway and a time-dependent nonlinear clearance pathway. Terminal half-life ranges from 25.5 to 35.3 days.

INDICATIONS AND USES

Treatment of adult patients with previously untreated chronic lymphocytic leukemia (CLL) in combination with chlorambucil (Leukeran). ■ Treatment of adult patients with follicular lymphoma (FL) who relapsed after or are refractory to a rituximab-containing regimen. Given in combination with bendamustine followed by obinutuzumab monotherapy. ■ Treatment of adult patients with previously untreated stage II bulky, III, or IV follicular lymphoma (FL) who have achieved at least a partial remission. Given in combination with chemotherapy followed by obinutuzumab monotherapy.

CONTRAINDICATIONS

Known hypersensitivity reaction (e.g., anaphylaxis) to obinutuzumab or any of the excipients. ■ Serum sickness with prior obinutuzumab use.

PRECAUTIONS

For IV infusion only; do not administer as an IV push or bolus. ■ Should be administered by or under the direction of the physician specialist in facilities equipped to monitor the patient and respond to any medical emergency. ■ Hepatitis B virus reactivation with fulminant hepatitis, hepatic failure, and death can occur in patients treated with anti-CD20–directed cytolytic antibodies, including obinutuzumab. For patients who show evidence of hepatitis B infection, consult physician with expertise in managing hepatitis B regarding monitoring and consideration for HBV antiviral therapy; see Monitor. ■ Progressive multifocal leukoencephalopathy (PML), including fatal PML, can occur in patients receiving obinutuzumab. JC virus infection resulting in PML was observed in patients treated with obinutuzumab. ■ Severe and life-threatening infusion reactions have occurred within 24 hours of receiving obinutuzumab and with subsequent infusions. ■ Hypersensitivity reactions have been reported and may present as an immediate-onset hypersensitivity reaction or a late-onset hypersensitivity reaction diagnosed as serum sickness; see Contraindications. ■ Tumor lysis syndrome (TLS) has been reported. May cause acute renal failure requiring dialysis and has been fatal. ■ TLS occurs more often in patients with a high tumor burden, a high circulating lymphocyte count (greater than 25,000/mm^3), or renal impairment. Consider prophylactic measures; see Monitor and Usual Dose. ■ Serious bacterial, fungal, and new or reactivated viral infections can occur during and/or following therapy. Do not administer to patients with an active infection. Patients with a history of recurring or chronic infections may be at increased risk for infection. ■ Severe and life-threatening neutropenia, including febrile neutropenia, has been reported during treatment with obinutuzumab. May be delayed (occurring more than 28 days after completion of treatment and/or prolonged [lasting longer than 28 days]). Anticipate, evaluate, and treat any S/S of developing infection. Consider administration of granulocyte colony-stimulating factors (G-CSF) in patients with Grade 3 or 4 neutropenia. ■ Severe and life-threatening thrombocytopenia has been reported during treatment with obinutuzumab in combination with chemotherapy. Fatal hemorrhagic events have occurred, including during Cycle 1 in patients with CLL being treated with obinutuzumab in combination with chemotherapy. ■ A protein substance; has a potential for immunogenicity. ■ Has not been studied in patients with hepatic impairment. ■ See Drug/Lab Interactions.

Monitor:

Obtain baseline CBC and platelet count and monitor at regular intervals. Repeat more frequently in patients who develop cytopenias (e.g., leukopenia, neutropenia, thrombocytopenia). ■ Screen all patients for HBV infection before treatment initiation. Monitor HBV-positive patients during and after treatment with obinutuzumab. Monitor patients with evidence of current or prior HBV infection for clinical and laboratory signs of hepatitis or HBV reactivation during and for several months after treatment with obinutuzumab. ■ Insufficient data exist regarding the safety of resuming obinutuzumab therapy in patients who develop HBV reactivation; see Antidote. ■ Consider PML in patients with new-onset or changes to pre-existing neurologic manifestations; consultation with a neurologist, brain MRI, and lumbar puncture may be required for diagnosis. ■ Monitor closely for S/S of an infusion reaction (e.g., bronchospasm, chest discomfort, chills, diarrhea, dizziness, dyspnea, fatigue, fever, flushing, headache, hypertension, hypotension, laryngeal edema, larynx and throat irritation, nausea, rash, tachycardia, vomiting, and wheezing). See Antidote for responses to various grades of an infusion reaction. ■ Monitor for S/S of a hypersensitivity reaction. May be difficult to clinically distinguish from an IRR. However, hypersensitivity reactions rarely occur with the first infusion and, when observed, often occur after a previous exposure. S/S of immediate reactions may include bronchospasm, dyspnea, hypotension, tachycardia, and urticaria. S/S of late-onset reactions (serum-sickness) include chest pain, diffuse arthralgia, and fever. ■ Patients with pre-existing cardiac or pulmonary conditions may be at greater risk for severe infusion reactions; monitor closely during and after the infusion. ■ Monitor patients for TLS, especially during the initial days of obinutuzumab treatment. S/S may include rapid reduction in tumor volume, renal insufficiency, hyperkalemia, hypocalcemia, hyperuricemia, or hyperphosphatemia. Prevention and treatment of hyperuricemia due to TLS may be accomplished with adequate hydration and administration of anti-hyperuricemics (e.g., allopurinol or rasburicase); see Usual Dose. Monitor electrolytes, renal function, and fluid status. Correct electrolyte abnormalities and provide supportive care, including dialysis, as indicated. ■ Observe closely for signs of infection. Patients with severe and long-lasting (greater than 1 week) neutropenia are strongly recommended to receive antimicrobial prophylaxis until resolution of neutropenia to Grade 1 or 2. Antiviral and antifungal prophylaxis should also be considered. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3) and hemorrhagic events, especially during the first cycle. In patients with Grade 3 or Grade 4 thrombocytopenia, monitor platelet count more frequently until resolution and consider subsequent dose delays of obinutuzumab and chemotherapy or dose reductions of chemotherapy; see Antidote. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

See Maternal/Child. ■ Discuss health history (e.g., presence of an infection, carrier of or previous infection with hepatitis B virus, recent or scheduled vaccinations) and prescription and nonprescription medications with the health care provider administering the obinutuzumab. ■ Avoid vaccinations with live virus vaccines. ■ Review monitoring requirements and potential side effects before therapy. ■ Promptly report S/S of infection (e.g., fever, cough). ■ Promptly report S/S of infusion reactions, including breathing problems, chest pain, chills, diarrhea, dizziness, fever, nausea, and vomiting. ■ Promptly report S/S of TLS, including diarrhea, lethargy, nausea, and vomiting, and S/S of hepatitis, including worsening fatigue or yellow discoloration of skin or eyes. ■ Promptly report new neurologic S/S (e.g., changes in vision, loss of balance or coordination, disorientation, or confusion); could be warning signs of PML.

■ Patients with a history of hepatitis B infection should be monitored and, if needed, treated for their hepatitis. ■ See Appendix D, p. 1311.

Maternal/Child:

Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. Obinutuzumab is likely to cause fetal B-cell depletion. Avoid administering live vaccines to neonates and infants exposed to obinutuzumab in utero until B-cell recovery occurs. ■ Weigh risk versus benefit when considering breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

In clinical trials, the incidence of serious adverse events was higher in older patients. Effectiveness was similar to that seen in younger adults.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. ■ Avoid vaccinations with live or attenuated virus vaccines. Immunization with live virus vaccines is not recommended during treatment and until B-cell recovery. ■ Consider withholding concomitant medications that may increase the risk of bleeding (e.g., platelet inhibitors, anticoagulants), especially during the first cycle. ■ Hypotension may occur during obinutuzumab infusion. Consider withholding antihypertensive medications for 12 hours before and throughout each infusion and for the first hour after administration.

SIDE EFFECTS

Anemia, cough, diarrhea, fever, infusion reactions, nausea, neutropenia, and thrombocytopenia are the most commonly reported adverse reactions in patients with CLL or FL. Alopecia, arthralgia, asthenia, constipation, decreased appetite, fatigue, headache, herpes virus infection, insomnia, pneumonia, pruritus, sinusitis, upper respiratory tract infections, urinary tract infections, and vomiting were also commonly reported in patients with FL. Infusion reactions may be life-threatening. Hepatitis B reactivation, PML, serious infections, and tumor lysis syndrome have all been reported and may be life threatening. Back pain; dyspepsia; fatal hemorrhagic events (first cycle); hyperkalemia; hypernatremia; hypersensitivity reactions; hyperuricemia; hypoalbuminemia; hypocalcemia; hypokalemia; hyponatremia; hypophosphatemia; hypoproteinemia; increased ALT, AST, alkaline phosphatase, and creatinine; leukopenia; lymphopenia; nasal congestion; nasopharyngitis; pain in extremities; and worsening of pre-existing cardiac conditions have also been reported.

Post-Marketing:

Serum sickness.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Interrupt or reduce rate of infusion for Grade 1 or 2 infusion reactions and manage symptoms. Interrupt therapy for Grade 3 infusion reactions until resolution of symptoms. Permanently discontinue therapy for any Grade 4 infusion reaction including, but not limited to, anaphylaxis. Severe infusion reactions may require epinephrine, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., dexamethasone), oxygen or bronchodilators (e.g., albuterol). Maintain a patent airway. In patients who have a Grade 1, 2, or 3 infusion reaction, see Rate of Administration for rate adjustments required if treatment is to be continued. If a hypersensitivity reaction is suspected during or after an infusion, the infusion must be stopped and treatment permanently discontinued. In patients who develop reactivation of HBV, immediately discontinue obinutuzumab and concomitant chemotherapy and institute appropriate treatment. Resumption of therapy should be discussed with physicians with expertise in managing hepatitis B. Discontinue obinutuzumab and consider discontinuation or reduction of concomitant chemotherapy or immunosuppressive therapy in patients who develop PML. Consider treatment interruption in the event of infection, Grade 3 or 4 cytopenia, or a hematologic toxicity equal to or greater than Grade 2. Dose delays of obinutuzumab and chemotherapy or dose reductions of chemotherapy may be indicated. Consider administration of granulocyte colony-stimulating factors (G-CSF) in patients with Grade 3 or 4 neutropenia. Tumor lysis syndrome requires correction of electrolyte abnormalities and monitoring of renal function and fluid balance. Supportive care, including dialysis, may be required. Thrombocytopenia may require transfusion of blood products (i.e., platelet transfusion). Resuscitate as indicated.

OBILTOXAXIMAB BBW

(oh-bil-tox-**AX**-i-mab)
Anthim
Monoclonal antibody
pH 5.5

USUAL DOSE

Premedication:

Administer diphenhydramine before infusing obiltoxaximab. Although it does not prevent anaphylaxis, it may decrease the occurrence of other reported adverse reactions.

Obiltoxaximab:

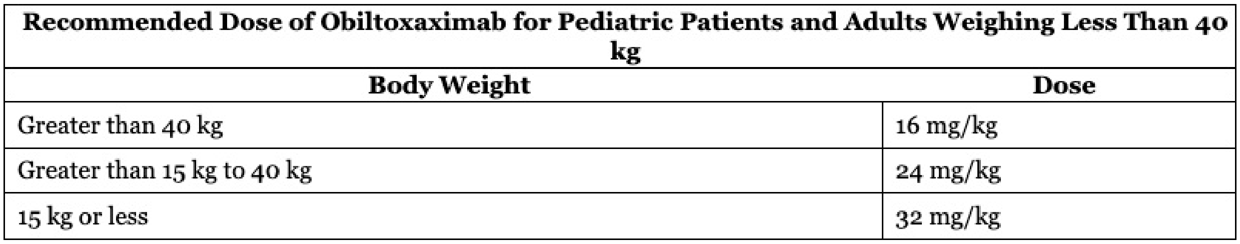
A single dose of 16 mg/kg administered as an infusion over 90 minutes. See chart in Pediatric Dose for adults weighing less than 40 kg.

PEDIATRIC DOSE

Premedication:

See Usual Dose.

See the following chart for recommended weight-based dosing.



Recommended Dose of Obiltoxaximab for Pediatric Patients and Adults Weighing Less Than 40 kg	
Body Weight	**Dose**
Greater than 40 kg	16 mg/kg
Greater than 15 kg to 40 kg	24 mg/kg
15 kg or less	32 mg/kg

DOSE ADJUSTMENTS

Age, gender, and race have no meaningful effect on the pharmacokinetics of obiltoxaximab.

DILUTION

Available in single-dose vials containing 600 mg/6 mL (100 mg/mL). A clear to opalescent, colorless to pale yellow to pale brownish-yellow solution that may contain a few translucent-to white proteinaceous particulates. ***Do not shake.*** Sterile technique imperative; contains no preservatives. Obiltoxaximab solution must be diluted with NS in an appropriately sized infusion bag or syringe depending on the total volume required. Calculate the required dose:

Suggested dose × Patient weight (kg) = Required dose (mg)

Then calculate the required volume:

Calculated dose (mg) ÷ Concentration (100 mg/mL) = Required volume of obiltoxaximab (mL)

Infusion bag:

Withdraw a volume of solution from the infusion bag of NS equal to the calculated volume in mL of obiltoxaximab. Transfer the required volume (dose) of obiltoxaximab to the selected infusion bag. Gently invert the bag to mix the solution. ***Do not shake.***

Syringe:

Using an appropriately sized syringe for the total volume of infusion to be administered, withdraw the calculated volume (dose) of obiltoxaximab into the syringe, then withdraw the appropriate amount of NS into the syringe. Gently mix the solution. ***Do not shake.***

See the following chart for recommended dose, total infusion volume, and infusion rate by body weight.

Obiltoxaximab Dose, Total Infusion Volume, and Infusion Rate by Body Weight		
Body Weight (Weight-Based Dosing)	**Total Infusion Volume**	**Infusion Rate**
Weight Greater Than 40 kg or Adult (16 mg/kg)		
Greater than 40 kg	250 mL	167 mL/hr
Weight Greater Than 15 kg to 40 kg (24 mg/kg)		
31 to 40 kg	250 mL	167 mL/hr
16 to 30 kg	100 mL	67 mL/hr
Weight 15 kg or Less (32 mg/kg)		
11 to 15 kg	100 mL	67 mL/hr
5 to 10 kg	50 mL	33.3 mL/hr
3.1 to 4.9 kg	25 mL	17 mL/hr
2.1 to 3 kg	20 mL	13.3 mL/hr
1.1 to 2 kg	15 mL	10 mL/hr
1 kg or less	7 mL	4.7 mL/hr

Filters:

Use of a 0.22-micron in-line filter is required for administration.

Storage:

Before use, refrigerate at 2° to 8° C (36° to 46° F) in original carton to protect from light. Do not freeze. Do not shake. ***Infusion bag:*** Prepared solution stable for 4 hours at RT or refrigerated. Discard NS withdrawn from bag and discard unused portion in obiltoxaximab vials. ***Syringe:*** Administer immediately. Do not store solution in syringe. Discard unused product.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer through a 0.22-micron in-line filter.

A single dose as an infusion over 90 minutes. See chart in Dilution for recommended total infusion volumes and infusion rates for weight-based dosing. Flush the IV line with NS after the infusion.

ACTIONS

A chimeric IgG1 kappa monoclonal antibody (mAb) that binds the protective antigen (PA) component of *Bacillus anthracis* toxin. It inhibits the binding of PA to its cellular receptors, thereby preventing the intracellular entry of the anthrax lethal factor and edema factor, the enzymatic toxin components responsible for the pathogenic effects of anthrax toxin. Steady-state volume of distribution is greater than plasma volume, suggesting some tissue distribution. Virtually no renal clearance occurs.

INDICATIONS AND USES

Treatment of inhalational anthrax due to *B. anthracis* in adult and pediatric patients. Used in combination with appropriate antibacterial drugs (e.g., ciprofloxacin [Cipro], doxycycline, levofloxacin [Levaquin]). ■ Prophylaxis of inhalational anthrax due to *B. anthracis* when alternative therapies are not available or are not appropriate.

Limitations of use:

Should be used only for prophylaxis when its benefit for prevention of inhalational anthrax outweighs the risk of hypersensitivity and anaphylaxis. ■ Effectiveness is based solely on efficacy studies in animal models of inhalational anthrax. ■ No studies of the safety or pharmacokinetics (PK) have been done in the pediatric population. Dosing in pediatric patients was derived using a population pharmacokinetics approach designed to match the observed adult exposure to obiltoxaximab at a 16 mg/kg dose. ■ Does not have direct antibacterial activity. Should be used in combination with appropriate antibacterial drugs. ■ Not expected to cross the blood-brain barrier and does not prevent or treat meningitis.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For IV use only. ■ Administered by or under the direction of a physician knowledgeable in its use and in a facility equipped to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. ■ A therapeutic protein, there is a potential for immunogenicity.

Monitor:

Monitor for S/S of a hypersensitivity reaction (e.g., chest discomfort, cough, cyanosis, dyspnea, hypotension, postural dizziness, pruritus, rash, throat irritation, urticaria, wheezing) during the infusion and for some time following completion of the infusion. Reactions have occurred both during and after the infusion. ■ Premedication with diphenhydramine does not prevent anaphylaxis and may mask or delay the onset of symptoms of hypersensitivity.

Patient Education:

Effectiveness has been studied only in animals with inhalational anthrax. ■ Immediately report any S/S of a hypersensitivity reaction (e.g., chest discomfort, cough, cyanosis, dyspnea, hypotension, postural dizziness, pruritus, rash, throat irritation, urticaria, wheezing) occurring during or after administration.

Maternal/Child:

No data on the use of obiltoxaximab in pregnant women to inform on drug-associated risk. Maternal infection with anthrax is associated with a high risk of maternal, fetal, and neonatal deaths, particularly in the absence of treatment. ■ No information on the presence of obiltoxaximab in human milk, effects on the breast-fed infant, or the effects on milk production. Maternal IgG is known to be present in human milk; consider benefits versus risk. ■ Safety and effectiveness for use in pediatric patients is based solely on efficacy studies in animal models; see Limitations of Use.

Elderly:

Numbers in clinical studies are insufficient to determine whether the elderly respond differently than younger subjects.

DRUG/LAB INTERACTIONS

Coadministration of 16 mg/kg obiltoxaximab IV with IV or oral ciprofloxacin did not alter the pharmacokinetics of either ciprofloxacin or obiltoxaximab.

SIDE EFFECTS

The most frequently reported side effects in adults were cough, headache, infections of the upper respiratory tract, infusion site pain and/or swelling, nasal congestion, pain in extremity, pruritus, urticaria, and vessel puncture site bruising. Hypersensitivity reactions are the most serious side effect.

ANTIDOTE

Keep the physician informed of all side effects. Most will be treated symptomatically. If a hypersensitivity reaction occurs, discontinue the infusion immediately and treat with oxygen, epinephrine, antihistamines (e.g., IV diphenhydramine), corticosteroids, albuterol, vasopressors (e.g., dopamine), and ventilation equipment as indicated. No clinical experience with overdose. If overdose occurs, monitor patients for S/S of adverse effects. Resuscitate as necessary.

OCRELIZUMAB

Ocrevus
Monoclonal antibody
(Anti-CD20 monoclonal antibody)
pH 5.3

USUAL DOSE

Pretreatment:

Verify pregnancy status. Preassessment required; see Monitor.

Premedication:

To reduce the incidence and severity of infusion-related reactions, premedicate with ***methylprednisolone*** 100 mg IV (or equivalent steroid) 30 minutes before each ocrelizumab infusion. Premedicate with an ***antihistamine*** (e.g., diphenhydramine) approximately 30 to 60 minutes before the infusion to further reduce the frequency and severity of infusion reactions. Administration of an ***antipyretic*** (e.g., acetaminophen) may also be considered.

Ocrelizumab:

Initial dose: 300 mg as an IV infusion followed 2 weeks later by a second 300-mg IV infusion. ***Subsequent doses:*** 600 mg as an IV infusion every 6 months. The recommended dose, infusion rate, and infusion duration for ocrelizumab are outlined in the following chart.

Recommended Dose, Infusion Rate, and Infusion Duration of Ocrelizumab for Relapsing or Primary Progressive Multiple Sclerosis

		Amount and Volume	Infusion Rate and Duration[a]
Initial Dose (two infusions)	Infusion 1	300 mg in 250 mL	Start at 30 mL/hr Increase by 30 mL/hr every 30 minutes Maximum: 180 mL/hr Duration: 2.5 hr or longer
	Infusion 2 (2 weeks later)	300 mg in 250 mL	
Subsequent Doses (one infusion)	One infusion every 6 months[b]	600 mg in 500 mL	Start at 40 mL/hr Increase by 40 mL/hr every 30 minutes Maximum: 200 mL/hr Duration: 3.5 hr or longer

[a] Infusion time may take longer if the infusion is interrupted or slowed.

[b] Administer the first subsequent dose 6 months after Infusion 1 of the initial dose.

DOSE ADJUSTMENTS

If a planned dose is missed, administer as soon as possible; do not wait until the next scheduled dose. Reset the dose schedule to administer the next sequential dose 6 months after the missed dose. Doses of ocrelizumab must be separated by at least 5 months. ■ For mild to moderate infusion reactions, reduce the infusion rate to half the rate at the onset of the infusion reaction, and maintain the reduced rate for at least 30 minutes. If this rate is tolerated, increase the rate as described in the previous chart. ■ For severe infusion reactions, immediately interrupt the infusion and administer appropriate supportive treatment as necessary; see Antidote. Restart the infusion only after all symptoms have resolved. When restarting, begin at half of the infusion rate at the time of onset of the infusion reaction. If this rate is tolerated, increase the rate as described in the previous chart. ■ For life-threatening infusion reactions, immediately stop and permanently discontinue ocrelizumab. Provide appropriate supportive treatment; see Antidote.

DILUTION

Available in a 300-mg/10 mL (30-mg/mL) single-dose vial. Solution is clear or slightly opalescent and colorless to pale brown. For initial doses, withdraw 300 mg (10 mL) and inject into 250 mL of NS. For subsequent doses, withdraw 600 mg (20 mL) and inject into 500 mL of NS. Mix gently. ***Do not shake.*** Contents of the infusion bag should be at RT before the start of the IV infusion.

Filter:

Administration through a 0.2- or 0.22-micron in-line filter is required.

Storage:

Store vials at 2° to 8° C (36° to 46° F) in the outer carton to protect from light. Do not freeze or shake. Immediate use of prepared solution is preferred. If not used immediately, may store up to 24 hours in the refrigerator and 8 hours at RT, which includes infusion time. If an IV infusion cannot be completed on the same day, discard the remaining solution.

COMPATIBILITY

Manufacturer states, “Do not use other diluents to dilute ocrelizumab since their use has not been tested. No **incompatibilities** between ocrelizumab and polyvinyl chloride or polyolefin bags and IV administration sets have been observed.”

RATE OF ADMINISTRATION

Use of a 0.2- or 0.22-micron in-line filter required. See chart in Usual Dose for recommended rate of administration.

ACTIONS

A recombinant humanized monoclonal antibody directed against CD20-expressing B-cells. The precise mechanism by which ocrelizumab exerts its therapeutic effects in multiple sclerosis is unknown but is presumed to involve binding to CD20, a cell surface antigen present on pre-B and mature B-lymphocytes. Following cell surface binding to B-lymphocytes, ocrelizumab results in antibody-dependent cellular cytolysis and complement-mediated lysis. CD19+ B-cell counts are reduced in the blood within 14 days of ocrelizumab administration. In one clinical study, the median time for B-cell counts to return to either baseline or the lower limit of normal was 72 weeks. The pharmacokinetics of ocrelizumab is essentially linear and dose proportional between 400 and 2000 mg. Terminal elimination half-life is 26 days.

INDICATIONS AND USES

Treatment of adult patients with relapsing forms of multiple sclerosis, including clinically isolated syndrome, relapsing-remitting disease, and active secondary progressive disease. ■ Treatment of adult patients with primary progressive multiple sclerosis.

CONTRAINDICATIONS

Active hepatitis B virus (HBV) infection. ■ A history of life-threatening infusion reaction to ocrelizumab.

PRECAUTIONS

Ocrelizumab should be administered by or under the direction of the physician specialist in facilities equipped to monitor the patient and respond to any medical emergency. ■ Ocrelizumab can cause infusion reactions that include bronchospasm, dizziness, dyspnea, erythema, fatigue, fever, flushing, headache, hypotension, nausea, oropharyngeal pain, pharyngeal or laryngeal edema, pruritus, rash, tachycardia, throat irritation, and urticaria. Incidence of reactions was highest with the first infusion and may occur despite premedication; see Monitor and Antidote. ■ In clinical trials, a higher proportion of ocrelizumab-treated patients experienced infections compared with patients taking Rebif (interferon beta-1a) or placebo. Infections included upper respiratory tract infections, lower respiratory tract infections, skin infections, and herpes-related infections. However, ocrelizumab was not associated with an increased risk of serious infections in MS patients. Delay ocrelizumab administration in patients with an active infection until the infection has resolved; see Monitor. ■ Progressive multifocal leukoencephalopathy (PML) is an opportunistic viral infection of the brain caused by the JC virus. It is a rare, progressive, demyelinating disease of the CNS that usually leads to death or severe disability, and there is no effective treatment. Although no cases of PML were identified in ocrelizumab trials, JC virus infection resulting in PML has been observed in patients treated with other anti-CD20 antibodies and other MS therapies and has been associated with some risk factors (e.g., immunocompromised patients, polytherapy with immunosuppressants). ■ There have been no reports of hepatitis B reactivation in MS patients treated with ocrelizumab, but fulminant hepatitis B, hepatic failure, and death caused by HBV reactivation have occurred in patients treated with other anti-CD20 antibodies; see Contraindications and Monitor. ■ Vaccination with live-attenuated or live vaccines is not recommended during treatment with ocrelizumab or after discontinuation of ocrelizumab until B-cell repletion; see Monitor. ■ An increased risk of malignancy, including breast cancer, may exist with ocrelizumab therapy. In controlled trials, breast cancer occurred more frequently in ocrelizumab-treated patients. ■ A protein substance; potential for immunogenicity exists. ■ See Drug/Lab Interactions.

Monitor:

Review vaccination status. Complete any required live or live-attenuated vaccinations at least 4 weeks and, whenever possible, non-live vaccinations at least 2 weeks before beginning therapy with ocrelizumab. ■ Screen all patients for HBV infection before treatment initiation; see Contraindications. Consult a liver disease specialist for patients who are negative for surface antigen [HBsAg] and positive for HB core antibody [HBcAb+] or who are carriers of HBV [HBsAg+]. ■ Assess patient for any S/S of an active infection before every infusion. Delay therapy in the presence of an active infection until the infection resolves. ■ Monitor patient during and for at least 1 hour after completion of the infusion for any S/S of an infusion reaction. ■ Assess neurologic status frequently. Consider PML in patients with new-onset neurologic manifestations. At the first S/S suggestive of PML, withhold ocrelizumab and perform an appropriate diagnostic evaluation; consultation with a neurologist, brain MRI, and lumbar puncture may be required for diagnosis. ■ Follow standard breast cancer screening guidelines.

Patient Education:

Read FDA-approved medication guide. ■ Avoid pregnancy; women of childbearing age should use effective birth control during treatment and for 6 months after completion of treatment. ■ Promptly report any S/S of an infusion reaction. Reactions can occur up to 24 hours after the infusion. ■ Promptly report any S/S of infection (e.g., fever, chills, constant cough, or signs of herpes such as cold sores, shingles, or genital sores). ■ New neurologic S/S (e.g., changes in vision, loss of balance or coordination, disorientation, or confusion) could be warning signs of PML. Report them promptly. ■ May cause reactivation of HBV infection. Monitoring may be required in patients at risk. ■ Discuss vaccination status with physician. Complete any required live or live-attenuated vaccinations at least 4 weeks and, whenever possible, non-live vaccinations at least 2 weeks before beginning therapy with ocrelizumab. ■ An increased risk of malignancy, including breast cancer, may exist. Follow standard breast cancer screening guidelines.

Maternal/Child:

Information on the developmental risk associated with the use of ocrelizumab in pregnant women is not available. However, transient peripheral B-cell depletion and lymphocytopenia have been reported in infants born to mothers exposed to other anti-CD-20 antibodies during pregnancy. Ocrelizumab is a humanized monoclonal antibody of an IGG1 subtype, and immunoglobulins are known to cross the placental barrier.■ Use caution if breast-feeding; weigh risk versus benefit. ■ Safety and effectiveness for use in pediatric patients not established. ■ In infants of mothers exposed to ocrelizumab during pregnancy, do not administer live or live-attenuated vaccinations before confirming recovery of B-cell counts as measured by CD19+ B-cells. Administration of non-live vaccines may be completed before B-cell recovery, but consultation with a qualified specialist to assess whether a protective immune response was mounted should be considered.

Elderly:

Clinical trials did not include sufficient numbers of subjects 65 years of age or older to determine whether they respond differently than do younger subjects.

DRUG/LAB INTERACTIONS

When initiating ocrelizumab after an immunosuppressive therapy or when initiating an immunosuppressive therapy after ocrelizumab, consider the potential for increased immunosuppressive effects. The concomitant use of ocrelizumab and other **immune-modulating or immunosuppressive therapies**, including immunosuppressant doses of **corticosteroids,** is expected to increase the risk of immunosuppression; consider the risk of additive immune system effects. ■ The safety of immunization with **live or live-attenuated vaccines** following ocrelizumab therapy has not been studied and is not recommended during treatment and until B-cell repletion; see Monitor. ■ An attenuated antibody response was seen with concomitant use of ocrelizumab and several **non-live vaccines**. The impact of the observed attenuation on vaccine effectiveness is unknown; see Monitor.

SIDE EFFECTS

The most common adverse reactions were infusion reactions, respiratory tract infections (lower and upper), and skin infections. Other frequently reported reactions included back pain, cough, decreased total immunoglobulin (with the greatest decline seen in IgM levels), decreased neutrophil counts, depression, diarrhea, herpes-associated infections, pain in extremities, and peripheral edema.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. For life-threatening infusion reactions, immediately and permanently stop ocrelizumab and administer appropriate supportive treatment. For less severe infusion reactions, management may involve temporarily stopping the infusion, reducing the infusion rate, and/or administering symptomatic treatment (e.g., IV saline, diphenhydramine, bronchodilators such as albuterol, and acetaminophen). Resuscitate if indicated.

OCTREOTIDE ACETATE

(ok-**TREE**-oh-tide **AS**-ah-tayt)
Octreotide Acetate PF, Sandostatin
Antidiarrheal
Growth hormone suppressant
pH 3.9 to 4.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Usually given SC. Check label and confirm for IV use; Sandostatin LAR Depot is for IM use only; see Precautions. In most situations begin with a lower dose to allow gradual tolerance to GI side effects. Increase gradually based on patient response and tolerance. Begin SC or IM (LAR Depot) dosing as soon as practical.

Growth hormone suppression (acromegaly):

50 mcg every 8 hours is the initial dose. Increase dose gradually as indicated by IGF-1 levels; see Monitor. The dose most commonly found to be effective is 100 mcg 3 times daily, but some patients require up to 500 mcg 3 times daily for maximum effectiveness.

Carcinoid tumors:

100 to 600 mcg/24 hr in equally divided doses 2 to 4 times daily during first 2 weeks of therapy (50 to 300 mcg every 12 hours or 25 to 150 mcg every 6 hours). Average total daily dose is 300 mcg. In clinical studies, the median daily maintenance dose was approximately 450 mcg, but therapeutic response was obtained with ranges from 50 to 750 mcg. Up to 1,500 mcg/day has been used in selected patients. Experience with doses above 750 mcg/day is limited.

Vasoactive intestinal peptide tumors:

200 to 300 mcg/24 hr in equally divided doses 2 to 4 times daily during the first 2 weeks of therapy (100 to 150 mcg every 12 hours or 50 to 75 mcg every 6 hours). Therapeutic response is usually achieved with doses at or under 450 mcg/24 hr.

Carcinoid crisis (unlabeled):

500 to 1,000 mcg as an IV bolus. May be given to treat carcinoid crisis during surgery or given before induction of anesthesia as a prophylactic measure. If required intraoperatively, may repeat bolus every 5 minutes as needed to control symptoms. Alternatively, a bolus of 500 to 1,000 mcg may be followed by 50 to 200 mcg/hr as a continuous infusion.

Treatment of esophageal varices bleeding (unlabeled):

Begin with a loading dose of 50 to 100 mcg. Follow with a continuous infusion of 25 to 50 mcg/hr for 2 to 5 days.

PEDIATRIC DOSE

Experience is limited, and doses are **unlabeled.** See Maternal/Child.

Intractable diarrhea:

1 to 10 mcg/kg of body weight every 12 hours. Dose may be increased within the recommended range by 0.3 mcg/kg/dose every 3 days as needed. Maximum dose is 1,500 mcg/24 hr.

DOSE ADJUSTMENTS

In all situations dose adjustment may be required on a daily basis to maintain symptomatic control. After initial 2 weeks of therapy, gradually decrease dose to achieve therapeutically effective maintenance dose. ■ Dose reduction may be required in the elderly; half-life extended and clearance decreased. Start at the lower end of the dosing range. Consider the greater frequency of decreased organ function and of concomitant disease or drug therapy. ■ Half-life markedly extended in severe renal failure requiring dialysis. Reduction of maintenance dose may be indicated. ■ See Drug/Lab Interactions.

DILUTION

Available in several different concentrations and formulations; read label carefully. May be given undiluted or may be diluted with 50 to 200 mL of NS or D5W and given as an intermittent infusion or further diluted and given as a continuous infusion.

Storage:

Before use store in refrigerator (2° to 8° C [36° to 46° F]) or at CRT for 14 days; protect from light. May store at room temperature on day of use. Diluted solution stable for 24 hours. Multidose vial must be dated on opening and discarded after 14 days.

COMPATIBILITY

Manufacturer lists TPN as **incompatible** (forms a conjugate that decreases effectiveness). If used as an additive with insulin, octreotide markedly increases adsorption of insulin and reduces insulin availability.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

A single dose over 3 minutes.

Intermittent infusion:

A single dose over 15 to 30 minutes.

Continuous infusion:

Give at a rate consistent with the required hourly dose in an amount of fluid appropriate for the specific patient.

ACTIONS

A long-acting octapeptide. Mimics the actions of the natural hormone somatostatin, suppressing secretion of serotonin, gastroenteropancreatic peptides (e.g., gastrin, vasoactive intestinal peptide, insulin, glucagon, secretin, motilin, pancreatic polypeptide), and growth hormone. Decreases splanchnic blood flow. Stimulates fluid and electrolyte absorption from GI tract and prolongs GI transit time. These pharmacologic actions provide a means of treating the symptoms associated with metastatic carcinoid tumors (flushing and diarrhea) and vasoactive intestinal peptide (VIP)–secreting tumors (watery diarrhea). Other actions include inhibition of gallbladder contractility and bile secretion and suppression of thyroid-stimulating hormone (TSH) secretion. Distribution from plasma is rapid. About 65% bound to plasma protein. Half-life longer than the natural hormone (1.7 to 1.9 hours compared with 1 to 3 minutes). Action may extend to 12 hours. Some excreted unchanged in urine.

INDICATIONS AND USES

To suppress or inhibit the severe diarrhea and flushing episodes associated with carcinoid tumor. ■ Treatment of profuse watery diarrhea associated with vasoactive intestinal peptide tumors (VIPomas). ■ Treatment of acromegaly to suppress growth hormone and achieve normalization of growth hormone and somatomedin C (IGF-1) levels.

Unlabeled uses:

Treatment of severe diarrhea in patients with AIDS. ■ Treatment of refractory or severe chemotherapy-induced diarrhea. ■ Carcinoid crisis during anesthesia. ■ Adjunct to treatment of sulfonylurea-induced hypoglycemia. ■ Treatment of gastroesophageal variceal bleeding. ■ Diarrhea associated with graft versus host disease.

CONTRAINDICATIONS

Sensitivity to octreotide acetate or any of its components.

PRECAUTIONS

IV use is limited to emergency situations. SC injection with rotation of injection sites is preferred route of administration. ■ Sandostatin LAR Depot must be administered intragluteally but has the advantage of extending the interval between injections to every 4 weeks. ■ May decrease size of tumors and slow rate of growth and metastases. Data not definitive. ■ May inhibit gallbladder contractility and decrease bile secretion. Incidence of gallstone or biliary sludge formation was markedly increased in clinical trials. Cholelithiasis resulting in complications requiring cholecystectomy have been reported. ■ Use caution in patients with diabetes. In patients with Type 1 diabetes, octreotide is likely to affect glucose regulation, and insulin requirements may be decreased. Severe, symptomatic hypoglycemia has been reported. In nondiabetics and Type 2 diabetics with partially intact insulin reserves, octreotide may result in decreased insulin levels and hyperglycemia. Glucose tolerance and antidiabetic treatment should be closely monitored. ■ Cardiac abnormalities (e.g., arrhythmias, bradycardia, conduction abnormalities, QT prolongation) have been reported. More common in patients with acromegaly; see Side Effects. ■ Suppresses thyroid-stimulating hormone. May cause hypothyroidism. ■ Pancreatitis has been reported. Octreotide may alter the absorption of dietary fats in some patients. ■ Depressed B_{12} levels and abnormal Schilling's tests have been observed.

Monitor:

Monitor baseline and periodic thyroid function tests (TSH, total, and/or free T_4), especially in long-term SC therapy. ■ Monitor fluids and electrolytes carefully. ■ Observe for transient hyperglycemia or hypoglycemia during induction and dose changes because of changes in balance of hormones (e.g., insulin, glucagon, and growth hormone). ■ 5-HIAA, plasma serotonin, and plasma substance P may be useful lab studies to evaluate patient response with carcinoid tumor. ■ Measurement of plasma vasoactive intestinal peptide will be helpful in VIPoma. ■ In acromegaly, response may be monitored with growth hormone levels at 1- to 4-hour intervals for 8 to 12 hours after a dose. IGF-1 levels every 2 weeks and/or multiple growth hormone levels taken 0 to 8 hours after administration may be used to make dose adjustments. Goal is to achieve growth hormone levels less than 5 ng/mL or IGF-1 levels less than 1.9 units/mL in males and less than 2.2 units/mL in females. After stabilization, IGF-1 or growth hormone levels should be re-evaluated at 6-month intervals. ■ In patients with acromegaly who have received irradiation, octreotide should be withdrawn yearly for 4 weeks to assess disease activity. If growth hormone or IGF-1 levels increase and S/S recur, octreotide therapy should be resumed. ■ Can alter fat absorption and decrease gallbladder motility. Monitor for gallbladder disease. GI symptoms are usually present but may not be specific for gallbladder disease. Ultrasound of gallbladder and bile ducts may be indicated in patients with S/S of gallbladder disease. ■ Monitor for S/S of pancreatitis. ■ Monitor B_{12} levels in prolonged therapy. ■ See Dose Adjustments and Drug/Lab Interactions.

Patient Education:

Instruct patient and/or family in appropriate skills if self-administration indicated. ■ In women with acromegaly being treated with octreotide, normalization of GH and IGF-1 may restore fertility. Effective contraception is recommended. ■ Contact health care provider for experience of S/S of gallstones (e.g., upper right abdominal pain, jaundice, dark urine, clay-colored stools, severe nausea or vomiting).

Maternal/Child:

Although studies do not indicate harm to the fetus or infants, use in pregnancy and breast-feeding only if clearly needed. ■ Safety and effectiveness for use in pediatric patients not established; see Literature. In post-marketing reports, hypoxia, necrotizing enterocolitis, and death have been reported, most notably in pediatric patients under 2 years of age, many of which had serious underlying comorbid conditions. Relationship to octreotide not established.

Elderly:

See Dose Adjustments. ■ Response similar to that seen in younger patients; however, may be more sensitive to side effects; observe carefully.

DRUG/LAB INTERACTIONS

Use caution in patients receiving concomitant **beta-blockers, calcium channel blockers, insulin, oral hypoglycemic agents, or any agents used for fluid and electrolyte balance**. Dose adjustments may be necessary. ■ May affect absorption of **orally administered medications**. ■ May inhibit effectiveness of **cyclosporine** and may result in transplant rejection. ■ May increase availability of **bromocriptine**. ■ Suppression of growth hormones may cause a decreased clearance of drugs metabolized by selected cytochrome P_{450} enzymes. Use caution with concurrent use of **drugs metabolized by CYP3A4** (e.g., HMG-CoA reductase inhibitors, itraconazole, oral midazolam, quinidine).

SIDE EFFECTS

Most side effects are of mild to moderate severity and of short duration. Abdominal pain/discomfort, abnormal stools, backache, blurred vision, bruising, cold and flu symptoms, constipation, depression, diarrhea, dizziness, edema, fat malabsorption, fatigue, flatulence, flushing, gallbladder abnormalities (stones and/or biliary sludge, cholelithiasis), hair loss, headache, hyperglycemia, hypoglycemia, joint pain, nausea, pancreatitis, pollakiuria, pruritus, urinary tract infection, visual disturbances, vomiting, and weakness. In rare cases, GI side effects may resemble intestinal obstruction with progressive abdominal distension, severe epigastric pain, abdominal tenderness, and guarding. Many other side effects occur in fewer than 1% of patients. Side effects that occur more often in patients with acromegaly include cardiac abnormalities (e.g., sinus bradycardia, ECG changes [including QT prolongation], conduction abnormalities, and arrhythmias) and hypothyroidism.

Overdose:

Arrhythmia, brain hypoxia, cardiac arrest, diarrhea, flushing, hepatic steatosis, hepatomegaly, hypotension, lactic acidosis, lethargy, pancreatitis, weakness, and weight loss.

Post-Marketing:

Cholelithiasis, cholecystitis, cholangitis, and pancreatitis (sometimes requiring cholecystectomy), intestinal obstruction, thrombocytopenia.

ANTIDOTE

Keep physician informed of all side effects. If complications of cholelithiasis are suspected, discontinue and treat appropriately. A dose adjustment of either octreotide or other concomitant therapies may be required. Symptomatic and supportive treatment may be indicated. Overdose will cause hyperglycemia or hypoglycemia depending on tumor involved and endocrine status of patient. Discontinue octreotide temporarily, notify the physician, and monitor the patient carefully. Symptomatic treatment should be sufficient.

OFATUMUMAB BBW

(oh-**FAT**-oo-moo-mab)
Arzerra
Monoclonal antibody
Antineoplastic
pH 5.5

USUAL DOSE

Pretreatment:

Baseline studies required; see Monitor.

Premedication:

Patients should receive all of the following premedication agents 30 minutes to 2 hours before each infusion of ofatumumab. The premedication schedule is listed in the following chart.

Premedication Schedule for Ofatumumab					
	Previously Untreated CLL, Relapsed CLL, or Extended Treatment in CLL		**Refractory CLL**		
Infusion number	1 and 2	3 and beyond[a]	1, 2, and 9	3 to 8	10 to 12
IV corticosteroid (prednisolone or equivalent)	50 mg	0 to 50 mg[b]	100 mg	0 to 100 mg[b]	50 to 100 mg[c]
Oral acetaminophen	1,000 mg				
Oral or IV antihistamine	Diphenhydramine 50 mg or cetirizine 10 mg (or equivalent)				

[a] Up to 13 infusions for previously untreated CLL; up to 7 infusions in relapsed CLL; up to 14 infusions for extended treatment in CLL.

[b] Corticosteroid may be reduced or omitted for subsequent infusions if a Grade 3 or greater infusion-related adverse event did not occur with the preceding infusion(s).

[c] Prednisolone may be given at a reduced dose of 50 to 100 mg (or equivalent) if a Grade 3 or greater infusion-related adverse event did not occur with Infusion 9.

Previously untreated chronic lymphocytic leukemia (CLL):

300 mg as the initial dose (Day 1). Follow 1 week later (on Day 8) with 1,000 mg (Cycle 1). Follow with 1,000 mg on Day 1 of subsequent 28-day cycles for a minimum of 3 cycles until best response or a maximum of 12 cycles. Given in combination with chlorambucil.

Relapsed CLL:

300 mg as the initial dose (Day 1). Follow 1 week later (on Day 8) with 1,000 mg (Cycle 1). Follow with 1,000 mg on Day 1 of subsequent 28-day cycles for a maximum of 6 cycles. Given in combination with fludarabine and cyclophosphamide.

Extended treatment in CLL:

300 mg on Day 1. Follow with 1,000 mg 1 week later on Day 8. Follow with 1,000 mg 7 weeks later and every 8 weeks thereafter for up to a maximum of 2 years. Given as a ***single-agent*** extended treatment.

Refractory CLL:

300 mg as the initial dose (Dose 1). Follow 1 week later with 2,000 mg weekly for 7 doses (Doses 2 through 8), followed 4 weeks later with 2,000 mg every 4 weeks for 4 doses (Doses 9 through 12).

DOSE ADJUSTMENTS

Ofatumumab:

Interrupt infusion for an infusion reaction of any severity. Treatment may be resumed at the discretion of the treating physician using the following guidelines. ■ If an infusion reaction resolves with interruption or remains less than or equal to Grade 2, resume infusion with the following modifications based on the initial grade of the infusion reaction: *Grade 1 or 2:* infuse at one-half of the previous infusion rate. *Grade 3 or 4:* infuse at 12 mL/hr. After resuming the infusion, the rate may be increased according to the chart in Rate of Administration. ■ Consider permanent discontinuation if the severity of the infusion reaction does not resolve to equal to or less than Grade 2 despite adequate clinical intervention. Permanently discontinue therapy in patients who develop an anaphylactic reaction. ■ No dose adjustment is indicated for age, body weight, or gender.

DILUTION

Do not shake ofatumumab in vial or solution. Should be a clear to opalescent colorless solution. Prepare all doses in 1,000 mL of NS.

300-mg dose:

Withdraw and discard 15 mL from a 1,000-mL bag of NS. Withdraw 5 mL from each of 3 (100-mg) vials of ofatumumab and add to the bag of NS.

1,000-mg dose:

Withdraw and discard 50 mL from a 1,000-mL bag of NS. Withdraw 50 mL from 1 single-use 1,000-mg vial of ofatumumab and add to the bag of NS.

2,000-mg dose:

Withdraw and discard 100 mL from a 1,000-mL bag of NS. Withdraw 50 mL from each of 2 (1,000-mg) vials of ofatumumab and add to the bag of NS.

Mix all diluted solution by gentle inversion. Administer using an infusion pump and PVC administration sets.

Filters:

An in-line filter is no longer provided or required; see latest prescribing information.

Storage:

Refrigerate vials and prepared solutions between 2° to 8° C (36° to 46° F). Protect vials from light and do not freeze. Start infusion within 12 hours of preparation and discard the prepared solution after 24 hours.

COMPATIBILITY

Manufacturer states, “Do not mix ofatumumab with, or administer as an infusion with, other medicinal products.” Flush the IV line with NS before and after each dose. “No **incompatibilities** observed with polyvinylchloride or polyolefin bags and administration sets.”

RATE OF ADMINISTRATION

For IV infusion only. Use of an infusion pump and PVC administration set is required. Flush the IV line with NS before and after each dose. Interrupt infusion for infusion reactions of any severity; see Dose Adjustments.

Previously untreated CLL, relapsed CLL, and extended treatment in CLL:

300-mg dose:

Initiate infusion at a rate of 3.6 mg/hr (12 mL/hr).

1,000-mg dose:

Initiate infusion at a rate of 25 mg/hr (25 mL/hr). Reduce to 12 mg/hr if a Grade 3 or greater infusion-related reaction (IRR) occurred during the previous infusion.

If there is no IRR, the rate may be increased every 30 minutes as described in the following chart. Do not exceed these infusion rates.

Ofatumumab Infusion Rates for Previously Untreated CLL, Relapsed CLL, and Extended Treatment in CLL		
Interval After Start of Infusion	**Initial 300-mg Dose[a] (mL/hr)**	**Subsequent Infusions[b] (mL/hr)**
0 to 30 minutes	12 mL/hr	25 mL/hr
31 to 60 minutes	25 mL/hr	50 mL/hr
61 to 90 minutes	50 mL/hr	100 mL/hr
91 to 120 minutes	100 mL/hr	200 mL/hr
121 to 150 minutes	200 mL/hr	400 mL/hr
151 to 180 minutes	300 mL/hr	400 mL/hr
>180 minutes	400 mL/hr	400 mL/hr

[a] **Initial 300 mg:** Median duration of infusion = 4.8 to 5.2 hours.

[b] **Subsequent infusions of 1,000 mg:** Median duration of infusion = 4.2 to 4.4 hours.

Refractory CLL:

Dose 1 (300-mg dose):

Initiate infusion at a rate of 3.6 mg/hr (12 mL/hr).

Dose 2 (2,000-mg dose):

Initiate infusion at a rate of 24 mg/hr (12 mL/hr).

Doses 3 through 12 (2,000-mg doses):

Initiate infusion at a rate of 50 mg/hr (25 mL/hr).

If there is no infusion reaction, the rate may be increased every 30 minutes as described in the following chart. Do not exceed these infusion rates.

Ofatumumab Infusion Rates in Refractory CLL		
Interval After Start of Infusion	**Infusions 1 and 2[a] (mL/hr)**	**Subsequent Infusions[b] (mL/hr)**
0 to 30 minutes	12 mL/hr	25 mL/hr
31 to 60 minutes	25 mL/hr	50 mL/hr
61 to 90 minutes	50 mL/hr	100 mL/hr
91 to 120 minutes	100 mL/hr	200 mL/hr
>120 minutes	200 mL/hr	400 mL/hr

[a] **Infusions 1 and 2 (300 mg and 2,000 mg):** Median duration of infusion = 6.8 hours.

[b] **Subsequent infusions (2,000 mg):** Median duration of infusion = 4.2 to 4.4 hours.

ACTIONS

A CD20-directed cytolytic monoclonal antibody (also known as an IgGlk human monoclonal antibody). The CD20 molecule is expressed on normal B lymphocytes and on B-cell CLL. Ofatumumab binds specifically to both the small and large extracellular loops of the CD20 molecule, resulting in B-cell lysis. Possible mechanisms of cell lysis include complement-dependent cytotoxicity and antibody-dependent, cell-mediated cytotoxicity. Decreases circulating CD19-positive B-cells. Ofatumumab is eliminated through both a target-independent route and a B-cell–mediated route. With depletion of B-cells, the clearance of ofatumumab decreases substantially after subsequent infusions compared with the first infusion. The mean half-life after repeated infusions was approximately 17.6 days.

INDICATIONS AND USES

Used in combination with chlorambucil for the treatment of previously untreated patients with CLL when fludarabine-based therapy is considered inappropriate. ■ Used in combination with fludarabine and cyclophosphamide for treatment of patients with relapsed CLL. ■ Extended treatment of patients who are in complete or partial response after at least two lines of therapy for recurrent or progressive CLL. ■ Treatment of patients with chronic lymphocytic leukemia (CLL) refractory to fludarabine and alemtuzumab.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Do not administer as an IV push or bolus or SC injection. For IV infusion only. ■ Administered under the supervision of a physician experienced in the use of antineoplastic therapy in a facility equipped to monitor the patient and respond to any medical emergency. ■ Serious, including fatal, infusion reactions have occurred. Seem to occur more frequently with the first 2 infusions and may occur despite premedication; see Monitor. ■ Severe cytopenias, including anemia, neutropenia, and thrombocytopenia, have occurred with ofatumumab. Pancytopenia, agranulocytosis, and fatal neutropenic sepsis have occurred in patients receiving ofatumumab in combination with chlorambucil. Grade 3 or 4 late-onset neutropenia (onset at least 42 days after the last treatment dose) and/or prolonged neutropenia (not resolved between 24 and 42 days after the last treatment dose) have been reported. ■ Progressive multifocal leukoencephalopathy (PML) resulting in death has been reported. ■ Hepatitis B virus (HBV) reactivation can occur in patients receiving ofatumumab and, in some cases, has resulted in fulminant and fatal hepatitis, hepatic failure, and death. For patients who show evidence of hepatitis B infection, consult physician with expertise in managing hepatitis regarding monitoring and consideration for HBV antiviral therapy. Insufficient data exist regarding the safety of ofatumumab administration in patients who develop HBV reactivation. ■ Fatal infection due to hepatitis B in patients who have not been previously infected has also been observed. ■ Tumor lysis syndrome (TLS) has been reported and has required hospitalization. Patients with a high tumor burden and/or high circulating lymphocyte counts (greater than 25,000/mm^3) are at greater risk for developing TLS. ■ A protein substance, it has the potential for producing immunogenicity. ■ No studies of ofatumumab use in patients with impaired hepatic function or in patients with a CrCl less than 30 mL/min have been conducted; use with caution. ■ See Monitor.

Monitor:

Obtain baseline CBC and platelet counts and monitor at regular intervals during and after conclusion of therapy. Increase the frequency of monitoring in patients who develop Grade 3 or 4 cytopenias. ■ Monitor for S/S of infusion reactions. S/S have included abdominal pain, anaphylactoid/anaphylactic reactions, angioedema, back pain, bronchospasm, cardiac events (e.g., acute coronary syndrome, arrhythmia, bradycardia, myocardial ischemia/infarction), cytokine release syndrome, dyspnea, fever, flushing, hypertension, hypotension, laryngeal edema, pulmonary edema, rash, syncope, and urticaria. ■ Monitor for new onset of or changes in pre-existing neurologic signs or symptoms. Evaluation for PML includes consultation with a neurologist, brain MRI, and lumbar puncture. ■ Screen patients for hepatitis B virus (HBV) before initiating therapy. Monitor patients with evidence of current or prior HBV closely for clinical and laboratory signs of hepatitis or HBV reactivation during treatment and for up to 12 months after the last infusion. Patients without a history of HBV should also be monitored for S/S of hepatitis. ■ Prevention and treatment of hyperuricemia due to tumor lysis syndrome may be accomplished with adequate hydration and, if necessary, with uric acid–lowering drugs (e.g., allopurinol). Consider initiating prophylaxis 12 to 24 hours before infusion of ofatumumab. Monitor renal function and correct any electrolyte abnormalities that may develop. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Use of prophylactic antiemetics may be indicated to reduce nausea and/or vomiting and to increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated.

Patient Education:

Potential for fetal B-cell depletion when given to a pregnant woman. ■ Blood counts will be required at regular intervals. ■ Avoid vaccination with live virus vaccines. ■ Additional monitoring and possible need for treatment may be required with a history of hepatitis B infection. ■ Promptly report symptoms of the following potential side effects: bleeding, easy bruising or petechiae, fatigue, infection (e.g., cough, fever), infusion reactions (e.g., breathing problems, chills, fever, rash that occur within 24 hours of infusion), pallor or worsening weakness, new or worsening abdominal pain or nausea, new or worsening neurologic S/S, worsening fatigue or yellow discoloration of skin or eyes. ■ See Appendix D, p. 1311.

Maternal/Child:

Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ Use caution if breast-feeding. The effects of local gastrointestinal and limited systemic exposure to ofatumumab are unknown. ■ May cause fetal B-cell depletion. Avoid administering live vaccines to neonates and infants exposed to ofatumumab in utero until B-cell recovery occurs. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No clinically meaningful differences in efficacy were seen between elderly and younger patients. ***Previously untreated CLL:*** A higher incidence of Grade 3 or greater neutropenia and pneumonia were reported in elderly patients. ***Refractory CLL:*** Numbers of patients over 65 years of age in studies were not sufficient to determine a response that might differ from younger patients.

DRUG/LAB INTERACTIONS

Formal drug-drug interaction studies have not been conducted. ■ Do not administer **live virus vaccines** to patients who have recently received ofatumumab. ■ The ability to generate an immune response to any vaccine following administration of ofatumumab has not been studied. ■ Coadministration with ofatumumab did not result in clinically relevant effects on the pharmacokinetics of fludarabine, cyclophosphamide, or chlorambucil or its active metabolite, phenylacetic acid mustard.

SIDE EFFECTS

Previously untreated CLL:

Infusion reactions and neutropenia are most common. Severe cytopenias, including anemia, neutropenia, pancytopenia, thrombocytopenia, agranulocytosis, and fatal neutropenic sepsis, are the most serious side effects in combination with chlorambucil. Other side effects reported included arthralgia, asthenia, headache, herpes simplex, leukopenia, lower respiratory tract infection, and upper abdominal pain.

Relapsed CLL:

Febrile neutropenia, infusion reactions, leukopenia, and neutropenia are the most common side effects reported.

Extended treatment in CLL:

Infusion reactions, neutropenia, and upper respiratory infections are the most common side effects reported.

Refractory CLL:

The most common side effects are anemia, bronchitis, cough, diarrhea, dyspnea, fatigue, fever, nausea, neutropenia, pneumonia, rash, and upper respiratory infections. Fever, infections (some fatal) including pneumonia and sepsis, infusion reactions, and neutropenia were the most common serious side effects.

All diagnoses:

Other side effects reported include abdominal pain, arthralgia, asthenia, back pain, chills, edema, headache, hepatitis B infection or reactivation, herpes simplex, herpes zoster, hypertension, hypogammaglobulinemia, hypotension, influenza, insomnia, intestinal obstruction, leukopenia, lower respiratory tract infection, lymphopenia, muscle spasms, nasopharyngitis, peripheral edema, PML, sinusitis, tachycardia, thrombocytopenia, tumor lysis syndrome, and urticaria.

Post-Marketing:

Cardiac arrest, porphyria cutanea tarda, Stevens-Johnson syndrome.

ANTIDOTE

Notify physician of significant side effects. Temporarily discontinue the infusion for an infusion reaction. Institute medical management for severe infusion reactions, including angina or other S/S of myocardial ischemia as indicated. Delay therapy for serious infection or serious hematologic toxicity until the infection or adverse event resolves. Treatment of most reactions will be supportive. Discontinue medication permanently for severe reactions, including Grade 4 infusion reactions or S/S of PML or in patients who develop reactivation of HBV. Infusion reactions may be treated with acetaminophen, antiemetics (e.g., ondansetron), antihistamines (e.g., diphenhydramine), or corticosteroids (e.g., hydrocortisone) as indicated. Discontinue ofatumumab and provide supportive therapy in overdose. Treat hypersensitivity reactions with epinephrine, antihistamines, and corticosteroids as needed. Resuscitate as indicated.

OLARATUMAB

(**OH**-lar-**AT**-ue-mab)
Lartruvo
Antineoplastic
Monoclonal antibody
pH 5.2 to 6.8

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies required; see Monitor.

Premedication:

Administer diphenhydramine 25 to 50 mg IV and dexamethasone 10 to 20 mg IV before administration of olaratumab on Day 1 of Cycle 1.

Olaratumab:

15 mg/kg administered as an IV infusion over 60 minutes on Days 1 and 8 of each 21-day cycle until disease progression or unacceptable toxicity. For the first 8 cycles, olaratumab is administered with doxorubicin. In clinical studies, patients received doxorubicin 75 mg/M^2 as an IV infusion on Day 1 of each 21-day cycle for a maximum of

8 cycles and were permitted to receive dexrazoxane before doxorubicin in Cycles 5 to 8. See doxorubicin monograph for dosing and dose adjustments.

DOSE ADJUSTMENTS

Interrupt infusion for Grade 1 or 2 infusion-related reactions (IRR). After resolution, infusion may be resumed at 50% of the initial infusion rate. ■ Permanently discontinue for Grade 3 or 4 IRR. ■ For neutropenic fever/infection or Grade 4 neutropenia lasting longer than 1 week, discontinue administration of olaratumab until ANC is 1,000/mm^3 or greater and then permanently reduce the dose to 12 mg/kg. ■ Age, gender, race, and mild to moderate renal or hepatic impairment did not have any clinically important effect on the pharmacokinetics of olaratumab. ■ Body weight correlates with clearance and volume of distribution.

DILUTION

Available as a 500-mg/50 mL (10-mg/mL) clear to slightly opalescent, colorless to slightly yellow solution in a single-dose vial. Withdraw the calculated dose based on patient weight and further dilute with NS to a final volume of 250 mL. Gently invert. Do not shake.

Filter:

No information available.

Storage:

Store vials in refrigerator at 2° to 8° C (36° to 46° F). Keep in original carton to protect from light. ***Do not freeze or shake vials or diluted solution***. Diluted solution may be stored for up to 24 hours under refrigeration and for up to an additional 4 hours at RT. Storage times include the duration of infusion. If refrigerated, allow the diluted solution to come to RT before administration. Discard any unused portion left in vial.

COMPATIBILITY

Manufacturer states, “Do not use dextrose-containing solutions. Do not co-infuse with electrolytes or other medications through the same IV line.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 60 minutes. Flush IV line with NS at the end of the infusion. If diluted solution has been refrigerated, bring to RT before administration. Decrease rate of infusion by 50% in patients who experience a Grade 1 or 2 IRR.

ACTIONS

Olaratumab is a recombinant human IgG1 antibody that binds platelet-derived growth factor receptor alpha (PDGFR-α). Signaling through this receptor plays a role in cell growth, chemotaxis, and mesenchymal stem cell differentiation. The receptor has also been detected on some tumor and stromal cells, including sarcomas, where signaling can contribute to cancer cell proliferation, metastasis, and maintenance of the tumor microenvironment. The interaction between olaratumab and PDGFR-α prevents binding of the receptor by the PDGF-AA and PDGF-BB ligands as well as PDGF-AA, PDGF-BB, and PDGF-CC–induced receptor activation and downstream PDGFR-α pathway signaling. Olaratumab exhibits in vitro and in vivo antitumor activity against selected sarcoma cell lines and disrupted the PDGFR-α signaling pathway in in vivo tumor implant models. Half-life is approximately 11 days (range 6 to 24 days).

INDICATIONS AND USES

Treatment of adult patients with soft tissue sarcoma (STS) with a histologic subtype for which an anthracycline-containing regimen is appropriate and that is not amenable to curative treatment with radiotherapy or surgery. Given in combination with doxorubicin. This indication was approved under accelerated approval. Continued approval may be contingent on verification and description of clinical benefit in the confirmatory trial.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For IV infusion only. Do not administer as an IV push or bolus. ■ Should be administered by or under the direction of a physician specialist in a facility equipped to monitor the patient and respond to any medical emergency. ■ Infusion-related reactions (IRRs) have been reported. Most occurred during the first or second cycle. Premedication required; see Usual Dose, Dose Adjustments, and Antidote. ■ May cause fetal harm; see Maternal/Child. ■ The pharmacokinetics of olaratumab in patients with severe renal or hepatic impairment is unknown. ■ A therapeutic protein; has the potential for immunogenicity.

Monitor:

Premedication required; see Usual Dose. ■ Obtain baseline CBC with differential and platelets and monitor as indicated during therapy. ■ Monitor patients during and following olaratumab infusion for S/S of IRR (e.g., anaphylactic shock, bronchospasms, cardiac arrest, chills, fever, flushing, hypotension [may be severe], shortness of breath).

Patient Education:

Effective contraception required for women of reproductive potential during treatment with and for 3 months after the last dose of olaratumab. ■ Promptly report S/S of an infusion reaction (e.g., chills, dizziness, fever, flushing, shortness of breath).

Maternal/Child:

Based on animal data and its mechanism of action, olaratumab can cause fetal harm when administered to a pregnant woman. ■ May impair male fertility. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients have not been established.

Elderly:

Clinical studies did not include sufficient numbers of patients 65 years of age and older to determine whether they respond differently than do younger patients.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ No clinically relevant changes in the exposure of either olaratumab or doxorubicin were observed when coadministered in recommended doses to patients with solid tumors.

SIDE EFFECTS

The most common adverse reactions seen with olaratumab plus doxorubicin are abdominal pain, alopecia, decreased appetite, diarrhea, fatigue, headache, mucositis, musculoskeletal pain, nausea, neuropathy, and vomiting. The most common laboratory abnormalities were elevated aPTT, hyperglycemia, hypokalemia, hypophosphatemia, lymphopenia, neutropenia, and thrombocytopenia. The most common adverse reaction leading to dose reduction was Grade 3 or 4 neutropenia. Anemia, neutropenia, and thrombocytopenia were the adverse reactions most commonly responsible for a dose delay. The most common adverse reaction leading to discontinuation of olaratumab was IRR. Other commonly reported adverse reactions included anxiety, dry eyes, hypomagnesemia, and increased alkaline phosphatase.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Permanently discontinue for Grade 3 or 4 IRR. Treat infusion and hypersensitivity reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids); see Dose Adjustments. Resuscitate as necessary.

OMADACYCLINE

(ooh-mad-a-**SYE**-kleen)
Nuzyra
Antibacterial (tetracycline)

USUAL DOSE

Administer as outlined in the following chart.

Omadacycline Dosing in Adult Patients With Community-Acquired Bacterial Pneumonia (CABP) and Acute Bacterial Skin and Skin Structure Infection (ABSSSI)			
Diagnosis	**Loading Dose**	**Maintenance Dose**	**Treatment Duration**
Community-acquired bacterial pneumonia (CABP)[a]	200 mg IV over 60 minutes on Day 1 Or 100 mg IV over 30 minutes twice on Day 1	100 mg IV over 30 minutes once daily Or 300 mg PO once daily	7 to 14 days
Acute bacterial skin and skin structure infections (ABSSSI)[a]	200 mg IV over 60 minutes on Day 1 Or 100 mg IV over 30 minutes twice on Day 1 Or 450 mg PO once daily on Day 1 and Day 2	100 mg IV over 30 minutes once daily Or 300 mg PO once daily	7 to 14 days

[a] Administer loading dose for patients with CABP as an IV infusion. The loading dose for patients with ABSSSI may be administered orally or as an IV infusion.

The exposure of omadacycline is similar between a 300-mg oral dose and a 100-mg IV dose.

DOSE ADJUSTMENTS

No dose adjustments are required for patients with renal or hepatic impairment. ■ No clinically significant differences in the pharmacokinetics of omadacycline were observed based on age, gender, race, or weight.

DILUTION

Available as a yellow to orange, lyophilized powder in single-dose vials containing 100 mg of omadacycline. Reconstitute the required number of vials needed to make the dose by injecting 5 mL of SWFI, NS, or D5W into each vial. Gently swirl the contents and let the vial stand until the cake has completely dissolved and any foam has dispersed. **Do not shake.** The reconstituted product should be a clear, yellow to dark orange solution. Immediately (within 1 hour) withdraw 5 mL (100-mg dose) or 10 mL (200-mg dose) of the reconstituted solution and further dilute in 100 mL of NS or D5W. The concentration of the final diluted infusion solution will be either 1 mg/mL (100-mg dose) or 2 mg/mL (200-mg dose).

Filter:

Specific information not available.

Storage:

Store unopened vials at CRT. Do not freeze. The reconstituted solution should be diluted within 1 hour of reconstitution. The diluted solution must be infused within 24 hours if stored at RT or within 48 hours if refrigerated at 2° to 8° C (36° to 46° F). Do not freeze.

If stored in the refrigerator, the infusion bag should be removed from the refrigerator and incubated in a vertical position at RT for 60 minutes before use. Discard unused portions of the reconstituted or diluted solution.

COMPATIBILITY

Manufacturer states, "Do NOT administer omadacycline with any solution containing multivalent cations (e.g., calcium and magnesium) through the same intravenous line. The compatibility of omadacycline with other drugs and infusion solutions other than D5W or NS has not been established."

RATE OF ADMINISTRATION

Administer through a dedicated line or through a Y-site. If the same IV line is used for sequential infusion of several drugs, the line should be flushed with NS or D5W before and after the infusion of omadacycline.

Loading dose:

Administer 200 mg as an IV infusion over 60 minutes.

Maintenance dose:

Administer 100 mg as an IV infusion over 30 minutes.

ACTIONS

A semisynthetic aminomethylcycline antibacterial within the tetracycline class of antibacterial drugs. Omadacycline binds to the 30s ribosomal subunit and blocks protein synthesis. In general, omadacycline is considered bacteriostatic; however in vitro bactericidal activity has been demonstrated against certain strains of *Streptococcus pneumoniae* and *Haemophilus influenzae*. Active against selected gram-positive and gram-negative bacteria; see prescribing information and Indications. Omadacycline distributes into the lungs. Steady-state exposures in alveolar cells and epithelial lining fluid are higher than plasma exposures. Plasma protein binding is approximately 20% and is not concentration dependent. Omadacycline does not appear to be metabolized. Half-life is 16 hours. Excreted in feces and urine.

INDICATIONS AND USES

Treatment of adult patients with community-acquired bacterial pneumonia (CABP) caused by the following susceptible microorganisms: *S. pneumoniae*, *Staphylococcus aureus* (methicillin-susceptible isolates), *H. influenzae, Haemophilus parainfluenzae, Klebsiella pneumoniae, Legionella pneumophila, Mycoplasma pneumoniae,* and *Chlamydophila pneumoniae.* ■ Treatment of adult patients with acute bacterial skin and skin structure infections (ABSSSI) caused by the following susceptible microorganisms: *S. aureus* (methicillin-susceptible and methicillin-resistant isolates), *Staphylococcus lugdunensis, Streptococcus pyogenes, Streptococcus anginosus* group (includes *S. anginosus, S. intermedius,* and *S. constellatus*), *Enterococcus faecalis, Enterobacter cloacae,* and *K. pneumoniae.*

CONTRAINDICATIONS

Known hypersensitivity to omadacycline, tetracycline-class antibacterial drugs, or to any of the excipients. Not recommended in pediatric patients under 8 years of age or in breast-feeding.

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, omadacycline should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to omadacycline. ■ Mortality imbalance was observed in the CABP clinical trial, with eight deaths (2%) occurring in patients treated with omadacycline compared with four deaths (1%) in patients treated with moxifloxacin. The cause of the mortality imbalance has not been established. All deaths in both treatment arms occurred in patients greater than 65 years of age; most patients had multiple comorbidities. The causes of death varied and included worsening and/or complications of infection and underlying conditions. ■ Exposure during the last half of pregnancy, infancy, and childhood to 8 years of age may cause permanent discoloration of the teeth. This adverse reaction is more common during long-term use of the tetracycline-class drugs but has also been observed after repeated short-term courses. Enamel hypoplasia has also been reported with the tetracycline-class drugs. ■ The use of omadacycline during the second and third trimester of pregnancy, infancy, and childhood up to 8 years of age may cause reversible inhibition of bone growth. All tetracyclines form a stable calcium complex in any bone-forming tissue. ■ Life-threatening hypersensitivity (anaphylactic) reactions have been reported with other tetracycline-class antibacterial drugs. Omadacycline is structurally similar to other tetracycline-class antibacterial drugs and should not be administered to patients with known hypersensitivity to any drug in this class; see Contraindications. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild to life threatening. Consider in patients who present with diarrhea during or after treatment with omadacycline. ■ Omadacycline is structurally similar to tetracycline-class antibacterial drugs and may have similar adverse reactions. Adverse reactions, including photosensitivity, pseudotumor cerebri, and anti-anabolic action leading to increased BUN, azotemia, acidosis, hyperphosphatemia, pancreatitis, and abnormal liver function tests, have been reported for other tetracycline-class antibacterial drugs and may occur with omadacycline. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ May be active against some organisms that are normally resistant to other tetracyclines.

Monitor:

Closely monitor clinical response to therapy in CABP patients, particularly in those at higher risk for mortality. ■ Monitor for S/S of hypersensitivity reactions. ■ Determine absolute patency of vein and avoid extravasation; thrombophlebitis may occur. ■ Monitor hematopoietic, renal, and hepatic studies periodically in long-term therapy.

Patient Education:

May cause embryonic or fetal harm. Use of effective contraception advised. ■ Promptly report severe diarrhea, S/S of hypersensitivity reactions, or any other side effect. ■ May cause permanent tooth discoloration of deciduous teeth and reversible inhibition of bone growth when administered during the second and third trimesters of pregnancy. Tell your health care provider right away if you become pregnant during treatment. ■ Alert patient to the possibility of a photosensitive skin reaction.

Maternal/Child:

Data on use in pregnant women are limited. May cause permanent tooth discoloration of deciduous teeth and reversible inhibition of bone growth when administered during the second and third trimesters of pregnancy. Consider risk versus benefit. ■ Discontinue breast-feeding during treatment and for 4 days after the last dose. ■ Safety and effectiveness of omadacycline in pediatric patients have not been established. Due to the adverse effects on tooth development and bone growth, use in pediatric patients under 8 years of age is not recommended.

Elderly:

In clinical trials, numerically lower clinical success rates at an early clinical response time point were observed in CABP patients 65 years of age or older compared with patients under 65 years of age. In addition, all deaths that occurred in the CABP trial occurred in patients 65 years of age or older. ■ No clinically relevant differences in the pharmacokinetics of omadacycline were observed with respect to age in a population pharmacokinetic analysis of omadacycline.

DRUG/LAB INTERACTIONS

Because tetracyclines have been shown to depress plasma prothrombin activity, patients who are on **anticoagulant therapy** may require downward adjustment of their anticoagulant dosage.

SIDE EFFECTS

The most common adverse reactions are constipation; diarrhea; headache; hypertension; increased ALT, AST, and gamma-glutamyl transferase; infusion site reactions; insomnia; nausea; and vomiting. Several other adverse reactions were reported in fewer than 2% of patients. An imbalance in mortality, *C. difficile*–associated diarrhea, inhibition of bone growth, and tooth discoloration have been reported. The possibility of tetracycline-class adverse reactions exists; see Precautions.

ANTIDOTE

Notify the physician of all side effects. Discontinue omadacycline at the first sign of a hypersensitivity reaction or if the development of any tetracycline class adverse drug reaction is suspected. Treat hypersensitivity reactions as indicated (e.g., antihistamines, epinephrine, corticosteroids) and resuscitate as necessary. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin), as indicated. In severe cases, surgical evaluation may be indicated. Significant quantities are not expected to be removed by hemodialysis.

ONASEMNOGENE ABEPARVOVEC-xioi BBW

(**ON**-a-**SEM**-noe-jeen **A**-be-**PAR**-voe-vek)
Zolgensma
Adeno-associated virus vector-based gene therapy

PEDIATRIC DOSE

Pretreatment:

Baseline studies and pretesting required; see Monitor. When possible, adjust a patient's vaccination schedule to accommodate concomitant corticosteroid administration before and after onasemnogene abeparvovec infusion. Certain vaccines, such as MMR and varicella, are contraindicated for patients on a substantially immunosuppressive steroid dose (i.e., 2 weeks or more of daily receipt of 20 mg or 2 mg/kg of prednisone or equivalent). Seasonal RSV prophylaxis is not precluded.

Premedication:

Administer systemic corticosteroid to all patients before and after onasemnogene infusion. One day before the infusion, begin administration of systemic corticosteroids equivalent to oral prednisolone at 1 mg/kg/day and continue each day for a total of 30 days.

Onasemnogene abeparvovec-xioi:

1.1×10^{14} vector genomes per kilogram (vg/kg) of body weight. **For single-dose IV infusion only;** administer through a venous catheter.

Onasemnogene Abeparvovec-xioi Dosing Volume Based on Patient Weight Range (kg)	
Patient Weight Range (kg)	**Dose Volume[a] (mL)**
2.6 to 3 kg	16.5 mL
3.1 to 3.5 kg	19.3 mL
3.6 to 4 kg	22 mL
4.1 to 4.5 kg	24.8 mL
4.6 to 5 kg	27.5 mL
5.1 to 5.5 kg	30.3 mL
5.6 to 6 kg	33 mL
6.1 to 6.5 kg	35.8 mL
6.6 to 7 kg	38.5 mL
7.1 to 7.5 kg	41.3 mL
7.6 to 8 kg	44 mL
8.1 to 8.5 kg	46.8 mL
8.6 to 9 kg	49.5 mL
9.1 to 9.5 kg	52.3 mL
9.6 to 10 kg	55 mL
10.1 to 10.5 kg	57.8 mL
10.6 to 11 kg	60.5 mL
11.1 to 11.5 kg	63.3 mL
11.6 to 12 kg	66 mL
12.1 to 12.5 kg	68.8 mL
12.6 to 13 kg	71.5 mL
13.1 to 13.5 kg[b]	74.3 mL

[a] Dose volume is calculated using the upper limit of the patient weight range for pediatric patients under 2 years weighing between 2.6 and 13.5 kg.

[b] Dose volume for pediatric patients under 2 years weighing 13.6 kg or more will require a combination of onasemnogene kits.

DILUTION

Available as a suspension for IV infusion in a kit containing 2 to 9 vials. Vials are provided in 2 fill volumes: 5.5 mL or 8.3 mL. Thaw before use. Kit contents will thaw in approximately 12 hours in a refrigerator or in approximately 4 hours if placed at RT. If thawed in a refrigerator, remove from refrigerator on the day of dosing. At RT it should be a clear to slightly opaque, colorless to faint white liquid, and free of particles. Do not use if particulates or discoloration are present. ***Do not shake.*** Draw the appropriate dose volume from all vials into a syringe, remove air from the syringe, cap, and deliver at RT to the patient infusion location. Place a primary catheter into a vein (generally a peripheral vein in the arm or leg). Insertion of a back-up catheter is recommended.

Program a syringe pump for saline priming or prime tubing manually with saline. See Rate of Administration.

Filters:

Specific information not available.

Storage:

Stored and shipped frozen (−60° C [−76° F]). Upon receipt, immediately place the kit in the refrigerator at 2° to 8° C (36° to 46° F). Stable for 14 days from receipt when stored at 2° to 8° C (36° to 46° F). ***Do not refreeze***. Use within 8 hours of drawing into syringe. Discard if the drug is not infused within the 8-hour time frame.

COMPATIBILITY

Information not provided by manufacturer. For single use only. Administered via a dedicated venous catheter.

RATE OF ADMINISTRATION

Place a primary catheter into a vein (generally a peripheral vein in the arm or leg). Insertion of a back-up catheter is recommended. Program a syringe pump for saline priming, or prime tubing manually with saline.

Onasemnogene :

Using a programmed syringe pump, administer as a ***slow infusion over 60 minutes. Do Not infuse as an IV push or bolus***. Flush the line with saline following completion of infusion.

ACTIONS

Onasemnogene abeparvovec-xioi is a recombinant AAV9-based gene therapy designed to deliver a copy of the gene encoding the human survival motor neuron (SMN) protein. Spinal muscular atrophy (SMA) is caused by a biallelic mutation in the SMN1 gene, which results in insufficient SMN protein expression. IV administration of onasemnogene abeparvovec-xioi that results in cell transduction and expression of the SMN protein has been observed in two human case studies. Following administration, generalized SMN expression was visualized in spinal motor neurons, in neuronal and glial cells of the brain, and in the heart, liver, skeletal muscles, and other tissues. Vector DNA is shed in saliva, urine, and stool after infusion, with much higher concentrations found in stool than in saliva or urine. The vector DNA concentration declined to undetectable levels within 1 to 2 weeks in urine, within 3 weeks in saliva, and within 1 to 2 months in stool.

INDICATIONS AND USES

Treatment of pediatric patients under 2 years of age with spinal muscular atrophy (SMA) with biallelic mutations in the *survival motor neuron 1 (SMN1) gene.*

Limitation of use:

Safety and effectiveness of repeat administration have not been evaluated. ■ Use in patients with advanced SMA (e.g., complete paralysis of limbs, permanent ventilator dependence) has not been evaluated.

CONTRAINDICATIONS

Manufacture states, “None.”

PRECAUTIONS

Acute serious liver injury and elevated aminotransferases can occur. Patients with pre-existing liver impairment may be at higher risk. ■ Transient decreases in platelet counts, some of which met the criteria for thrombocytopenia, have been observed at different time points after the infusion. ■ Transient increases in cardiac troponin I levels (up to 0.176 mcg/L) were also observed. Clinical importance is not known, but cardiac toxicity was observed in animal studies. ■ Safety and efficacy of use in patients with anti-AAV9 antibody titers above 1:50 have not been evaluated. ■ See Maternal/Child.

Monitor:

Before the infusion of onasemnogene, assess liver function by clinical examination and obtain baseline liver function tests (AST, ALT, total bilirubin, and prothrombin time). ■ Obtain baseline platelet counts and troponin I levels. ■ Perform baseline testing for the presence of anti-AAV9 antibodies before the onasemnogene infusion. Retesting may be performed if anti-AAV9 antibody titers are reported as more than 1:50. ■ Monitor liver function for at least 3 months after infusion, repeating liver function tests weekly for the first month and every other week for the second and third months, until results are unremarkable (normal clinical exam, total bilirubin, and prothrombin time; and ALT and AST levels below 2 times the ULN). ■ Repeat platelet counts weekly for the first month and then every other week for the second and third months until platelet counts return to baseline. ■ Repeat troponin I testing weekly for the first month, and then monthly for the second and third months, until troponin I level returns to baseline. ■ At the end of the 30-day period of systemic corticosteroid treatment, check liver status clinically and by assessing ALT, AST, total bilirubin, and prothrombin time. If findings are unremarkable (normal clinical exam, total bilirubin, and prothrombin time; and ALT and AST levels are below 2 times the ULN), taper the corticosteroid dose over the next 28 days. If liver function abnormalities persist, continue systemic corticosteroids (equivalent to oral prednisolone at 1 mg/kg/day) until ALT and AST values are both below 2 times the ULN and all other assessments return to normal range, and then taper the corticosteroid dose over the next 28 days. ■ Consult expert(s) if patients do not respond adequately to the equivalent of 1 mg/kg/day oral prednisolone.

Patient Education:

Inform caregivers that liver enzyme levels may increase and that onasemnogene abeparvovec can cause acute serious liver injury. Patients will receive oral corticosteroid medication before and after the infusion and will have regular blood tests to monitor liver function. ■ Immediately report a yellowish color of the skin or whites of the eyes or if the patient misses a dose of corticosteroid or vomits it up. ■ Consult your health care provider to adjust the vaccination schedule appropriately to accommodate treatment with corticosteroids. ■ Prophylaxis against respiratory syncytial virus is recommended. ■ A viral respiratory infection could lead to more serious complications. Promptly report coughing, fever, runny nose, sneezing, sore throat, or wheezing. ■ Promptly report unexpected bruising or bleeding. ■ Special handling of body waste (feces) is required because of vector shedding of onasemnogene. Use proper handwashing techniques whenever in contact with patient body waste, and seal disposable diapers in disposable trash bags before discarding into regular trash. Special handling precautions should be followed for 1 month after the infusion.

Maternal/Child:

Not intended for use in pregnancy or in women who are breast-feeding. ■ There is no information on whether breast-feeding should be restricted in mothers who may be seropositive for anti-AAV9 antibodies. ■ Administration of onasemnogene to premature neonates before reaching full-term gestational age is not recommended because concomitant treatment with corticosteroids may adversely affect neurologic development. Delay administration until the corresponding full-term gestational age is reached.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Elevated aminotransferases (ALT, AST) and vomiting are the most common side effects. Acute serious liver injury, thrombocytopenia, and elevated troponin I are serious reactions.

ANTIDOTE

Notify physician of all side effects. Strict adherence to clinical evaluation of liver function and liver function testing, testing of platelet counts, and troponin I levels is imperative; see Monitor. Strictly observe corticosteroid dosing; see Monitor and Premedication. If a hypersensitivity reactions should occur, treat as appropriate (e.g., oxygen, antihistamines, epinephrine, corticosteroids, vasopressors, and/or fluids).

ONDANSETRON HYDROCHLORIDE

(on-**DAN**-sih-tron hy-droh-**KLOR**-eyed)
Ondansetron HCl PF, Zofran, Zofran PF
Antiemetic $5HT_3$ receptor antagonist
pH 3 to 4

USUAL DOSE

Prevention of nausea and vomiting associated with emetogenic cancer chemotherapy in adult and pediatric patients 6 months of age and older:

Three 0.15 mg/kg of body weight doses up to a maximum of 16 mg/dose. Administer the first dose 30 minutes before giving emetogenic cancer chemotherapy (e.g., cisplatin, methotrexate). Given as an intermittent infusion over 15 minutes. Repeat 0.15 mg/kg dose up to a maximum of 16 mg/dose at 4 and 8 hours after the first dose. Concurrent use with dexamethasone may improve the effectiveness of ondansetron in controlling cisplatin-induced nausea and vomiting.

Prevention of postoperative nausea and/or vomiting in adults and pediatric patients 1 month to 12 years of age weighing more than 40 kg:

4 mg *undiluted* before anesthesia induction or postoperatively if the patient did not receive prophylactic antiemetics and experiences nausea or vomiting within 2 hours after surgery. Although repeat doses are not recommended by the manufacturer, they have been given. Benefit of repeat dosing has not been demonstrated in studies.

PEDIATRIC DOSE

See Maternal/Child.

Nausea associated with emetogenic cancer chemotherapy agents in pediatric patients 6 months of age and older:

See Usual Dose.

Postoperative nausea in pediatric patients 1 month to 12 years of age:

Given immediately before or following anesthesia induction or postoperatively if the patient did not receive prophylactic antiemetics and experiences nausea or vomiting shortly after surgery. See comments under Usual Dose.

Weight 40 kg or less:

0.1 mg/kg.

Weight more than 40 kg:

See Usual Dose.

DOSE ADJUSTMENTS

No dose adjustment required for the elderly or in renal disease. ■ Before emetogenic chemotherapy, a single maximum daily dose of 8 mg is suggested for patients with severe hepatic disease (Child-Pugh score of 10 or greater).

DILUTION

Available in a 20-mL multidose vial (2 mg/mL) and in premixed solutions.

IV injection:

Dilution is not required in adult and pediatric patients when given as an IV injection for the prevention of postoperative nausea and vomiting.

Intermittent infusion:

Dilution of each single dose in 50 mL of NS or D5W is required in adult and pediatric patients when ondansetron is given for the prevention of nausea and vomiting associated with emetogenic chemotherapy. In pediatric patients 6 months to 1 year of age and/or 10 kg or less, dilute in 10 to 50 mL of D5W or NS depending on patient's fluid needs. See Compatibility for additional diluents.

Storage:

Store unopened vials between 2° and 30° C (36° and 86° F). Protect from light. Stable at RT under normal lighting conditions for 48 hours after dilution. However, manufacturer recommends that the dilution not be used beyond 24 hours. Shake vigorously to resolubilize if a precipitate forms at the stopper/vial interface.

COMPATIBILITY

Manufacturer states, "Do not mix with alkaline solutions as a precipitate may form" and lists as **compatible** and stable for up to 48 hours with D5W, NS, D5/½NS, D5NS, or 3% NaCl injection; see Dilution.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection (postoperative nausea and vomiting in adults and pediatric patients 12 years of age and older):

A single 4-mg dose over at least 30 seconds; 2 to 5 minutes preferred.

IV injection (postoperative nausea and vomiting in pediatric patients 1 month to 12 years of age and weighing more than 40 kg):

A single 4-mg dose over at least 30 seconds; 2 to 5 minutes preferred.

IV injection (postoperative nausea and vomiting in pediatric patients 1 month to 12 years of age and weighing 40 kg or less):

A single 0.1-mg/kg dose over at least 30 seconds; 2 to 5 minutes preferred.

Intermittent infusion adults and pediatric patients:

A single dose equally distributed over 15 minutes.

ACTIONS

A selective antagonist of serotonin (5-HT_3) receptors. 5-HT_3 receptors are found both peripherally on vagal nerve terminals and centrally in the chemoreceptor trigger zone. It is unclear whether antiemetic action in chemotherapy-induced nausea and vomiting is mediated centrally, peripherally, or at both sites. Chemotherapeutic agents such as cisplatin increase the release of serotonin from specific cells in the GI tract, causing emesis. By antagonizing these receptors, chemotherapy-induced nausea and vomiting are prevented. Lacks the activity at dopamine receptors of metoclopramide, so it does not cause the same level of sedation. No correlation between plasma levels and antiemetic activity. Metabolized by specific hepatic enzymes of the cytochrome P_{450} isoenzyme system; onset of action is prompt. Half-life is 3.5 to 5.5 hours. Excreted in feces and urine.

INDICATIONS AND USES

Prevention of nausea and vomiting associated with initial and repeat courses of emetogenic cancer chemotherapy, including high-dose cisplatin in patients 6 months of age and older. ■ Prevention of postoperative nausea and/or vomiting in patients 1 month of age and older. ■ Used orally (available as liquid, tablets, and orally disintegrating tablets) for prevention of nausea and vomiting, including postoperative nausea and vomiting, and nausea and vomiting associated with chemotherapy and radiotherapy (including total body irradiation). Approved for IM injection as an alternative to IV in the prevention of postoperative nausea and vomiting.

CONTRAINDICATIONS

Hypersensitivity to ondansetron or any of its components. ■ Concomitant use of apomorphine.

PRECAUTIONS

Sterile technique imperative in withdrawing a single dose from the multidose vial. Available in single-dose and multidose vials and in 4- and 8-mg tablets. ■ Hypersensitivity reactions, including anaphylaxis and bronchospasm, have been reported. Cross-sensitivity has been reported between ondansetron and other $5HT_3$ receptor agonists (e.g., dolasetron or granisetron). ■ Use with caution in patients with hepatic impairment. Clearance is decreased; see Dose Adjustments. ■ Not indicated instead of gastric suction. Use in abdominal surgery or in patients with chemotherapy-induced nausea and vomiting may mask a progressive ileus or gastric distension. ■ May cause ECG changes, including QT-interval prolongation (prolongs the QT interval in a dose-dependent manner). Post-marketing cases of torsades de pointes have been reported. Avoid use in patients with congenital long QT syndrome. Use with caution in patients with electrolyte abnormalities (e.g., hypokalemia, hypomagnesemia), CHF, or bradyarrhythmias or in patients taking other medicines that may lead to QT prolongation; see Monitor and Drug/Lab Interactions. ■ Serotonin syndrome has been reported with $5\text{-}HT_3$ receptor antagonists. Most reports were associated with concomitant use of serotonergic drugs (e.g., selective serotonin reuptake inhibitors [e.g., paroxetine, escitalopram], serotonin and norepinephrine reuptake inhibitors [e.g., duloxetine, venlafaxine], monoamine oxidase inhibitors, mirtazapine, fentanyl, lithium, tramadol). Some cases were fatal. ■ Routine prophylaxis is not recommended for patients in whom there is little expectation of postoperative nausea and vomiting. However, for patients in whom nausea and vomiting must be avoided during the postoperative period, prophylaxis is recommended even when the incidence of postoperative nausea and vomiting is low.

Monitor:

Observe closely. Ambulate slowly to avoid orthostatic hypotension. ■ ECG monitoring is recommended in patients with electrolyte abnormalities (e.g., hypokalemia, hypomagnesemia), CHF, or bradyarrhythmias or in patients taking other medicines that may lead to QT prolongation. ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Monitor for serotonin syndrome, especially when ondansetron is used concurrently with other serotonergic drugs. Symptoms associated with serotonin syndrome may include the following combination of S/S: mental status changes (e.g., agitation, coma, delirium, hallucinations), autonomic instability (e.g., diaphoresis, dizziness, flushing, hyperthermia, labile blood pressure, tachycardia), neuromuscular symptoms (e.g., hyperreflexia, incoordination, myoclonus, rigidity, tremor), and seizures, with or without GI symptoms (e.g., diarrhea, nausea, vomiting). ■ Stool softeners or laxatives may be required to prevent constipation. ■ Monitor for S/S of bowel obstruction in patients after abdominal surgery and in patients with chemotherapy-induced nausea and vomiting.

Patient Education:

May cause dizziness or fainting; request assistance to ambulate. ■ Promptly report difficulty breathing, tightness in the chest, or wheezing. ■ May cause cardiac arrhythmias; discuss personal and family history and all prescription and non-prescription medications with a health care professional. ■ Promptly report any S/S consistent with a potential bowel obstruction. ■ Promptly report S/S of serotonin syndrome (e.g., altered mental status, autonomic instability, and neuromuscular symptoms); see Precautions.

Maternal/Child:

No evidence of impaired fertility or harm to fetus. Use in pregnancy only if potential benefit justifies potential risk. ■ Use caution if required during breast-feeding. ■ Information limited in pediatric cancer patients under 6 months of age and in pediatric surgical patients under 1 month of age. ■ In general, surgical and cancer pediatric patients younger than 18 years tend to have a higher clearance compared with adults, leading to a shorter half-life (2.9 hours). Infants 1 to 4 months of age have a lower clearance, resulting in a longer half-life (6.7 hours). Close monitoring of patients younger than 4 months of age is recommended.

Elderly:

A reduction in clearance and an increase in elimination half-life are seen in patients over 75 years of age. See Dose Adjustments.

DRUG/LAB INTERACTIONS

Does not appear to induce or inhibit the **cytochrome P_{450} isoenzyme system**. ■ **Phenytoin, carbamazepine**, and **rifampin** increase clearance and decrease levels of ondansetron. Dose adjustment not recommended. ■ Concomitant use of **apomorphine** may result in profound hypotension and loss of consciousness; see Contraindications. ■ Concomitant use with **tramadol** may result in reduced analgesic activity of tramadol. See Precautions and use extreme caution with **diuretics or**

antiarrhythmic drugs or other drugs that lead to prolonged QT intervals (e.g., amiodarone, procainamide, quinidine). ■ Serotonin syndrome (including altered mental status, autonomic instability, and neuromuscular symptoms) has been reported following the concomitant use of 5-HT_3 receptor antagonists and other serotonergic drugs, including selective serotonin reuptake inhibitors (SSRIs) and serotonin and norepinephrine reuptake inhibitors (SNRIs); see Precautions.

SIDE EFFECTS

The most common side effects reported were diarrhea, fever, and headache.

Adults:

Agitation, arrhythmias (including ventricular and superventricular tachycardia, PVCs, atrial fibrillation, and bradycardia), chest pain, cold sensation, constipation, cramps, diarrhea, dizziness, drowsiness, ECG alterations (including second-degree heart block, QT-interval prolongation, and ST segment depression), faintness, fatigue, fever, flushing, headache, hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, cardiopulmonary arrest, hypotension, laryngospasm, shock, shortness of breath, stridor, urticaria), hiccups, hypokalemia, injection site reactions, oculogyric crisis, pain (abdominal, joint, musculoskeletal, rib cage, shoulder), palpitations, paresthesia, pruritus, shivering, transient blurred vision or blindness, transient elevation of AST or ALT, urinary retention. Other side effects have occurred (e.g., extrapyramidal reaction, rash) in fewer than 1% of patients. Overdose caused sudden blindness in one patient.

Infants 1 to 24 months:

Bronchospasm, diarrhea, fever, postprocedural pain.

Pediatric patients 2 to 12 years of age:

Anxiety/agitation, drowsiness/sedation, fever, headache, wound problems.

Post-Marketing:

Arthralgia; dyspnea; ECG changes, including QT/QTc interval prolongation; erythema; hepatitis, hepatic necrosis, hepatic failure, and death (in patients receiving potentially hepatotoxic cytotoxic chemotherapy and antibiotics; etiology unclear); hyperhidrosis; increased alkaline phosphatase (ALP), gamma-glutamyl transferase (GGT), and bilirubin; jaundice; laryngeal edema; lethargy; Stevens-Johnson syndrome; torsades de pointes; toxic epidermal necrolysis; ventricular fibrillation. Serotonin syndrome has been reported as a 5-HT_3 class reaction.

ANTIDOTE

Most side effects will be treated symptomatically. Keep physician informed as indicated. Overdose of 10 times the usual dose has not caused significant problems. If symptoms of serotonin syndrome occur, discontinue ondansetron and initiate supportive care. Treat anaphylaxis and resuscitate as necessary.

ORITAVANCIN

(**OR**-it-**A**-van-**SIN**)
Orbactiv
Antibacterial
(lipoglycopeptide)
pH 3.1 to 4.3

USUAL DOSE

A single 1,200-mg dose administered as an infusion over 3 hours.

DOSE ADJUSTMENTS

No dose adjustment is recommended in patients with mild or moderate renal or hepatic impairment. ■ No dose adjustment recommended based on age, gender, weight, or race.

DILUTION

Available in single-use vials containing 400 mg of oritavancin as a lyophilized powder. Three vials are required to prepare a single dose. Reconstitute each 400-mg vial with 40 mL of SWFI. Gently swirl to avoid foaming, and ensure that all oritavancin powder is completely dissolved. Concentration is 10 mg/mL in each vial. Solution should be clear and colorless to pale yellow. Withdraw and discard 120 mL from a 1,000-mL IV bag of D5W. Withdraw 40 mL from each of the three reconstituted vials and add to the D5W IV bag to bring the volume back to 1,000 mL. Final concentration is 1.2 mg/mL.

Filters:

Specific information not available.

Storage:

Vials may be stored at CRT. Reconstituted vials and/or fully diluted solutions may be stored at RT for up to 6 hours or refrigerated at 2° to 8° C (36° to 46° F) for up to 12 hours. Total time from reconstitution to dilution to completion of administration should not exceed 6 hours at RT or 12 hours if refrigerated.

COMPATIBILITY

Manufacturer states, "Use only D5W for dilution. Do **NOT** use NS. NS is **incompatible** with oritavancin and may cause precipitation of the drug. Other IV substances, additives, or other medications mixed in NS should not be added to oritavancin single-use vials or infused simultaneously through the same IV line or through a common IV port. In addition, drugs formulated at a basic or neutral pH may be **incompatible** with oritavancin. If the same IV line is used for sequential infusion of additional medications, the line should be flushed before and after infusion of oritavancin with D5W."

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 3 hours. If a common IV line is used to administer other drugs in addition to oritavancin, flush the IV line before and after each oritavancin infusion with D5W. If an infusion reaction occurs, temporarily stop or slow the infusion as indicated.

ACTIONS

Oritavancin is a semi-synthetic lipoglycopeptide antibacterial drug. It exerts a concentration-dependent bactericidal activity in vitro against *Staphylococcus aureus, Streptococcus pyogenes,* and *Enterococcus faecalis*. It has three mechanisms of action (1) inhibition of the transglycosylation (polymerization) step of cell wall biosynthesis by binding to the stem peptide of peptidoglycan precursors, (2) inhibition of the transpeptidation (cross-linking) step of cell wall biosynthesis by binding to the peptide bridging segments of the cell wall, and (3) disruption of bacterial membrane integrity, leading to depolarization, permeabilization, and cell death. Approximately 85% bound to plasma proteins. Extensively distributed into tissue. Not metabolized. Terminal half-life is approximately 245 hours. Minimally excreted as unchanged drug in feces and urine.

INDICATIONS AND USES

Treatment of adult patients with acute bacterial skin and skin structure infections (ABSSSI) caused by susceptible isolates of designated Gram-positive microorganisms, including *Staphylococcus aureus* (both methicillin-susceptible [MSSA] and methicillin-resistant [MRSA] strains).

CONTRAINDICATIONS

Known hypersensitivity to oritavancin. ■ Use of IV unfractionated heparin sodium is contraindicated for 120 hours (5 days) after oritavancin administration because aPTT test results are expected to remain falsely elevated for up to 120 hours (5 days).

PRECAUTIONS

Oritavancin artificially prolongs the PT and INR for up to 12 hours, making the monitoring of the anticoagulation effect of warfarin unreliable up to 12 hours after an oritavancin dose. Patients receiving both warfarin and oritavancin should be monitored for S/S of bleeding; see Drug/Lab Interactions. ■ The aPTT has been shown to be artificially prolonged for up to 120 hours, the PT and INR for up to 12 hours, and the activated clotting time (ACT) for up to 24 hours after administration of oritavancin. D-dimer concentrations have been shown to be elevated for up to 72 hours after administration; see Drug/Lab Interactions. ■ Serious hypersensitivity reactions have been reported. Check history of previous hypersensitivity reactions to glycopeptides (e.g., dalbavancin, telavancin, vancomycin). Exercise caution in patients with a history of glycopeptide allergy; cross-sensitivity is possible. ■ Infusion-related reactions have been reported; see Rate of Administration. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, oritavancin should be used to treat only those infections proven or strongly suspected to be caused by bacteria. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to oritavancin. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported for nearly all systemic antibacterial agents and may range in severity from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea after treatment with oritavancin. ■ In clinical trials, more cases of osteomyelitis were reported in the oritavancin-treated arm than in the vancomycin-treated arm. If osteomyelitis is suspected or diagnosed, institute appropriate alternate antibacterial therapy. ■ The pharmacokinetics of oritavancin has not been studied in patients with severe renal or hepatic impairment.

Monitor:

Frequently monitor patients on chronic warfarin therapy for signs of bleeding. ■ Monitoring of the anticoagulation effect of warfarin (e.g., PT, INR) is unreliable for up to 12 hours after oritavancin administration; see Precautions and Drug/Lab Interactions. ■ If aPTT monitoring is required within 120 hours of oritavancin dosing, use a non–phospholipid-dependent coagulation test such as a factor Xa (chromogenic) assay, or consider an alternative anticoagulant not requiring aPTT monitoring. ■ Monitor for S/S of hypersensitivity (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing). In clinical trials, the median onset of hypersensitivity reactions was 1.2 days and the median duration of these reactions was 2.4 days. ■ Monitor for S/S of an infusion reaction. Reactions may include flushing of the upper body, pruritus, rash, and/or urticaria (“redman syndrome”); see Rate of Administration. ■ Monitor for S/S of osteomyelitis; see Antidote.

Patient Education:

Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath, wheezing) or an infusion reaction (e.g., flushing of the upper body, pruritus, rash, and/or urticaria). ■ Promptly report diarrhea or bloody stools that occur up to several months after antibiotic therapy; may indicate CDAD and require treatment.

Maternal/Child:

Category C: use during pregnancy only if the potential benefit outweighs the potential risk to the fetus. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Numbers in clinical studies insufficient to determine if the elderly respond differently from younger subjects. Differences have not been identified. However, greater sensitivity of some older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

Clinical drug-drug interaction studies have not been conducted. ■ A screening drug-drug interaction study indicated that oritavancin is a nonspecific weak inducer of CYP3A4 and CYP2D6 and a weak inhibitor of CYP2C9 and CYP2C19. Caution should be used when administering oritavancin with drugs that have a narrow therapeutic window and are predominantly metabolized by one of the affected CYP_{450} enzymes (e.g., **warfarin**). Coadministration may increase or decrease concentrations of drugs with a narrow therapeutic range. ■ Oritavancin has been shown to artificially prolong aPTT for up to 120 hours, PT and INR for up to 12 hours, and ACT for up to 24 hours after administration of a single 1,200-mg dose by binding to and preventing the action of the phospholipid reagents that activate coagulation in commonly used laboratory coagulation tests. Oritavancin has also been shown to elevate D-dimer concentration up to 72 hours after oritavancin administration. ■ Oritavancin does not affect chromogenic factor Xa assay, thrombin time (TT), or tests that are used for the diagnosis of heparin-induced thrombocytopenia (HIT). ■ Oritavancin has no effect on the coagulation system in vivo. ■ In vitro, oritavancin demonstrated synergistic bactericidal activity in combination with gentamicin, linezolid, moxifloxacin, and rifampin against designated organisms.

SIDE EFFECTS

The most common side effects reported are diarrhea, headache, limb and subcutaneous abscesses, and nausea and vomiting. Hypersensitivity and/or infusion reactions and CDAD may be severe. Cellulitis, dizziness, increased ALT and AST levels, infusion site reactions or phlebitis, osteomyelitis, and tachycardia were also reported. Many other side effects occurred in fewer than 1.5% of patients.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated (e.g., diphenhydramine, epinephrine, albuterol) and resuscitate as necessary. Temporarily discontinue or slow infusion for infusion-related reactions. Mild cases of CDAD may respond to discontinuation of oritavancin. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. If osteomyelitis is suspected or diagnosed, institute appropriate alternate antibacterial therapy. Oritavancin is not removed by hemodialysis.

ORPHENADRINE CITRATE

(or-**FEN**-ah-dreen **SIT**-rayt)
Norflex
Skeletal muscle relaxant
(central acting)
pH 5 to 6

USUAL DOSE

60 mg (2 mL) every 12 hours. Transfer to oral formulation for maintenance therapy.

DILUTION

May be given undiluted.

Storage:

Store at CRT. Protect from light.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

60 mg or fraction thereof over 2 to 5 minutes.

ACTIONS

A compound that is structurally similar to diphenhydramine. Possesses anticholinergic effects. Exact mechanism of action is unknown but may be related to its analgesic properties. Does not directly relax tense skeletal muscles. Onset of action is immediate. Half-life of parent compound is 14 hours. Metabolized in the liver. Excreted in feces and urine.

INDICATIONS AND USES

An adjunct to rest, physical therapy, and other measures for the relief of discomfort associated with acute, painful musculoskeletal conditions.

CONTRAINDICATIONS

Bladder neck obstruction, cardiospasm, glaucoma, hypersensitivity to orphenadrine citrate or its components (contains bisulfites), myasthenia gravis, prostatic hypertrophy, pyloric or duodenal obstruction, stenosing peptic ulcer.

PRECAUTIONS

Equal effectiveness produced by IM or oral route. Use IV only when necessary for rapid onset of action. ■ Use caution in tachycardia, cardiac arrhythmias, cardiac decompensation, and coronary insufficiency. ■ Norflex contains sulfites; use caution in patients with allergies. ■ Safety of continuous long-term use not established. ■ Has been chronically abused for its euphoric effects. ■ Mood-elevating effects may occur at therapeutic doses. ■ See Drug/Lab Interactions.

Monitor:

Keep patient in recumbent position for at least 15 minutes to avoid postural hypotension. ■ Periodic monitoring of blood, urine, and liver function recommended with long-term therapy.

Patient Education:

Avoid alcohol and other CNS depressants. ■ May cause dizziness, drowsiness, syncope, and visual disturbances. ■ Request assistance for ambulation. ■ Use caution in any task requiring alertness.

Maternal/Child:

Category C: effects on fetus unknown. Use during pregnancy only if clearly needed. ■ Safety for use during breast-feeding unknown. ■ Safety for use in pediatric patients not established.

Elderly:

May cause confusion. ■ May be more sensitive to anticholinergic effects (dry mouth, urinary retention). ■ Consider age-related renal impairment.

DRUG/LAB INTERACTIONS

Absorption of many **oral drugs inhibited or potentiated** due to decreased GI motility. ■ Potentiates **anticholinergic drugs** (e.g., amantadine). ■ Inhibits **phenothiazines** (e.g., prochlorperazine [Compazine]).

SIDE EFFECTS

Usually associated with higher doses or too-rapid administration: agitation, blurred vision, constipation, dizziness, drowsiness, dry mouth, hallucinations, headache, increased ocular tension, light-headedness, nausea, palpitations, pruritus, pupil dilation, tachycardia, tremor, urinary hesitancy or retention, urticaria, vomiting, weakness. Hypersensitivity reactions, including anaphylaxis (rare), can occur.

Overdose:

Primarily induces serious anticholinergic effects. Range of toxicity is variable and unpredictable.

ANTIDOTE

Notify the physician of any side effects. Reduction of dosage will probably relieve them. Discontinue the drug and treat hypersensitivity symptomatically. Overdose requires intensive monitoring and treatment of emergent anticholinergic effects. Resuscitate as necessary.

OXACILLIN SODIUM

(ox-ah-**SILL**-in **SO**-dee-um)
Bactocill
Antibacterial (penicillinase-resistant penicillin)
pH 6 to 8.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Mild to moderate infections:

250 to 500 mg every 4 to 6 hours.

Severe infections:

Increase to 1 Gm every 4 to 6 hours. Duration of therapy varies with the type and severity of infection as well as the overall condition of the patient. Continue therapy for at least 48 hours after patient becomes afebrile and asymptomatic and cultures are negative. Usual duration of therapy is at least 14 days for severe staphylococcal infections and longer for endocarditis and osteomyelitis. Oral therapy with a penicillinase-resistant penicillin may be used to follow up the parenteral therapy as soon as the clinical condition warrants.

Native valve staphylococcal endocarditis (unlabeled):

2 Gm every 4 hours for 4 to 6 weeks. Gentamicin 1 mg/kg IV or IM every 8 hours has been given concomitantly for the first 3 to 5 days of treatment.

Prosthetic valve staphylococcal endocarditis (unlabeled):

2 Gm every 4 hours for 6 weeks or longer. Given concomitantly with gentamicin 1 mg/kg IV or IM every 8 hours for the first 2 weeks of treatment and rifampin 300 mg orally every 8 hours for 6 weeks or longer.

PEDIATRIC DOSE

Pediatric patients weighing 40 kg or more:

See Usual Dose.

Pediatric patients weighing less than 40 kg:

Mild to moderate infections:

50 mg/kg of body weight/24 hr in equally divided doses every 6 hours (12.5 mg/kg of body weight every 6 hours).

Severe infections:

Increase to 100 to 200 mg/kg/24 hr in equally divided doses every 4 to 6 hours (16.7 to 33.3 mg/kg every 4 hours or 25 to 50 mg/kg every 6 hours).

Native valve staphylococcal endocarditis (unlabeled):

200 mg/kg daily in divided doses every 4 to 6 hours (33.33 mg/kg every 4 hours or 50 mg/kg every 6 hours) for 4 to 6 weeks. Maximum daily dose is 12 Gm. Gentamicin 1 mg/kg IV or IM every 8 hours has been given concomitantly for the first 3 to 5 days of treatment. Adjust gentamicin dose to achieve peak concentration levels of 3 mcg/mL and trough concentration levels of less than 1 mcg/mL.

Prosthetic valve staphylococcal endocarditis (unlabeled):

200 mg/kg daily in divided doses every 4 to 6 hours (33.33 mg/kg every 4 hours or 50 mg/kg every 6 hours) for 6 weeks or longer. Maximum daily dose is 12 Gm. Given concomitantly with gentamicin 1 mg/kg IV or IM every 8 hours (3 mg/kg daily) for the first 2 weeks of treatment (adjust gentamicin dose to achieve peak concentration levels of 3 mcg/mL and trough concentration levels to less than 1 mcg/mL) and oral rifampin

6.7 mg/kg every 8 hours (20 mg/kg daily) for 6 weeks or longer.

NEONATAL DOSE

Under 1,200 Gm; under 7 days of age:

25 mg/kg every 12 hours.

2,000 Gm or less; under 7 days of age:

25 to 50 mg/kg every 12 hours.

2,000 Gm or more; under 7 days of age:

25 to 50 mg/kg every 8 hours.

Under 1,200 Gm; 1 to 4 weeks of age:

25 mg/kg every 12 hours.

2,000 Gm or less; 1 to 4 weeks of age:

25 to 50 mg/kg every 8 hours.

2,000 Gm or more; 1 to 4 weeks of age:

25 to 50 mg/kg every 6 hours.

DOSE ADJUSTMENTS

Decreased dose may be required in severe renal impairment.

DILUTION

Reconstitute each 1-Gm vial with 10 mL of SWFI or NS for injection. Concentration equals 100 mg/mL. May be given by IV injection or may be further diluted for intermittent or continuous infusion in 50 to 1,000 mL of D5W, D5NS, NS, LR, or other **compatible** IV solutions to a final concentration of 0.5 to 4 mg/mL (see literature or chart on inside back cover). Also available prediluted in dextrose (Galaxy frozen solutions) and in ADD-Vantage vials for use with ADD-Vantage infusion containers.

Filter:

Information not available.

Storage:

Store dry powder at CRT. 100 mg/mL solution reconstituted in SWFI or NS is stable for 4 days at RT, 7 days when refrigerated, and 30 days when frozen. Diluted solution stable for at least 6 hours. See literature. Store Galaxy premixed frozen solutions at or below −20° C (−4° F). Thaw at RT or under refrigeration. Do not force thaw. Thawed Galaxy solutions may be stored for 21 days refrigerated or for 48 hours at RT. Do not refreeze.

COMPATIBILITY

Manufacturer states, “Do not physically mix with other agents.” May degrade in infusion solutions containing acidic agents. Inactivated in solution with aminoglycosides (e.g., amikacin, gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. See Drug/Lab Interactions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Too-rapid rate may cause seizures.

IV injection:

1 Gm (10 mL) or fraction thereof slowly over 10 minutes.

Intermittent IV:

A single dose over 10 to 30 minutes.

Infusion:

May be administered in specific IV solutions (check literature) over up to a 6-hour period.

ACTIONS

A semi-synthetic penicillinase-resistant penicillin used for its bactericidal activity against gram-positive organisms, primarily penicillinase-producing *Staphylococcus aureus*. Exerts a bactericidal action against penicillin-susceptible microorganisms during the state of active multiplication. All penicillins inhibit the biosynthesis of the bacterial cell wall. Highly resistant to inactivation by staphylococcal penicillinase. Readily distributes into most body fluids and tissues except cerebrospinal fluid and aqueous humor. Binds to serum proteins, primarily albumin. Excreted primarily as unchanged drug in urine. Nonrenal elimination includes hepatic inactivation and excretion in bile. Half-life is 30 minutes. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Infection caused by strains of penicillinase-producing staphylococci that have demonstrated susceptibility to the drug.

Unlabeled use:

Treatment of staphylococcal endocarditis.

CONTRAINDICATIONS

Known sensitivity to any penicillin or cephalosporin (not absolute; see Precautions). Pre-diluted solutions containing dextrose may be contraindicated in patients with known allergies to corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients undergoing penicillin therapy; most likely to occur in patients with a history of penicillin hypersensitivity or sensitivity to multiple allergens. ■ There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Cross-sensitivity among beta-lactam antibacterial agents has been established; however, the actual incidence of cross-allergenicity is not established. ■ Sensitivity studies necessary to determine susceptibility of the causative organism to oxacillin. It should not be used in infections caused by an organism susceptible to penicillin G or an organism other than a resistant staphylococcus. Modify antimicrobial therapy as indicated by C/S. ■ Resistance to oxacillin (or cefoxitin [a surrogate for oxacillin in susceptibility testing]) implies resistance to all other beta-lactam agents, except newer agents with activity against methicillin-resistant *Staphylococcus aureus*. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, oxacillin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Superinfection caused by overgrowth of nonsusceptible organisms is a possibility. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with oxacillin.

Monitor:

Obtain blood culture and baseline WBC and differential before initiating therapy and repeat weekly. Periodic liver, kidney, and hematopoietic studies are advised. Monitor urinalysis, BUN and SCr; reduced dose may be indicated with signs of renal impairment. Monitor AST (SGOT), ALT (SGPT) periodically. ■ Electrolyte imbalance and cardiac irregularities from sodium content are possible. Contains up to 4.02 mEq sodium/Gm. May aggravate CHF. ■ May cause thrombophlebitis, especially in the elderly; observe carefully and rotate infusion sites. ■ See Drug/Lab Interactions.

Patient Education:

Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Promptly report S/S of a hypersensitivity reaction (e.g., pruritus, rash, shortness of breath, wheezing).

Maternal/Child:

Use during pregnancy only if clearly needed. ■ Use caution in breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. All pediatric patients should be monitored for evidence of toxic or adverse effects. Limited experience in use on premature infants and neonates. Use with caution. Elimination rate markedly reduced in neonates.

Elderly:

Response similar to that seen in younger patients. Consider age-related organ impairment and concomitant disease or drug therapy. Elderly patients may respond with a blunted natriuresis to salt loading. May be clinically important with regard to diseases such as CHF. ■ See Precautions/Monitor and Dose Adjustments.

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **aminoglycosides** (e.g., amikacin, gentamicin, tobramycin). Synergism may be inconsistent; see Compatibility. ■ **Tetracyclines** may antagonize the bactericidal action of penicillin; avoid concurrent administration. ■ **Probenecid** blocks the renal tubular secretion, decreasing elimination and increasing serum concentrations; toxicity may result. Penicillin-probenecid therapy is generally limited to infections in which very high serum levels of penicillin are necessary.

SIDE EFFECTS

Hypersensitivity reactions, including anaphylaxis, may be very immediate (usually occurring within 20 minutes of administration and ranging in severity from pruritus and urticaria to angioneurotic edema, bronchospasm, hypotension, laryngospasm, vascular collapse, and death) or moderately immediate (occurring between 20 minutes and 48 hours after administration; fever, hypotension, laryngeal edema, laryngospasm, pruritus, and urticaria may occur, and fatality is uncommon). Delayed hypersensitivity reactions may occur after 48 hours or up to 2 to 4 weeks after beginning therapy, and manifestations include serum sickness–like symptoms (e.g., abdominal pain, arthralgia, fever, malaise, myalgia, skin rashes, urticaria). CDAD, elevated AST, hepatic dysfunction, interstitial nephritis (may include eosinophilia, fever, hematuria, proteinuria, renal insufficiency and rash), nausea, pruritus, renal tubular damage, skin rash, thrombophlebitis, transient hematuria in newborns, urticaria, and vomiting can occur. Higher-than-normal doses may cause neurologic adverse reactions, including convulsions, especially with impaired renal function.

ANTIDOTE

Notify the physician of any adverse symptoms. For severe symptoms, discontinue the drug, treat hypersensitivity reactions (antihistamines, epinephrine, corticosteroids), and resuscitate as necessary. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated.

OXALIPLATIN BBW

(**OX**-al-ee-**plah**-tin)
Eloxatin
Antineoplastic

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies required; see Monitor.

Both indications:

Given in combination with 5-FU and leucovorin calcium in a dose schedule that repeats every 2 weeks. When used as adjuvant therapy in patients with stage III colon cancer, a treatment period repeated every 2 weeks for 6 months is recommended (a total of 12 cycles). For advanced disease, treatment is recommended until disease progression or unacceptable toxicity. For information on 5-FU and leucovorin calcium, see respective monographs. Prehydration is not required. Premedication with antiemetics recommended; see Monitor. Some clinicians are administering magnesium and calcium before and after oxaliplatin to decrease neurotoxicity.

Day 1:

Oxaliplatin 85 mg/M^2 and leucovorin calcium 200 mg/M^2, both given as an IV infusion over 120 minutes at the same time in separate bags using a Y-line. Follow with 5-FU 400 mg/M^2 IV bolus given over 2 to 4 minutes, followed by 5-FU 600 mg/M^2 in 500 mL D5W (recommended) as a 22-hour continuous infusion.

Day 2:

Leucovorin calcium 200 mg/M^2 IV infusion over 120 minutes. Follow with 5-FU 400 mg/M^2 IV bolus given over 2 to 4 minutes, followed by 5-FU 600 mg/M^2 in 500 mL D5W (recommended) as a 22-hour continuous infusion.

DOSE ADJUSTMENTS

Decrease starting dose to 65 mg/M^2 in patients with severe renal impairment (CrCl less than 30 mL/min). ■ Withhold oxaliplatin for sepsis or septic shock, and reduce dose if indicated as outlined in the following sections.

Advanced colorectal cancer:

Dose adjustments are based on clinical toxicities. Reduce dose of oxaliplatin to 65 mg/M^2 in patients who experience persistent Grade 2 neurosensory events that do not resolve. (See Monitor for study-specific neurotoxicity scale.) The infusional 5-FU/leucovorin calcium regimen need not be altered. ■ Reduce dose of oxaliplatin to 65 mg/M^2 and 5-FU to a 300 mg/M^2 bolus and 500 mg/M^2 as a 22-hour infusion in patients who develop Grade 3 or 4 gastrointestinal toxicity (despite prophylactic treatment), Grade 4 neutropenia, febrile neutropenia, or Grade 3 or 4 thrombocytopenia. Delay next dose until neutrophils are greater than or equal to 1.5×10^9/L [1,500 cells/mm^3] and platelets are greater than or equal to 75×10^9/L [75,000 cells/mm^3]).

Adjuvant therapy in stage III colon cancer (postoperative):

Reduce dose of oxaliplatin to 75 mg/M^2 in patients who experience persistent Grade 2 neurosensory events that do not resolve (NCICTC scale version 1 used). The infusional 5-FU/leucovorin calcium regimen need not be altered. ■ Reduce dose of oxaliplatin to 75 mg/M^2 and 5-FU to a 300 mg/M^2 bolus and 500 mg/M^2 as a 22-hour infusion in patients who develop Grade 3 or 4 gastrointestinal toxicity (despite prophylactic treatment), Grade 4 neutropenia, febrile neutropenia, or Grade 3 or 4 thrombocytopenia. Delay next dose until neutrophils are greater than or equal to 1.5 × 10^9/L (1,500 cells/mm^3) and platelets are greater than or equal to 75 × 10^9/L (75,000 cells/mm^3).

Both indications:

Consider discontinuing therapy in patients with persistent Grade 3 neurosensory events.

DILUTION

Specific techniques required; see Precautions.

Do not reconstitute or dilute with a sodium chloride solution (e.g., NS, ½NS, ¼NS) or other chloride-containing solutions. Available as a concentrate for solution. The concentrate for solution must be further diluted with 250 to 500 mL of D5W. ***Do not use NS or any chloride-containing solutions; see Compatibility.*** Do not use needles or administration sets with aluminum parts; a precipitate may form, and potency may decrease.

Storage:

Store vials with concentrate in the original carton at CRT. Protect vials with concentrate from light and do not freeze. After final dilution with 250 to 500 mL of D5W, the solution may be stored for up to 6 hours at RT (20° to 25° C [68° to 77° F]) or up to 24 hours under refrigeration.

COMPATIBILITY

Manufacturer states oxaliplatin "is **incompatible** in solution with alkaline medications or media (such as basic solutions of 5-FU) and must not be mixed with these or administered simultaneously through the same infusion line. *The infusion line should be flushed with D5W prior to administration of any concomitant medication.*" Reconstitution or final dilution must not be performed with a sodium chloride solution or other chloride-containing solutions. Do not use needles or administration sets with aluminum parts; a precipitate may form, and potency may decrease.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

The infusion line should be flushed with D5W prior to administration of any concomitant medication.

Day 1:

Oxaliplatin and leucovorin calcium are given as infusions and equally distributed over 120 minutes. Given at the same time in separate bags using a Y-line. When complete, flush the IV line with D5W. Follow with a **5-FU bolus** administered over 2 to 4 minutes, followed by a **5-FU continuous infusion** equally distributed over 22 hours. ■ Increasing the infusion time of oxaliplatin from 2 to 6 hours may mitigate acute toxicities. The infusion times for 5-FU and leucovorin calcium need not be altered.

Day 2:

Leucovorin calcium is given as an infusion equally distributed over 120 minutes. Follow with a **5-FU bolus** administered over 2 to 4 minutes, followed by a **5-FU continuous infusion** equally distributed over 22 hours.

ACTIONS

A platinum-based antineoplastic agent. Undergoes nonenzymatic conversion to active derivatives that inhibit DNA replication and transcription. Cytotoxicity is cell-cycle nonspecific. Rapidly distributed into tissues or eliminated in the urine. Highly protein bound. Undergoes rapid and extensive nonenzymatic biotransformation. No evidence of cytochrome P_{450}-mediated metabolism. Major route of elimination is renal excretion.

INDICATIONS AND USES

Used in combination with infusional 5-FU and leucovorin calcium for the treatment of patients with advanced colorectal cancer and for adjuvant therapy of stage III colon cancer patients who have undergone complete resection of the primary tumor.

CONTRAINDICATIONS

Hypersensitivity to oxaliplatin or other platinum-containing compounds (e.g., carboplatin, cisplatin).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities and emergency resuscitation equipment and supplies must always be available. ■ Hypersensitivity and anaphylactic-like reactions, some fatal, have been reported and may occur within minutes of administration and during any cycle. Rechallenge is contraindicated. See Side Effects and Antidote. ■ Use with caution in patients with renal impairment; see Dose Adjustments. ■ Associated with two types of neuropathy. *The first type is an acute, reversible, primarily peripheral sensory neuropathy that is of early onset, occurs within hours or 1 to 2 days of dosing, resolves within 14 days, and frequently recurs with further dosing*. Symptoms may be precipitated or exacerbated by exposure to cold temperature or cold objects. Usually presents as transient paresthesia (abnormal sensation [e.g., burning, prickling]), dysesthesia (decreased sensitivity to stimulation), and hypoesthesia (impairment of any sense, especially touch) in the hands, feet, perioral area, or throat. *The second type is a* *persistent (lasting more than 14 days), primarily peripheral, sensory neuropathy that is usually characterized by paresthesias, dysesthesias, and hypoesthesias but may also include deficits in proprioception (stimulus of the sensory end organs [e.g., muscles, tendons]), which can interfere with daily activities (e.g., writing, buttoning, swallowing, and walking).* May occur without any prior acute neuropathy event. Symptoms may or may not improve with discontinuation of oxaliplatin. ■ Reversible posterior leukoencephalopathy syndrome (RPLS, also known as PRES [posterior reversible encephalopathy syndrome]) has been reported; see Monitor. ■ Grade 3 or 4 neutropenia has occurred in patients treated with oxaliplatin. Sepsis, neutropenic sepsis, and septic shock have been reported. Deaths have occurred; see Dose Adjustments. ■ Has been associated with pulmonary fibrosis, which may be fatal; see Monitor. ■ Hepatotoxicity has been reported; see Monitor. ■ QT prolongation and ventricular arrhythmias, including fatal torsades de pointes, have been reported. Avoid oxaliplatin in patients with congenital long QT syndrome; see Monitor and Drug/Lab Interactions. ■ Rhabdomyolysis, including fatal cases, has been reported. ■ See Drug/Lab Interactions.

Monitor:

CBC with differential, platelet count, and blood chemistries (including ALT, AST, bilirubin, and creatinine) are recommended before each cycle. See Dose Adjustments and Precautions. ■ Monitor for S/S of a hypersensitivity reaction (e.g., bronchospasm, chest pain, diaphoresis, diarrhea associated with oxaliplatin infusion, disorientation, erythema, flushing, hypotension, pruritus, rash, shortness of breath, syncope, urticaria). ■ Monitor for S/S of RPLS; may include abnormal vision from blurriness to blindness, altered mental functioning, headache, or seizures with or without associated hypertension. Diagnosis of RPLS is based on confirmation by brain imaging. ■ Monitor for unexplained respiratory symptoms such as nonproductive cough, dyspnea, crackles, or radiologic pulmonary infiltrates. Discontinue oxaliplatin until pulmonary investigation rules out interstitial lung disease or pulmonary fibrosis. ■ Monitor for S/S of neuropathy (e.g., transient paresthesia [abnormal sensation (e.g., burning, prickling)], dysesthesia [decreased sensitivity to stimulation], and hypoesthesia [impairment of any sense, especially touch] in the hands, feet, perioral area, or throat). Neurotoxicity scale used during advanced colorectal cancer studies differed from National Cancer Institute toxicity grading. Grading scale for paresthesias/dysesthesias was as follows: Grade 1, resolved and did not interfere with functioning; Grade 2, interfered with function but not daily activities; Grade 3, pain or functional impairment that interfered with daily activities; Grade 4, persistent impairment that is disabling or life threatening. ■ Nausea and vomiting may be significant. Prophylactic administration of antiemetics, including $5HT_3$ blockers (e.g., ondansetron [Zofran]), with or without dexamethasone (Decadron), is recommended. ■ Observe closely for signs of infection, sepsis, or septic shock. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for S/S of hepatotoxicity. Hepatic vascular disorders should be considered in the case of abnormal liver function test results or portal hypertension that cannot be explained by liver metastases. ■ ECG monitoring is recommended for patients with CHF, bradyarrhythmias, drugs known to prolong the QT interval, and electrolyte abnormalities. Correct hypokalemia and hypomagnesemia before initiating oxaliplatin therapy, and monitor these electrolytes periodically during therapy; see Drug/Lab Interactions. ■ Monitor for S/S of rhabdomyolysis (muscle pain, weakness, dark urine, elevation in creatinine kinase [CK] and other serum muscle enzymes).

Patient Education:

Avoid pregnancy. Effective birth control recommended. ■ Report any neurologic symptoms (e.g., confusion or a change in the way you think; headache; numbness, pain, or tingling in extremities; seizures; sensitivity to cold; troubled breathing or swallowing; vision problems). Acute neurosensory toxicity may be precipitated or exacerbated by exposure to cold. Avoid cold drinks and use of ice. Cover exposed skin before exposure to cold temperature. ■ Promptly report persistent vomiting, diarrhea, breathing difficulty, cough, or any sign of infection, allergic reaction, or dehydration. ■ Use caution while driving or using machines; neurologic symptoms (e.g., dizziness), nausea and vomiting, and vision abnormalities (e.g., transient vision loss) may interfere with abilities. ■ Manufacturer supplies a patient information leaflet; read before taking oxaliplatin. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: avoid pregnancy; may cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Has been studied in a small number of solid tumors in pediatric patients. No significant response was observed. See manufacturer’s literature.

Elderly:

The overall rates of adverse events, including Grade 3 and 4 events, were similar for all age-groups. However, the incidence of dehydration, diarrhea, fatigue, Grade 3 to 4 granulocytopenia, hypokalemia, leukopenia, and syncope were higher in patients 65 years of age or older. Adjustment of starting dose is not required.

DRUG/LAB INTERACTIONS

Formal studies have not been performed. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents. ■ Platinum-containing species are eliminated primarily through the kidney; clearance of these products may be decreased by coadministration of potentially **nephrotoxic compounds** (e.g., aminoglycosides [e.g., gentamicin], amphotericin B [all formulations], NSAIDs [e.g., ibuprofen, naproxen], pamidronate, tacrolimus). ■ Oxaliplatin is not metabolized by, nor does it inhibit, cytochrome P_{450} isoenzymes. P_{450}-mediated interactions are not anticipated. ■ A prolonged PT and INR (occasionally associated with hemorrhage) has been reported when oxaliplatin is used concomitantly with **anticoagulants** (e.g., warfarin); close monitoring of PT and INR recommended. ■ Use caution when administered with **drugs known to prolong the QT interval** (e.g., Class Ia and III antiarrhythmics [e.g., disopyramide, procainamide, quinidine, amiodarone], macrolide antibiotics [e.g., azithromycin, clarithromycin], fluoroquinolones [e.g., ciprofloxacin, levofloxacin], antiemetics [e.g., dolasetron, ondansetron]). ECG monitoring recommended.

SIDE EFFECTS

Are frequent and numerous. The most common adverse reactions are anemia, diarrhea, fatigue, increased liver function tests (e.g., alkaline phosphatase, total bilirubin, and transaminases), nausea, neutropenia, peripheral sensory neuropathies, stomatitis, thrombocytopenia, and vomiting; see Precautions. Other reported reactions include abdominal pain, alopecia, angioedema, anorexia, arthralgia, back pain, chest pain, conjunctivitis, constipation, coughing, deafness, dehydration, dizziness, dyspepsia, dyspnea, dysuria, edema, elevated serum creatinine, epistaxis, fever, flushing, gastroesophageal reflux, hand-foot syndrome, headache, hematuria, hemolytic uremic syndrome, hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, erythema, hypotension, laryngospasm, pruritus, rash, urticaria), hypertension, hypokalemia, immunoallergic hemolytic anemia, infection, injection site reaction, insomnia, intestinal obstruction, lacrimation abnormalities, metabolic acidosis, mucositis, pain, pancreatitis, persistent vomiting, pharyngitis, pulmonary fibrosis, rhinitis, rigors, secondary malignancies, taste perversion, thromboembolism, veno-occlusive disease of the liver, visual disorders (e.g., decrease of visual acuity, visual field disturbance, optic neuritis), weight gain. Many other side effects have been reported and may occur.

Overdose:

Chest pain, dehydration, diarrhea, dyspnea, enlarged abdomen and Grade 4 intestinal obstruction, hypersensitivity reactions, myelosuppression, nausea and vomiting, neurotoxicity, paresthesia, respiratory failure, severe bradycardia, stomatitis, wheezing, and death.

Post-Marketing:

Acute interstitial nephritis, acute renal failure, acute tubular necrosis, colitis (including *Clostridium difficile* diarrhea), convulsions, cranial nerve palsies, dysarthria, fasciculations, hemolytic uremic syndrome, ileus, immunoallergic hemolytic anemia, Lhermitte's sign, loss of deep tendon reflexes, metabolic acidosis, perisinusoidal fibrosis, pulmonary fibrosis and other interstitial lung diseases (sometimes fatal), QT prolongation leading to ventricular arrhythmias (including fatal torsades de pointes), rhabdomyolysis (including fatal outcomes), reversible posterior leukoencephalopathy syndrome (RPLS), septic shock (including fatal cases), severe diarrhea/vomiting resulting in hypokalemia, transient vision loss (reversible after oxaliplatin is discontinued).

ANTIDOTE

Notify physician of all side effects. Oxaliplatin may need to be discontinued permanently or until recovery. Slowing of infusion rate may help mitigate acute toxicities. Symptomatic and supportive treatment is indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen, Zarxio], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Treat anaphylaxis with epinephrine, corticosteroids, oxygen, and antihistamines (diphenhydramine). There is no specific antidote. Resuscitate as indicated.

OXYTOCIN INJECTION BBW

(ox-eh-**TOE**-sin in-**JEK**-shun)
Pitocin
Oxytocic
Antihemorrhagic
pH 2.5 to 4.5

USUAL DOSE

Determined by uterine response and intended use, dilution, and rate of administration. Dose must be individualized and initiated at a very low level. Piggyback oxytocin into a physiologic electrolyte IV solution (e.g., NS) without oxytocin; see Precautions.

Induction of labor:

0.5 to 1 milliunits/min (equal to 3 to 6 mL/hr of properly diluted solution). See Dilution and Rate of Administration.

Control of postpartum bleeding:

See Dilution and Rate of Administration.

Incomplete, inevitable, or elective abortion:

A total of 10 milliunits delivered at 10 to 20 milliunits/min. A total dose should not exceed 30 milliunits in a 12-hour period due to the risk of water intoxication. See Dilution and Rate of Administration.

DILUTION

In all situations, rotate gently to distribute medication through solution.

Induction of labor:

Dilute 1 mL (10 milliunits) in 1 liter of NS or LR for infusion (10 milliunits/mL).

Control of postpartum bleeding:

Dilute 1 to 4 mL (10 to 40 milliunits) in 1 liter of above infusion fluids (10 to 40 milliunits/mL).

Incomplete, inevitable, or elective abortion:

Dilute 1 mL (10 milliunits) in 500 mL of NS or D5W.

Storage:

Store at CRT.

COMPATIBILITY

Rapidly decomposes in the presence of sodium bisulfate.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Given only as an IV infusion. Use of an infusion pump or other accurate control device is required. In all situations, use the minimum effective rate and monitor strength, frequency, and duration of contractions; resting uterine tone; fetal HR (in induction of labor); and maternal BP; see Monitor.

Induction of labor:

Begin with 0.5 to 1 milliunits/min (3 to 6 mL/hr), and increase in increments of 1 to 2 milliunits/min at 30- to 60-minute intervals until contractions simulate normal labor. Maximum dose rarely exceeds 9 to 10 milliunits/min at term; average is 2 to 5 milliunits/min. Reduce by similar increments when desired frequency of contractions is reached and labor has progressed to 5 to 6 cm. 6 milliunits/min provides oxytocin levels similar to spontaneous labor. Preterm induction may require somewhat higher doses due to a lower concentration of oxytocin receptors; use caution.

Control of postpartum bleeding:

Adjust rate of infusion to sustain contractions and control uterine atony.

Incomplete, inevitable, or elective abortion:

10 to 20 milliunits/min. Total dose should not exceed 30 milliunits in a 12-hour period due to the risk of water intoxication.

ACTIONS

A synthetic posterior pituitary hormone that will produce rhythmic contraction of uterine smooth muscle. Has specific receptors in the myometrium, and the receptor concentration increases greatly during pregnancy. Promotes contractions by increasing the intracellular calcium. Distributed throughout the extracellular fluid. Onset of action is almost immediate. Half-life is 1 to 6 minutes. Duration of action is approximately 1 hour. Is the drug of choice for induction of delivery. Rapidly removed from plasma via liver and kidney. Only small amounts are excreted in urine unchanged. May exhibit antidiuretic and pressor effects at higher doses. Probably crosses the placental barrier in small amounts.

INDICATIONS AND USES

Antepartum:

Indicated for the initiation or improvement of uterine contractions (when these are desirable and considered suitable for reasons of fetal or maternal concern) in order to achieve vaginal delivery. Indicated for (1) induction of labor in patients with a medical indication (e.g., Rh problems, maternal diabetes, pre-eclampsia at or near term) or when membranes are prematurely ruptured and delivery is indicated; (2) stimulation or reinforcement of labor, as in selected cases of uterine inertia; and (3) as adjunctive therapy in the management of incomplete or inevitable abortion. In the first trimester, curettage is generally considered primary therapy. In second-trimester abortion, oxytocin infusion will often be successful in emptying the uterus. However, other means of therapy may be required.

Postpartum:

Indicated to produce uterine contractions during the third stage of labor and to control postpartum bleeding or hemorrhage. ■ Not indicated for elective induction of labor (i.e., the initiation of labor in a pregnant individual who has no medical indication for induction).

CONTRAINDICATIONS

Cephalopelvic disproportion, fetal malpresentation, hypersensitivity, hypertonic uterine contractions, lack of satisfactory progress with adequate uterine activity, obstetrical emergencies in which the benefit-to-risk ratio for either the fetus or the mother favors surgical intervention (e.g., abruptio placentae), or when vaginal delivery is contraindicated (e.g., active herpes genitalis, cord presentation or prolapse, invasive cervical carcinoma, total placenta previa and vasa previa). See Precautions.

PRECAUTIONS

A NS IV without oxytocin should be hung, connected by Y-tube or three-way stopcock, and ready for use in adverse reactions. ■ Should be administered only in the hospital under continuous observation by trained personnel; the physician must be immediately available. ■ The use of oxytocin for fetal distress, hydramnios, partial placenta previa, prematurity, borderline cephalopelvic disproportion, or any condition that may cause uterine rupture (e.g., previous major surgery on the cervix or uterus, including cesarean section, uterine overdistension, grand multiparity, or past history of uterine sepsis or traumatic delivery) is not recommended except in unusual circumstances. ■ Maternal deaths due to hypertensive episodes, subarachnoid hemorrhage, and uterine rupture, as well as fetal deaths due to various causes, have been reported. ■ When used for induction or reinforcement of already existing labor, patients should be carefully selected. Evaluate pelvic adequacy and maternal and fetal conditions before use.

Monitor:

When properly administered, oxytocin should stimulate uterine contractions comparable to normal labor. Monitor BP, fetal heart tones, strength and timing of contractions, and resting uterine tone. Continuous observation of patient required. ■ Electronic fetal monitoring provides the best means of early detection of overdose. A fetal scalp electrode provides a more accurate recording of fetal HR than external monitoring. ■ Has an intrinsic antidiuretic effect, increasing water reabsorption from the glomerular filtrate. Monitor oral fluid intake and observe for signs of water intoxication. ■ See Precautions and Drug/Lab Interactions.

Maternal/Child:

There is no indication for use in the first trimester of pregnancy other than in relation to spontaneous or induced abortion. Not expected to present a risk if used as indicated; see Indications and Contraindications.

DRUG/LAB INTERACTIONS

Severe hypertension can result in the presence of a **vasoconstrictor** given in conjunction with a **local or regional anesthetic** (caudal or spinal) **and with dopamine, ephedrine, epinephrine, and other vasopressors.** ■ Concurrent use with **cyclopropane anesthesia** may cause hypotension and/or sinus bradycardia with abnormal atrioventricular rhythms. ■ **Prostaglandins** (e.g., dinoprostone) may potentiate the uterine response to oxytocin, increasing the risk of uterine hyperstimulation and rupture.

SIDE EFFECTS

Maternal:

Anaphylaxis; cardiac arrhythmias; fatal afibrinogenemia; fluid retention leading to water intoxication and coma, convulsion, and death; hypertension; increased blood loss; nausea; pelvic hematoma; postpartum hemorrhage; PVCs; severe uterine hypertonicity, spasm, or tetanic contraction; subarachnoid hemorrhage; uterine rupture; vomiting.

Fetal:

Bradycardia, brain damage, CNS damage, death, low Apgar scores, neonatal jaundice, PVCs and other arrhythmias, retinal hemorrhage, seizures.

ANTIDOTE

Nausea and vomiting are tolerable and can be treated symptomatically. Immediately call the physician’s attention to any side effect noted or suspected; many can be fatal. Discontinue the drug immediately for any signs of fetal distress, uterine hyperactivity, tetanic contractions, uterine resting tone exceeding 15 to 20 mm Hg, or water intoxication. Use of a Y-connection or three-way stopcock, allowing the oxytocin drip to be discontinued while the vein is kept open, is recommended. Turn mother on side (to prevent fetal anoxia) and administer oxygen. Restriction of fluids, diuresis, hypertonic saline solutions IV, correction of electrolyte imbalance, control of convulsions with cautious use of barbiturates, or the use of magnesium sulfate may be required. These side effects can occur during labor and delivery and into the postpartum period. Careful evaluation and selection of patients eliminate many hazards, but be prepared for an emergency.

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies required; see Monitor and Dose Adjustments.

Conventional Paclitaxel

Several regimens of paclitaxel, alone or in combination with other antineoplastics, are in use. Doses vary, depending on the regimen used. Consult literature. ■ For all uses, premedication, specific parameters, and specific equipment are required before or during administration; see Premedication, Dose Adjustments, and Precautions/Monitor.

Premedication:

Must be premedicated before each dose to prevent severe hypersensitivity reactions. Usual regimen includes oral dexamethasone 20 mg 12 and 6 hours before; IV diphenhydramine 50 mg 30 to 60 minutes before; and an H_2 antagonist (e.g., famotidine 20 mg) 30 to 60 minutes before dosing with paclitaxel. When premedicating patients with AIDS-related Kaposi's sarcoma, reduce the dose of dexamethasone to 10 mg at 12 and 6 hours before paclitaxel. The doses of IV diphenhydramine and IV H_2 antagonists remain as above.

Ovarian cancer in previously untreated patients:

135 mg/M^2 as an infusion over 24 hours. Follow with cisplatin 75 mg/M^2 as an infusion over 6 to 8 hours. Repeat every 3 weeks. An alternative regimen is paclitaxel 175 mg/M^2 as an infusion over 3 hours. Follow with cisplatin 75 mg/M^2 (one source suggests an infusion over 24 hours; another suggests 6 to 8 hours, which would allow for outpatient therapy). Repeat every 3 weeks. See comments under Usual Dose.

Ovarian cancer in patients previously treated with chemotherapy:

135 or 175 mg/M^2 as an infusion over 3 hours. An alternate regimen suggests the same dose given as a 24-hour infusion. Repeat every 3 weeks. Larger doses, with or without filgrastim (G-CSF, Neupogen), have produced similar responses. See comments under Usual Dose.

Adjuvant treatment of node-positive breast cancer:

175 mg/M^2 as an infusion over 3 hours. Repeat every 3 weeks for four courses. Administered sequentially to doxorubicin-containing combination therapy. Clinical trials used four courses of doxorubicin and cyclophosphamide. Administer filgrastim (G-CSF) 5 mcg/kg/dose on Days 3 through 10. See comments under Usual Dose.

Breast cancer in patients previously treated with chemotherapy:

175 mg/M^2 as an infusion over 3 hours. Repeat every 3 weeks. An alternate regimen suggests 175 to 250 mg/M^2 over 3 hours every 3 weeks. See comments under Usual Dose.

First-line treatment of non–small-cell lung cancer:

135 mg/M^2 as an infusion over 24 hours. Follow with cisplatin 75 mg/M^2 over 6 to 8 hours. Repeat every 3 weeks. See comments under Usual Dose. A Canadian source recommends 175 mg/M^2 as an infusion over 3 hours followed with cisplatin 75 mg/M^2 over 6 to 8 hours and repeated every 3 weeks.

AIDS-related Kaposi's sarcoma:

135 mg/M^2 as an infusion over 3 hours. An alternate regimen suggests the same dose given as a 24-hour infusion. Repeat every 3 weeks. Another regimen is 100 mg/M^2 as an infusion over 3 hours repeated every 2 weeks. Toxicity somewhat increased with 135 mg/M^2 dose in clinical studies. See comments under Usual Dose.

Abraxane

Premedication:

Generally not required; see Precautions.

Metastatic breast cancer (MBC):

260 mg/M^2 as an infusion over 30 minutes every 3 weeks.

Non–small-cell lung cancer (NSCLC):

100 mg/M^2 as an infusion over 30 minutes on Days 1, 8, and 15 of each 21-day cycle. Given in combination with carboplatin on Day 1 only of each 21-day cycle, beginning immediately after the completion of Abraxane administration.

Adenocarcinoma of the pancreas:

125 mg/M^2 as an infusion over 30 to 40 minutes followed by gemcitabine 1,000 mg/M^2

as an infusion over 30 to 40 minutes on Days 1, 8, and 15 of each 28-day cycle.

DOSE ADJUSTMENTS

Conventional Paclitaxel

Reduce dose by 20% for subsequent courses in patients who experience severe peripheral neuropathy or severe neutropenia (neutrophils less than 500 cells/mm^3) for 1 week or longer. ■ Withhold therapy if neutrophils below 1,500/mm^3 or platelets below 100,000/mm^3. ■ Dose reduction not required in impaired renal function. ■ In AIDS-related Kaposi's sarcoma the parameters are slightly different. Initiate or repeat paclitaxel only if neutrophil count is equal to or greater than 1,000/mm^3; reduce dose of dexamethasone to 10 mg/dose; reduce dose of paclitaxel by 20% in patients who experience severe neutropenia (neutrophils less than 500/mm^3 for a week or longer); use concomitant filgrastim (G-CSF) as clinically indicated. ■ Recommendations for dose adjustment of the initial course of therapy in patients with impaired hepatic function are listed in the following chart.

Guidelines for Dose Adjustment of Paclitaxel in Impaired Hepatic Function[a]

Degree of Hepatic Impairment			**Recommended TAXOL Dose**[c]
Transaminase Levels		**Bilirubin Levels**[b]	
24-Hour Infusion			
<2 × ULN	and	≤1.5 mg/dL	135 mg/M^2
2 to <10 × ULN	and	≤1.5 mg/dL	100 mg/M^2
<10 × ULN	and	1.6-7.5 mg/dL	50 mg/M^2
≥10 × ULN	or	>7.5 mg/dL	Not recommended
3-Hour Infusion			
<10 × ULN	and	≤1.25 × ULN	175 mg/M^2
<10 × ULN	and	1.26-2 × ULN	135 mg/M^2
<10 × ULN	and	2.01-5 × ULN	90 mg/M^2
≥10 × ULN	or	>5 × ULN	Not recommended

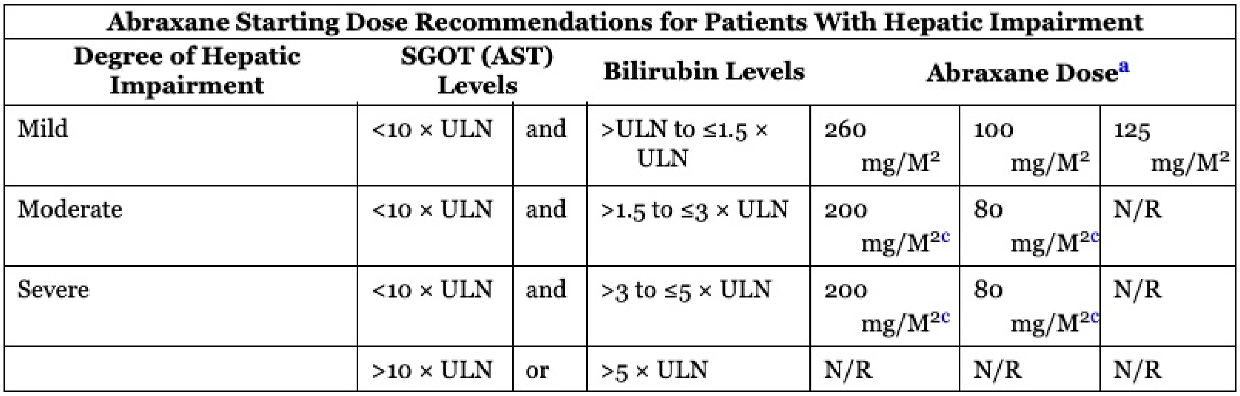
[a] These recommendations are based on clinical trials of dosages for patients without hepatic impairment of 135 mg/M^2 over 24 hours or 175 mg/M^2 over 3 hours; data are not available to make dose adjustment recommendations for other regimens (e.g., for AIDS-related Kaposi's sarcoma).

[b] Differences in criteria for bilirubin levels between the 3- and 24-hour infusion are due to differences in clinical trial design.

[c] Dosage recommendations are for the first course of therapy; further dose reduction in subsequent courses should be based on individual tolerance.

Abraxane

Adjustment of starting dose is not necessary in patients with mild to moderate renal impairment (CrCl equal to or greater than 30 to less than 90 mL/min). ■ Withhold therapy in all patients if neutrophils below 1,500/mm^3. ■ In patients with MBC, withhold therapy if platelets below 100,000/mm^3. ■ For MBC, reduce dose to 220 mg/M^2 in patients who experience severe neutropenia (neutrophils less than 500 cells/mm^3 for 7 days or more) or severe sensory neuropathy. Further reduce dose to 180 mg/M^2 for subsequent courses if severe neutropenia (less than 500 cells/mm^3 for 7 days or more) or severe sensory neuropathy recurs. ■ If Grade 3 sensory neuropathy occurs, withhold treatment until resolution to Grade 1 or 2 for ***MBC*** or until resolution to less than or equal to Grade 1 for ***NSCLC,*** followed by a dose reduction for all subsequent courses. ■ No dose adjustment is necessary for patients with mild hepatic impairment (total bilirubin greater than the ULN and less than or equal to 1.5 times the ULN and AST less than or equal to 10 times the ULN), regardless of indication. ■ Do not administer Abraxane to patients with total bilirubin greater than 5 times the ULN or AST greater than 10 times the ULN regardless of indication because these patients have not been studied. ■ Do not administer Abraxane to patients with metastatic adenocarcinoma of the pancreas who have moderate to severe hepatic impairment. ■ Recommendations for a starting dose in patients with hepatic impairment are shown in the following chart. Doses for subsequent cycles should be based on patient tolerance.



Abraxane Starting Dose Recommendations for Patients With Hepatic Impairment

Degree of Hepatic Impairment	SGOT (AST) Levels		Bilirubin Levels	Abraxane Dose[a]		
Mild	<10 × ULN	and	>ULN to ≤1.5 × ULN	260 mg/M^2	100 mg/M^2	125 mg/M^2
Moderate	<10 × ULN	and	>1.5 to ≤3 × ULN	200 mg/M^2[c]	80 mg/M^2[c]	N/R
Severe	<10 × ULN	and	>3 to ≤5 × ULN	200 mg/M^2[c]	80 mg/M^2[c]	N/R
	>10 × ULN	or	>5 × ULN	N/R	N/R	N/R

MBC, Metastatic breast cancer; *N/R,* not recommended; *NSCLC,* non–small-cell lung cancer.

[a] Dose recommendations are for the first course of therapy. The need for further dose adjustments in subsequent courses should be based on individual tolerance.

[b] Patients with bilirubin levels above the ULN were excluded from clinical trials for pancreatic or lung cancer.

[c] A dose increase to 260 mg/M^2 for patients with MBC or to 100 mg/M^2 for patients with NSCLC in subsequent courses should be considered if the patient tolerates the reduced dose for two cycles.

■ In patients with NSCLC who develop severe neutropenia or thrombocytopenia, withhold therapy until counts recover to an ANC of at least 1,500 cells/mm^3 and platelets of at least 100,000 cells/mm^3 on Day 1 or to an ANC of at least 500 cells/mm^3 and platelets of at least 50,000 cells/mm^3 on Day 8 or 15 of the cycle. Upon resumption of dosing, follow dose reduction outlined in the following chart.

Permanent Abraxane Dose Reductions for Hematologic and Neurologic Adverse Drug Reactions in NSCLC

Adverse Drug Reaction	Occurrence	Weekly Abraxane Dose (mg/M^2)	Every-3-Week Carboplatin Dose (AUC mg•min/mL)
Neutropenic fever (ANC less than 500/mm^3 with fever >38° C) **OR** Delay of next cycle by more than 7 days for ANC less than 1,500/mm^3 **OR** ANC less than 500/mm^3 for more than 7 days	First	75 mg/M^2	4.5 mg•min/mL
	Second	50 mg/M^2	3 mg•min/mL
	Third	Discontinue treatment	Discontinue treatment
Platelet count less than 50,000/mm^3	First	75 mg/M^2	4.5 mg•min/mL
	Second	Discontinue treatment	Discontinue treatment
Severe sensory neuropathy (Grade 3 or 4)	First	75 mg/M^2	4.5 mg•min/mL
	Second	50 mg/M^2	3 mg•min/mL
	Third	Discontinue treatment	Discontinue treatment

- Dose-level reductions for patients with adenocarcinoma of the pancreas are outlined in the following chart.

Abraxane Dose-Level Reductions for Patients With Adenocarcinoma of the Pancreas

Dose Level	Abraxane (mg/M^2)	Gemcitabine (mg/M^2)
Full dose	125 mg/M^2	1,000 mg/M^2
1st dose reduction	100 mg/M^2	800 mg/M^2
2nd dose reduction	75 mg/M^2	600 mg/M^2
If additional dose reduction required	Discontinue	Discontinue

- Dose modifications for neutropenia and/or thrombocytopenia for patients with adenocarcinoma of the pancreas are provided in the following chart.

Dose Recommendations and Modifications for Neutropenia and/or Thrombocytopenia for Patients With Adenocarcinoma of the Pancreas				
Cycle Day	**ANC (cells/mm^3)**		**Platelet Count (cells/mm^3)**	**Abraxane/Gemcitabine**
Day 1	<1,500	or	<100,000	Delay doses until recovery
Day 8	500 to <1,000	or	50,000 to <75,000	Reduce 1 dose level
	<500	or	<50,000	Withhold doses
Day 15: If Day 8 doses were reduced or given without modification:				
	500 to <1,000	or	50,000 to <75,000	Reduce 1 dose level from Day 8
	<500	or	<50,000	Withhold doses
Day 15: If Day 8 doses were withheld:				
	≥1,000	or	≥75,000	Reduce 1 dose level from Day 1
	500 to <1,000	or	50,000 to <75,000	Reduce 2 dose levels from Day 1
	<500	or	<50,000	Withhold doses

ANC, Absolute neutrophil count.

- Dose modifications for other adverse reactions for patients with adenocarcinoma of the pancreas are provided in the following chart.

Dose Modifications for Other Adverse Reactions for Patients With Adenocarcinoma of the Pancreas		
Adverse Drug Reaction	**Abraxane**	**Gemcitabine**
Febrile Neutropenia: Grade 3 or 4	Withhold until fever resolves and ANC ≥1,500; resume at next lower dose level	
Peripheral Neuropathy: Grade 3 or 4	Withhold until improves to ≤Grade 1; resume at next lower dose level	No dose reduction
Cutaneous Toxicity: Grade 2 or 3	Reduce to next lower dose level; discontinue treatment if toxicity persists	
Gastrointestinal Toxicity: Grade 3 mucositis or diarrhea	Withhold until improves to ≤Grade 1; resume at next lower dose level	

DILUTION

Specific techniques required; see Precautions.

Conventional Paclitaxel

Must be diluted and given as an infusion. May leach the toxic plasticizer DEHP from PVC infusion bags or sets; prepare and store in bottles (glass, polypropylene) or plastic bags (polypropylene, polyolefin) and administer through polyethylene-lined administration sets. **Compatible** with NS, D5W, D5NS, or D5R. Final concentration of 0.3 to 1.2 mg/mL required. For a 135 mg/M^2 dose, a large adult (body surface about 2

M^2) will receive 270 mg (45 mL of paclitaxel at 6 mg/mL). Will require dilution in an additional 180 mL to make a 1.2 mg/mL concentration or in an additional 855 mL to make a 0.3 mg/mL concentration. Solution may appear hazy. Do not use a chemo-dispensing pin; can cause the stopper to collapse and result in loss of sterility.

Abraxane

Available in single-use vials, each containing 100 mg (5 mg/mL after reconstitution with 20 mL of NS). Calculate the exact number of vials needed to achieve the total dosing volume of suspension required.

Total # of vials required = Total dose (mg) ÷ 100 mg

Dosing volume (mL) = Total dose (mg) ÷ 5 (mg/mL)

For example, a MBC patient with a body surface area (BSA) of 1.73 M^2 would need a dose of 449.8 mg of Abraxane. 449.8 mg divided by 100 mg equals 4.498 vials, so 5 vials of Abraxane would be needed. 449.8 mg divided by 5 (mg/mL) equals a dosing volume of 90 mL of reconstituted solution.

Reconstitute each 100-mg vial with 20 mL of NS. A specific process is required to avoid foaming or clumping. Over a minimum of 1 minute, slowly inject the NS, directing it to the inside wall of the vial. Do not allow the NS to flow directly onto the lyophilized cake (will cause foaming). Allow each vial to sit for a minimum of 5 minutes while the NS wets the cake. Gently swirl and/or invert each vial slowly for at least 2 minutes until complete dissolution. Avoid generation of foam. If foaming or clumping occurs, allow solution to stand for at least 15 minutes until foam subsides. Solution should be milky and homogenous without visible particulates. If particulates are visible, gently invert to ensure complete resuspension before use.

Withdraw the calculated volume and inject into an empty sterile polyvinyl chloride (PVC) container or a PVC or non–PVC-type infusion bag (a total dosing volume of 90 mL in the previous example). The use of medical devices containing silicone oil as a lubricant (i.e., syringes and IV bags) to reconstitute and administer Abraxane may result in the formation of proteinaceous strands. Discard suspension if proteinaceous strands, particulate matter, or discoloration are observed.

Filters:

Conventional paclitaxel:

Use of an in-line filter not greater than 0.22 microns required for administration.

Storage:

Conventional paclitaxel: May be stored at CRT or refrigerated before dilution (may appear precipitated under refrigeration; will redissolve at room temperature). Diluted for infusion, it is stable at room temperature for up to 27 hours. ***Abraxane:*** Store vials in original package at 20° to 25° C (68° to 77° F). Protect from light. Refrigeration or freezing does not affect stability of the product. Immediate use of reconstituted solution is preferred, but reconstituted vial may be refrigerated at 2° to 8° C (36° to 46° F) for a maximum of 24 hours if necessary. If refrigeration required, return to original carton to protect from light. Ensure complete resuspension after removing from refrigerator by gently inverting. Discard unused portions of the vial. Reconstituted solution in an infusion bag should be used immediately; however, it may be refrigerated and protected from bright light for a maximum of 24 hours. The total combined refrigerated storage time of reconstituted Abraxane in the vial and in the infusion bag is 24 hours. This may be followed by storage in the infusion bag at ambient temperature and lighting conditions for a maximum of 4 hours.

COMPATIBILITY

Conventional Paclitaxel

Leaches out plasticizers; see Dilution.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

Abraxane

Manufacturer states, "Use of specialized DEHP-free solution containers or administration sets is not necessary." The use of medical devices containing silicone oil as a lubricant (i.e., syringes and IV bags) to reconstitute and administer Abraxane may result in the formation of proteinaceous strands. Additional specific information not available.

RATE OF ADMINISTRATION

Conventional Paclitaxel

A single dose properly diluted must be equally distributed over 3 hours or as indicated in Usual Dose. Use of an in-line filter not greater than 0.22 microns required. Use a metriset (60 gtt/mL) or an infusion pump appropriate to control flow. Rate extended to 24 hours in some regimens.

Abraxane

A single dose properly reconstituted and equally distributed over 30 minutes.

ACTIONS

All Formulations

An antineoplastic. A novel antimicrotubule inhibitor. Paclitaxel derived from the bark of Pacific yew has now been replaced by paclitaxel produced semi-synthetically from a renewable source (needles and twigs of the Himalayan yew). Both are chemically identical. Through specific processes it stabilizes microtubules by preventing depolymerization. This action inhibits the normal dynamic reorganization of the microtubule network essential for vital interphase and mitotic cellular functions. Also induces abnormal bundles of microtubules throughout the cell cycle and multiple asters of microtubules during mitosis. Distribution and/or tissue binding is extensive.

Evidence suggests metabolism in the liver via the cytochrome P_{450} isoenzyme system (CYP2C8 and CYP3A4). Terminal half-life ranges from 13.1 to 27 hours. Excreted primarily as metabolites in feces and, to a lesser extent, in urine.

Conventional Paclitaxel

More active in patients who have not received previous chemotherapy.

Abraxane

Consists of albumin-bound paclitaxel nanoparticles. Highly bound to serum proteins; metabolized in the liver, primarily by CYP2C8 and, to a lesser extent, by CYP3A4. Terminal half-life ranges from 13 to 27 hours. Minimal excretion in urine and feces.

INDICATIONS AND USES

Conventional Paclitaxel

First-line and subsequent therapy for the treatment of advanced carcinoma of the ovary. ■ First-line treatment for ovarian cancer in combination with cisplatin. ■ Adjuvant treatment of node-positive breast cancer administered sequentially to standard doxorubicin-containing combination chemotherapy. Most effective in estrogen- and progesterone-receptor–negative tumors. ■ Metastatic breast cancer refractory to initial chemotherapy or for a relapse within 6 months. ■ First-line treatment, in combination with cisplatin, for non–small-cell lung cancer in patients who are not candidates for potentially curative surgery or radiation therapy. ■ Second-line treatment of AIDS-related Kaposi's sarcoma.

Abraxane

Treatment of breast cancer after failure of combination chemotherapy for metastatic disease or relapse within 6 months of adjuvant chemotherapy. Prior therapy should have included an anthracycline unless clinically contraindicated. ■ First-line treatment of locally advanced or metastatic non–small-cell lung cancer (NSCLC) (in combination with carboplatin) in patients who are not candidates for curative surgery or radiation therapy. ■ First-line treatment of patients with metastatic adenocarcinoma of the pancreas, in combination with gemcitabine.

Unlabeled uses:

Conventional paclitaxel: Advanced head and neck cancer. ■ Cancers of the bladder and cervix. ■ Small-cell lung cancer. ■ In combination with other agents for treatment of metastatic breast cancer. ■ Relapsed or refractory testicular cancer and testicular germ cell tumors. ■ Treatment of (unknown primary) adenocarcinoma. ***Abraxane:*** Recurrent ovarian, fallopian, and primary peritoneal cancers.

CONTRAINDICATIONS

Conventional Paclitaxel

Baseline neutropenia less than 1,500 cells/mm^3 in patients with solid tumors or baseline neutropenia less than 1,000 cells/mm^3 in patients with AIDS-related Kaposi's sarcoma. History of prior severe hypersensitivity reactions to paclitaxel or other drugs formulated in polyoxyethylated castor oil (Cremophor EL [e.g., cyclosporine, teniposide]).

Abraxane

Baseline neutrophil count less than 1,500 cells/mm^3. ■ Patients who experience a severe hypersensitivity reaction to Abraxane should not be rechallenged with the drug.

PRECAUTIONS

All Formulations

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Usually administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency.

Conventional Paclitaxel

Use caution in patients with cardiac conduction abnormalities, CHF, and MI within previous 6 months. ■ Bradycardia, hypertension, and hypotension have been observed but rarely required treatment. Occasionally the infusion must be interrupted or discontinued because of initial or recurrent hypertension; see Monitor. ■ Pre-existing neuropathies resulting from prior therapies are not a contraindication for paclitaxel therapy. ■ Various studies show that incidence and severity of neurotoxicity and hematologic toxicity increase with dose, especially above 190 mg/M^2. ■ Use with caution in patients with a total bilirubin greater than 2 times the ULN. May be at increased risk of toxicity, especially profound myelosuppression; see Dose Adjustments. ■ See Drug/Lab Interactions.

Abraxane

Do not substitute for or with other paclitaxel formulations. ■ Use of gloves recommended. Wash skin immediately if contact occurs. Flush mucous membranes thoroughly with water if contact occurs. Topical exposure may result in tingling, burning, and redness. ■ Premedication to prevent hypersensitivity reactions is not required but may be needed in patients who have had a prior hypersensitivity reaction to Abraxane. Reports of severe and sometimes fatal hypersensitivity reactions have occurred; see Contraindications; do not rechallenge patients who have had a severe reaction. ■ Neutropenia is dose dependent and is a dose-limiting toxicity. Do not administer Abraxane to patients with a baseline absolute neutrophil count (ANC) of less than 1,500 cells/mm^3; see Dose Adjustments. ■ Sensory neuropathy is dose dependent and schedule dependent and occurs frequently; see Dose Adjustments. ■ Sepsis occurred in 5% of patients, with or without neutropenia, who received Abraxane in combination with gemcitabine. Biliary obstruction or the presence of a biliary stent were risk factors for severe or fatal sepsis. ■ Pneumonitis, including some cases that were fatal, has been reported in patients receiving Abraxane in combination with gemcitabine; see Antidote. ■ Has not been studied in patients with severe renal dysfunction or end-stage renal disease. ■ Use with caution in patients with hepatic impairment. May be at increased risk for toxicity, particularly myelosuppression; see Dose Adjustments. ■ Derived from human albumin; may carry a risk of transmission of viral disease or Creutzfeldt-Jakob disease; risk considered extremely remote. ■ Has not been studied in patients who have had a hypersensitivity reaction to conventional paclitaxel.

Monitor:

All Formulations:

Neutropenia is dose dependent and is the dose-limiting toxicity. Obtain baseline CBC with differential and platelet count. Monitor frequently during therapy and before each dose. ■ Monitor injection site carefully; avoid extravasation. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Conventional Paclitaxel:

Neutrophil nadir occurs around Day 11; see Dose Adjustments. ■ Monitor VS frequently, particularly during the first hour of the infusion. ■ Consider obtaining a baseline ECG; arrhythmias have occurred. Continuous cardiac monitoring required for all patients with an abnormal baseline ECG or for those who experienced conduction arrhythmias during administration of a previous dose. ■ Monitoring of cardiac function is recommended when paclitaxel is used in combination with doxorubicin; see doxorubicin monograph. ■ Anaphylaxis and severe hypersensitivity reactions characterized by dyspnea, hypotension requiring treatment, angioedema, and generalized urticaria have been reported. Fatal reactions have occurred despite premedication. ■ Most severe hypersensitivity reactions occur in the first hour; chest pain, dyspnea, flushing, and tachycardia were the most frequent initial symptoms; abdominal pain, diaphoresis, extremity pain, and hypertension also occurred. Monitor all vital signs, including BP, continuously for the first 30 minutes of the infusion and at frequent intervals after that. Incidence seems to decrease with subsequent doses. ■ Treatment can often be continued in patients with mild hypersensitivity reactions if proper premedication is given. ■ Monitor injection site carefully; avoid extravasation. Incidence of inflammation increased with 24-hour infusions. Injection site reactions may occur during administration or be delayed by 7 to 10 days. Recurrence of skin reactions at a site of previous extravasation following administration of paclitaxel ("recall") has been reported.

Abraxane:

Limited infusion time (30 minutes) reduces the likelihood of infusion-related reactions; however, they have been reported; monitor for S/S. ■ Monitor for S/S of hypersensitivity reactions. ■ Monitor for S/S of sensory neuropathy. ■ Monitor for

S/S of pneumonitis. ■ Based on patient history, a baseline ECG may be indicated. ■ See Precautions and Dose Adjustments.

Patient Education:

All Formulations:

Effective birth control recommended for males and females; see Maternal/Child. ■ Review of monitoring requirements and adverse events before therapy imperative. ■ Report any unusual or unexpected symptoms, side effects, pain or burning at injection site, S/S of a hypersensitivity reaction (e.g., bronchospasm, difficulty breathing, rash, urticaria), signs of infection (e.g., chills, fever, night sweats), signs of sensory neuropathy (e.g., numbness, tingling, or burning in hands and/or feet), signs of pneumonitis (e.g., dry, persistent cough or shortness of breath), or signs of bleeding (e.g., bruising, tarry stools, blood in urine, pinpoint red spots on skin) as soon as possible. ■ Avoid tasks that require mental alertness (e.g., driving, operating machinery) until the effect of the medication is known. Side effects such as fatigue, lethargy, and malaise may affect the ability to perform these tasks. ■ See Appendix D, p. 1311. ■ Obtain name and telephone number of a contact person for emergencies, questions, or problems. ■ Seek resources for counseling or supportive therapy. ■ Manufacturer provides a patient information booklet.

Maternal/Child:

All Formulations:

Category D: females should avoid pregnancy, and males should avoid fathering a child. May cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Conventional Paclitaxel:

CNS toxicity (rarely associated with death) was reported in one pediatric trial using high-dose paclitaxel. Use of antihistamines and the ethanol contained in the paclitaxel may have contributed to toxicity noted.

Elderly:

All Formulations:

Studies suggest response is similar to that seen in younger patients.

Conventional Paclitaxel:

Incidence of side effects, including myelosuppression, neuropathy, and cardiovascular events, may be increased in the elderly.

Abraxane:

Increased incidence of dehydration, diarrhea, epistaxis, fatigue, and peripheral edema was seen in elderly patients receiving Abraxane as monotherapy for MBC. Incidence of myelosuppression, neuropathy, and arthralgia was more common in patients receiving

Abraxane and carboplatin for treatment of NSCLC. Incidence of decreased appetite, dehydration, diarrhea, and epistaxis was more common in patients receiving Abraxane and gemcitabine for treatment of adenocarcinoma of the pancreas.

DRUG/LAB INTERACTIONS

All Formulations

Do not administer **chloroquine or live virus vaccines** to patients receiving antineoplastic agents.

Conventional Paclitaxel

Formal drug interaction studies have not been conducted. To reduce potential for profound myelosuppression when using paclitaxel and cisplatin concurrently, give paclitaxel first, then cisplatin. ■ Neurotoxicity and symptomatic motor dysfunction occurring with higher doses (greater than 250 mg/M^2) may be potentiated by **cisplatin and filgrastim** (G-CSF). ■ May cause additive effects with **bone marrow–suppressing agents, radiation therapy, or agents that cause blood dyscrasias** (e.g., amphotericin B, antithyroid agents [methimazole], azathioprine, chloramphenicol, ganciclovir, interferon, plicamycin, zidovudine). Reduced doses may be required. ■ May increase levels of **doxorubicin** and its active metabolite when drugs are used in combination. ■ Metabolized by **cytochrome P_{450} isoenzymes CYP3A4 and CYP2C8.** Use caution when administered concomitantly with known **substrates** (e.g., buspirone, eletriptan, felodipine, lovastatin, midazolam, sildenafil, simvastatin, and triazolam), **inhibitors** (e.g., atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir), **and inducers** (e.g., rifampin and carbamazepine) **of CYP3A4.** ■ **Other medications that are substrates and/or inducers of CYP3A4** may alter the metabolism of paclitaxel but have not been evaluated in clinical trials. ■ Use caution when administered concomitantly with known **substrates** (e.g., repaglinide), **inhibitors** (e.g., gemfibrozil), **and inducers** (e.g., rifampin) **of CYP2C8.**

Abraxane

Drug interaction studies have not been conducted. See All Formulations above. ■ Use caution when administering with medicines **known to inhibit or induce CYP2C8 or CYP3A4.** Drugs that may inhibit these enzymes include ketoconazole and other imidazole antifungals, erythromycin, fluoxetine, gemfibrozil, cimetidine, ritonavir, saquinavir, indinavir, and nelfinavir. Drugs that may induce these enzymes include rifampin, carbamazepine, phenobarbital, phenytoin, efavirenz, and nevirapine.

SIDE EFFECTS

Conventional Paclitaxel

Dose dependent and generally reversible, but may be fatal. All patients were premedicated to prevent hypersensitivity reactions. Abnormal ECG, alopecia, arthralgia/myalgia, asthenia, autonomic neuropathy resulting in paralytic ileus, bleeding, bone marrow suppression (anemia, leukopenia, neutropenia, thrombocytopenia), bradycardia, CHF (including cardiac dysfunction and reduction in left ventricular ejection fraction or ventricular failure [more common in patients receiving combination therapy with anthracyclines]), diarrhea, elevated alkaline phosphatase, elevated AST, elevated bilirubin, febrile neutropenia, fever, fluid retention and edema, hypersensitivity reactions (moderate [e.g., dyspnea, flushing, hypotension, rash, tachycardia]; severe [e.g., chest pain, dyspnea requiring bronchodilators, hypotension requiring treatment, generalized urticaria]), hypertension, hypotension, infections including opportunistic infections (chills, fever, night sweats), injection site reactions (cellulitis, fibrosis, induration, necrosis, phlebitis, skin exfoliation), mucositis, nausea and vomiting, numbness, optic nerve and/or visual disturbances, peripheral neuropathy, respiratory reactions (interstitial pneumonia, lung fibrosis, pleural effusions, pulmonary embolism, respiratory failure), Stevens-Johnson syndrome, toxic epidermal necrolysis, and visual disturbances. A grand mal seizure occurred in one patient. Other side effects (e.g., cardiac arrest, cardiac ischemia/infarction, CVA, hepatic necrosis, and hepatic encephalopathy leading to death; intestinal obstruction; intestinal perforation; ischemic colitis; pancreatitis; thrombosis/embolism) have been reported rarely. A higher incidence of elevated liver function tests and renal toxicity is seen in Kaposi's sarcoma patients.

Post-Marketing:

Diffuse edema, thickening, and sclerosing of the skin; exacerbation of S/S of scleroderma; ototoxicity.

Abraxane

Single-agent use in patients with MBC:

Abnormal ECG, alopecia, anemia, diarrhea, elevation of alkaline phosphate and AST, fatigue/asthenia, infections (oral candidiasis, pneumonia, and respiratory tract), myalgia/arthralgia, nausea, neutropenia, and sensory neuropathy are most common.

Combination use in patients with NSCLC:

Alopecia, anemia, fatigue, nausea, neutropenia, peripheral neuropathy, and thrombocytopenia are most common. The most serious side effects reported are anemia and pneumonia. The most common side effects that result in dose reduction, the withholding of a dose, or a delay in dosing are anemia, neutropenia, and thrombocytopenia. Neutropenia, peripheral neuropathy, and thrombocytopenia sometimes resulted in permanent discontinuation of Abraxane.

Combination use in patients with adenocarcinoma of the pancreas:

Alopecia, decreased appetite, dehydration, diarrhea, fatigue, fever, nausea, neutropenia, peripheral edema, peripheral neuropathy, rash, and vomiting. The most common serious side effects are dehydration, fever, pneumonia, and vomiting. The most common side effects that result in dose reduction or delay in dosing are anemia, diarrhea, fatigue, neutropenia, peripheral neuropathy, and thrombocytopenia. The most common side effects resulting in permanent discontinuation are fatigue, peripheral neuropathy, and thrombocytopenia.

All diagnoses with Abraxane:

Hypersensitivity reactions have occurred but are not usually severe; premedication is not indicated. Other side effects have been reported and include bradycardia, cardiovascular events (e.g., cardiac ischemia/infarction, SVT), dehydration, extravasation, fever, hypotension, pancytopenia, pneumonitis, pneumothorax, Stevens-Johnson syndrome, toxic epidermal necrolysis, and many others. Frequency of sensory neuropathy may increase with cumulative dose.

Post-Marketing:

Many of these side effects occur with paclitaxel and Abraxane and include CHF, left ventricular dysfunction, and atrioventricular block; cranial nerve palsies; hepatic necrosis and hepatic encephalopathy; injection site reactions; interstitial pneumonia; intestinal obstruction or perforation; ischemic colitis; pancreatitis; paralytic ileus; pneumonitis; pulmonary embolism; visual disorders (reduced visual acuity); vocal cord paresis. Rare reports of severe hypersensitivity reactions have occurred with Abraxane.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. Most hypersensitivity reactions will subside with temporary discontinuation of paclitaxel, and incidence seems to decrease with subsequent doses. Moderate reactions such as dyspnea, flushing, hypotension, skin reactions, or tachycardia do not usually require interruption of treatment. Severe reactions may require epinephrine, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., dexamethasone), or bronchodilators (e.g., albuterol, theophylline). Most severe reactions should not be rechallenged, but some patients tolerated subsequent doses of **conventional paclitaxel;** see Contraindications. Neutropenia can be profound, and the nadir usually occurs about Day 11 with **conventional paclitaxel.** Recovery is generally rapid and spontaneous but may be treated with filgrastim or pegfilgrastim. Severe thrombocytopenia (nadir Day 8 or 9 with **conventional paclitaxel**) may require platelet transfusions. Severe anemia (less than 8 Gm/dL) may require packed cell transfusions. Hypotension and bradycardia do not usually occur at the same time except in hypersensitivity. Treat only if symptomatic. Some arrhythmias (e.g., nonspecific repolarization abnormalities, sinus tachycardia, and PVCs) are common and may not require intervention. Promptly treat any serious or symptomatic arrhythmia (e.g., conduction abnormalities, ventricular tachycardia), and monitor continuously during subsequent doses. Neurologic symptoms tend to worsen with each course; see Dose Adjustments. Usually improve within several months. Severe peripheral neuropathies or seizure may necessitate discontinuation of paclitaxel. Permanently discontinue treatment with **Abraxane** and gemcitabine if pneumonitis develops. There is no specific antidote for overdose. Supportive therapy will help sustain the patient in toxicity. Resuscitate if indicated.

PALIFERMIN

(**PAL**-lih-fur-min)
Kepivance, KGF
Keratinocyte growth factor
pH 6.5

USUAL DOSE

Administered as an IV bolus injection for 3 consecutive days before and 3 consecutive days after myelotoxic therapy (a total of 6 doses). Do not administer within 24 hours before, during infusion of, or within 24 hours after administration of myelotoxic chemotherapy. Has resulted in increased severity and duration of oral mucositis. Myelotoxic therapy is high-dose chemotherapy, with or without radiation, that is destructive to bone marrow or any of its components. Followed by bone marrow transplant/hematopoietic stem cell support.

Pre-myelotoxic therapy (first 3 doses):

Administer 60 mcg/kg/day for 3 consecutive days before beginning myelotoxic therapy, with the third dose 24 to 48 hours before myelotoxic therapy.

Post-myelotoxic therapy (last 3 doses):

Administer 60 mcg/kg/day for 3 consecutive days after myelotoxic therapy is complete; the first of these doses should be administered after, but on the same day of, hematopoietic stem cell infusion and at least 7 days after the most recent administration of palifermin. See Precautions.

DOSE ADJUSTMENTS

None indicated. Gender-related differences were not observed. ■ No dose adjustment is recommended in impaired renal function. ■ Pharmacokinetic studies have not been performed for pediatric patients or for patients with hepatic insufficiency.

DILUTION

Available as a lyophilized powder in a 6.25-mg single-dose vial. Reconstitute by slowly injecting 1.2 mL SWFI into vial. Final concentration is 5 mg/mL. Swirl contents gently. ***Do not shake.*** Dissolution should take less than 3 minutes. Solution is clear and colorless. Do not use if particulates are present or if solution is discolored.

Filters:

Manufacturer states, “Do not filter the reconstituted solution during preparation or administration.”

Storage:

Keep vials in carton until use. Store at 2° to 8° C (36° to 46° F). Protect from light. Do not use beyond expiration date on vial. Reconstituted product should be used immediately but can be stored up to 24 hours if refrigerated and stored in its carton. Do not freeze. Before administration, allow palifermin to reach room temperature for a maximum of 1 hour protected from light. Discard any unused product.

COMPATIBILITY

Manufacturer states, “If heparin is used to maintain an IV line, saline should be used to flush the line before and after administration since palifermin has been shown to bind to heparin in vitro.” Additional **compatibility** information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose administered as an IV bolus injection. If heparin is used to maintain an IV line, flush the line with NS before and after administration.

ACTIONS

Human keratinocyte growth factor (KGF) produced by recombinant DNA technology. Binding of KGF to its receptor results in proliferation, differentiation, and migration of epithelial cells. KGF receptors are present on the epithelial cells in many tissues, including the tongue, buccal mucosa, esophagus, stomach, intestine, salivary gland, lung, liver, pancreas, kidney, bladder, mammary gland, skin (hair follicles and sebaceous gland), and the lens of the eye. The KGF receptor is not present on the cells of the hematopoietic lineage. KGF stimulates the growth of cells in tissues such as the skin and the epithelial layer of the mouth, stomach, and colon. Protects the epithelial cells that line the mouth and GI tract from the damage caused by chemotherapy and radiation and stimulates the growth and development of new epithelial cells. Average half-life is 4.5 hours (range: 3.3 to 5.7 hours).

INDICATIONS AND USES

To decrease the incidence and duration of severe oral mucositis in patients with hematologic malignancies who are receiving myelotoxic therapy in the setting of autologous hematopoietic stem cell support. Indicated as supportive care for preparative regimens predicted to result in equal to or greater than WHO Grade 3 mucositis in the majority of patients.

Limitations of use:

Safety and efficacy for use in patients with nonhematologic malignancies not established; see Precautions. Palifermin was not effective in decreasing the incidence of severe mucositis in patients with hematologic malignancies receiving myelotoxic therapy in the setting of allogeneic hematopoietic stem cell support. ■ Not recommended for use with melphalan 200 mg/M^2 as a conditioning regimen.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Safety and efficacy have not been established in patients with nonhematologic malignancies. Effect of palifermin on stimulation of KGF receptor–expressing, nonhematopoietic tumors in patients is not known. Has been shown to enhance the growth of human epithelial tumor cell lines in vitro.

Monitor:

Monitor improvement in symptoms of oral mucositis. ■ Monitor for the appearance of mucocutaneous adverse effects (e.g., edema, erythema, oral/perioral dysesthesia [impairment of sensitivity to touch], rash, taste alteration, tongue discoloration, tongue thickening).

Patient Education:

Review possible side effects. ■ Promptly report side effects (e.g., edema, impairment of sensitivity to touch [especially around the mouth], rash, taste alteration, tongue discoloration, tongue thickening). ■ Inform patient of the evidence of tumor growth and stimulation in cell cultures and animal models of nonhematopoietic human tumors and that safety and efficacy have not been established in patients with nonhematologic malignancies.

Maternal/Child:

Category C: potential benefit to mother must justify potential risk to fetus. ■ Discontinue breast-feeding. ■ Information on dosing and safety in pediatric patients is limited. However, use in pediatric patients ages 1 to 16 years is supported by evidence from well-controlled studies in adults and from a Phase 1 study that included 27 pediatric patients with acute leukemia undergoing hematopoietic stem cell transplant. Adverse events were similar to those reported for adults, and age did not affect the pharmacokinetics of palifermin.

Elderly:

Clinical studies did not include sufficient numbers of subjects 65 years of age and older to determine whether they respond differently than do younger subjects. No dose adjustment is recommended.

DRUG/LAB INTERACTIONS

Formal studies have not been conducted. ■ Interacts with **unfractionated as well as low-molecular-weight heparins** (e.g., enoxaparin). When coadministered, there was no significant effect of palifermin on heparin activity with respect to aPPT. However, coadministration resulted in an increased palifermin AUC and a decreased palifermin clearance, volume of distribution, and half-life. Despite the changes in palifermin pharmacokinetics, coadministration did not have any noticeable effect on the pharmacodynamics of either drug. If heparin is used to maintain an IV line, NS should be used to flush the line before and after palifermin administration. ■ Do not administer within 24 hours before, during infusion of, or within 24 hours after administration of **myelotoxic chemotherapy.** Has resulted in increased severity and duration of oral mucositis.

SIDE EFFECTS

The most common side effects are elevated serum amylase, fever, and skin toxicities (edema, erythema, pruritus, skin rash). Other commonly reported reactions include arthralgia, dysesthesia, elevated serum lipase, oral toxicities (alteration in taste, dysesthesia, tongue discoloration and thickening), pain, and paresthesia. The most common serious adverse reaction was skin rash. Has the potential for immunogenicity, but the clinical significance is unknown.

Post-Marketing:

Cataracts, palmar-plantar erythrodysesthesia syndrome (dysesthesia, edema on the palms and soles, erythema), and vaginal edema and erythema.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically.

PALONOSETRON

(**pal**-oh-**NOH**-seh-tron)
Aloxi
Antiemetic (5-HT$_3$ receptor antagonist)
pH 4.5 to 5.5

USUAL DOSE

Adults:

0.25 mg as a single dose; infuse over 30 seconds starting 30 minutes before start of chemotherapy.

Pediatric patients (1 month to less than 17 years of age):

20 mcg/kg/dose, with a maximum of 1.5 mg as a single dose; infuse over 15 minutes starting 30 minutes before start of chemotherapy.

Postoperative nausea and vomiting in adults:

A single dose of 0.075 mg immediately before induction of anesthesia.

DOSE ADJUSTMENTS

No dose adjustment required based on age or race or in patients with any degree of renal or hepatic impairment.

DILUTION

Available in 0.25 mg/5 mL and 0.075 mg/1.5 mL single-use vials. May be given undiluted.

Filters:

No data available from manufacturer.

Storage:

Before use, store at CRT. Protect from freezing and light.

COMPATIBILITY

Manufacturer states, “Should not be mixed with other drugs. Flush the infusion line with NS before and after administration.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Flush the infusion line with NS before and after administration.

Chemotherapy-induced nausea and vomiting in adults and pediatric patients:

See Usual Dose.

Postoperative nausea and vomiting in adults:

A single dose as an IV injection equally distributed over 10 seconds.

ACTIONS

A long-acting (up to 120 hours [5 days]) antinauseant and antiemetic agent. A selective antagonist of specific serotonin (5-HT_3) receptors. Has a strong binding affinity for this receptor and little or no affinity for other receptors. Chemotherapeutic agents such as cisplatin increase the release of serotonin from specific cells in the GI tract, causing emesis. Postoperative nausea and vomiting are also triggered by the release of serotonin. By antagonizing serotonin receptors both on the vagus nerve in the periphery and centrally in the chemoreceptor trigger zone, the incidence and severity of chemotherapy-induced nausea and vomiting and postoperative nausea and vomiting are decreased. 62% bound to plasma protein. Partially metabolized by multiple CYP enzymes; however, palonosetron is not an inhibitor or an inducer of CYP enzyme activity. Eliminated slowly from the body through both metabolic pathways and renal excretion. Has a prolonged half-life of approximately 40 hours. 80% of a single dose was recovered in urine within 144 hours.

INDICATIONS AND USES

In pediatric patients 1 month to less than 17 years of age, prevention of acute nausea and vomiting associated with initial and repeat courses of *emetogenic* cancer chemotherapy, including *highly emetogenic* cancer chemotherapy. ■ In adults, prevention of acute and delayed nausea and vomiting associated with initial and repeat courses of *moderately emetogenic* cancer chemotherapy and prevention of acute nausea and vomiting associated with initial and repeat courses of *highly emetogenic* cancer chemotherapy. Studies identified cisplatin in doses equal to or greater than 70 mg/M^2 and cyclophosphamide (Cytoxan) in doses equal to or greater than 1,100 mg/M^2 as *highly emetogenic*. Studies identified cisplatin in doses equal to or less than 50 mg/M^2, cyclophosphamide in doses less than 1,100 mg/M^2, doxorubicin (Adriamycin) in doses greater than 25 mg/M^2, methotrexate in doses greater than 250 mg/M^2, and carboplatin, epirubicin (Ellence), and irinotecan (Camptosar) in standard doses as *moderately emetogenic.* ■ Prevention of postoperative nausea and vomiting (PONV) in adults for up to 24 hours following surgery. Efficacy beyond 24 hours has not been demonstrated.

CONTRAINDICATIONS

Known hypersensitivity to palonosetron or any of its components. ■ See Precautions.

PRECAUTIONS

Hypersensitivity reactions, including anaphylaxis, have been reported with or without known hypersensitivity to other 5-HT$_3$ receptor antagonists. Cross-sensitivity may occur with other selective 5-HT$_3$ receptor antagonists. ■ Serotonin syndrome has been reported with 5-HT$_3$ receptor antagonists. Most reports were associated with concomitant use of serotonergic drugs (e.g., selective serotonin reuptake inhibitors, serotonin and norepinephrine reuptake inhibitors, monoamine oxidase inhibitors, mirtazapine, fentanyl, lithium, and tramadol). Some cases were fatal. ■ Routine prophylaxis is not recommended for patients in whom there is little expectation of PONV. However, for patients in whom nausea and vomiting must be avoided during the postoperative period, prophylaxis is recommended even when the incidence of PONV is low. ■ Palonosetron does not appear to have any effect on ECG intervals, including QTc duration.

Monitor:

Observe closely. Monitor VS. ■ Monitor for serotonin syndrome, especially when palonosetron is used concurrently with other serotonergic drugs. Symptoms associated with serotonin syndrome may include the following combination of S/S: mental status changes (e.g., agitation, coma, delirium, hallucinations), autonomic instability (e.g., diaphoresis, dizziness, flushing, hyperthermia, labile blood pressure, tachycardia), neuromuscular symptoms (e.g., hyperreflexia, incoordination, myoclonus, rigidity, tremor), and seizures, with or without GI symptoms (e.g., diarrhea, nausea, vomiting). ■ Ambulate slowly to avoid orthostatic hypotension. ■ Stool softeners or laxatives may be required to prevent constipation.

Patient Education:

Request assistance with ambulation. ■ Used to prevent and/or treat both early and late N/V caused by chemotherapy. Report persistent N/V promptly. ■ Maintain adequate hydration. ■ Review prescription and nonprescription medications with health care provider. Drug interactions are possible, especially with diuretics or antiarrhythmics. ■ Review other medical conditions with health care provider. ■ Promptly report S/S of serotonin syndrome (e.g., altered mental status, autonomic instability, and neuromuscular symptoms); see Precautions.

Maternal/Child:

Category B: use during pregnancy only if clearly needed. ■ Safety for use during breast-feeding not established; effects unknown, but potential for tumorigenicity is a concern. Discontinue breast-feeding. ■ Safety and effectiveness have been established for use in pediatric patients 1 month to less than 17 years of age for the prevention of acute nausea and vomiting associated with initial and repeat courses of emetogenic cancer chemotherapy, including highly emetogenic chemotherapy. Pediatric patients require a higher palonosetron dose than adults to prevent chemotherapy-induced nausea and vomiting. However, the safety profile seen in pediatric patients is consistent with the established profile in adults. ■ Safety and effectiveness have not been established in pediatric patients for prevention of postoperative nausea and vomiting.

Elderly:

Safety and effectiveness similar to younger adults; however, greater sensitivity in some elderly cannot be ruled out. No dose adjustment or special monitoring required.

DRUG/LAB INTERACTIONS

Eliminated through both renal excretion and metabolic pathways. Does not induce or inhibit the cytochrome P_{450} drug metabolizing system; potential for clinically significant drug interactions is considered to be low. ■ Serotonin syndrome (including altered mental status, autonomic instability, and neuromuscular symptoms) has been reported following the concomitant use of 5-HT_3 receptor antagonists and other serotonergic drugs, including selective serotonin reuptake inhibitors (SSRIs) and serotonin and norepinephrine reuptake inhibitors (SNRIs). ■ See Precautions.

SIDE EFFECTS

Chemotherapy-induced nausea and vomiting in adults:

The most common side effects are headache and constipation. Other reported side effects include abdominal pain, diarrhea, dizziness, fatigue, and insomnia.

Chemotherapy-induced nausea and vomiting in pediatric patients:

Allergic dermatitis, dizziness, dyskinesia, headache, and infusion site pain.

Postoperative nausea and vomiting:

The most common side effects, occurring in at least 2% of patients, are bradycardia, constipation, headache, and QT prolongation. Several other side effects are reported in 1% or fewer of patients.

Overdose:

Doses more than 20 times the recommended dose did not cause significant problems. Collapse, convulsions, cyanosis, gasping, and pallor occurred in animal studies with rats and mice.

Post-Marketing:

Rare cases of hypersensitivity reactions, including anaphylaxis, anaphylactic shock, and injection site reactions (burning, induration, pain). Serotonin syndrome has been reported as a 5-HT_3 class reaction.

ANTIDOTE

Most side effects will be treated symptomatically. Keep physician informed. There is no specific antidote. If symptoms of serotonin syndrome occur, discontinue palonosetron and initiate supportive care. Has a large volume of distribution; dialysis not likely to be effective in overdose. Treat hypersensitivity reactions and resuscitate as indicated.

PAMIDRONATE DISODIUM

(pah-**MIH**-droh-nayt **DYE**-so-dee-um)
APD, Aredia
Bone resorption inhibitor
Antihypercalcemic (bisphosphonate)
pH 6 to 7.4

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies and prehydration required. See Precautions and Monitor.

Do not exceed a 90-mg dose.

Moderate hypercalcemia (corrected serum calcium of 12 to 13.5 mg/dL):

One dose of 60 to 90 mg as an infusion.

Severe hypercalcemia (corrected serum calcium greater than 13.5 mg/dL):

One dose of 90 mg as an infusion. Serum calcium levels should fall into the normal range (8.5 to 10.5 mg/100 mL, corrected for serum albumin).

Experience is limited, but retreatment with the same dose may be considered if hypercalcemia is not fully corrected or recurs; wait at least 7 days from completion of first infusion to allow full response. Always used in conjunction with adequate hydration and appropriate testing. See Precautions/Monitor.

Paget’s disease:

30 mg/day as an infusion for 3 consecutive days (total dose is 90 mg over 3 days). Selected patients have been retreated with the same dose when indicated. Experience limited. Prehydration required; see Precautions and Monitor.

Osteolytic bone lesions of multiple myeloma:

90 mg as an infusion once every 30 days. Optimal duration of therapy not known. Withhold dose if renal function has deteriorated; see Dose Adjustments, Precautions, and Monitor.

Osteolytic bone metastases of breast cancer:

90 mg as an infusion every 3 to 4 weeks. Optimum duration of therapy not known. Withhold dose if renal function has deteriorated; see Dose Adjustments, Precautions, and Monitor.

DOSE ADJUSTMENTS

Accumulation of pamidronate in renally impaired patients is not anticipated if dosed on a monthly schedule. No experience with creatinine above 5 mg/100 mL (1 dL) or in severe hepatic disease. ■ See Precautions and Elderly.

Osteolytic bone lesions of multiple myeloma and osteolytic bone metastases of breast cancer:

Withhold dose if renal function has deteriorated. Renal deterioration is defined as an increase of 0.5 mg/dL in patients with a *normal* baseline creatinine or an increase of 1 mg/dL in patients with *abnormal* baseline creatinine. One study suggests that treatment should not be resumed until SCr has returned to within 10% of baseline value.

DILUTION

Reconstitute each 30- or 90-mg vial with 10 mL SWFI. Dissolve completely (3 or 9 mg/mL).

Hypercalcemia of malignancy:

Further dilute a single dose in 1,000 mL NS, ½NS, or D5W. A minimum of 500 mL diluent may be used if absolutely necessary in patients with compromised cardiovascular status.

Paget’s disease:

Further dilute a single daily dose in 500 mL NS, ½NS, or D5W.

Osteolytic bone lesions of multiple myeloma:

Further dilute each 90-mg dose in 500 mL NS, ½NS, or D5W.

Osteolytic bone metastases of breast cancer:

Further dilute each 90-mg dose in 250 mL NS, ½NS, or D5W.

Storage:

Before reconstitution, store at CRT. After reconstitution, may be refrigerated for up to 24 hours. Stable after dilution for 24 hours at room temperature.

COMPATIBILITY

Should be given in a single intravenous solution and line separate from all other drugs, and do not mix with calcium-containing solutions (e.g., Ringer’s solutions).

RATE OF ADMINISTRATION

Use of a microdrip (60 gtt/mL) or an infusion pump recommended for even distribution. Do not exceed recommended rate of infusion. Duration should be no less than 2 hours. Too-rapid infusion rate may lead to overdose, elevated BUN and creatinine levels, and renal tubular necrosis. Rate recommendations vary considerably. They are based on specific clinical trials for each diagnosis. In some trials a rate of up to 1 mg/min has been used with caution.

Hypercalcemia of malignancy:

A 60-mg dose or 90-mg dose equally distributed over 2 to 24 hours. Longer infusion times (i.e., greater than 2 hours) may reduce the risk of renal toxicity, particularly in patients with pre-existing renal insufficiency.

Paget's disease:

A single dose over 4 hours.

Osteolytic bone lesions of multiple myeloma:

A single dose over 4 hours.

Osteolytic bone metastases of breast cancer:

A single dose over 2 hours.

ACTIONS

A bisphosphonate hypocalcemic agent. Reduces serum calcium concentrations by inhibiting bone resorption. Binds to preformed bone surfaces and may block bone mineral dissolution. May also inhibit osteoclast activity. Effectively inhibits accelerated bone resorption resulting from osteoclast hyperactivity induced by various tumors. Does not inhibit bone formation and mineralization. Some reduction in calcium levels seen in 24 to 48 hours, and maximum response in 4 to 7 days. Rapidly adsorbed by bone. Is not metabolized. Half-life is approximately 21 to 35 hours. Slowly excreted in urine.

INDICATIONS AND USES

Treatment of moderate to severe hypercalcemia of malignancy in patients with or without bone metastasis, in conjunction with adequate hydration. Symptoms of hypercalcemia may include anorexia, bone pain, confusion, constipation, dehydration, depression, fatigue, lethargy, muscle weakness, nausea and vomiting, and polyuria. Severe dehydration may lead to renal insufficiency. With high levels of serum calcium, cardiac manifestations (e.g., bradycardia, cardiac arrest, ventricular arrhythmias) and neurologic symptoms (e.g., coma, seizures, and death) may occur. ■ Treatment of Paget's disease. ■ Adjunct in treatment of osteolytic lesions of multiple myeloma and osteolytic bone metastases of breast cancer.

Unlabeled uses:

Prevention of bone loss associated with androgen deprivation therapy in prostate cancer.

CONTRAINDICATIONS

Hypersensitivity to pamidronate or other bisphosphonates (e.g., alendronate, risedronate, zoledronic acid).

PRECAUTIONS

Calcium is bound to albumin. Total serum calcium levels in patients who have hypercalcemia of malignancy may not reflect the severity of the hypocalcemia because concomitant hypoalbuminemia is commonly present. Measurement with ionized calcium levels is preferred. If unavailable, all calcium measurement should be corrected for albumin to establish a basis for treatment and evaluation of treatment. ■ Mild or asymptomatic hypercalcemia will be treated with conservative measures (e.g., saline hydration, with or without diuretics [after correcting hypovolemia]). Consider patient's cardiovascular status. Corticosteroids may be indicated if the underlying cancer is sensitive (e.g., hematologic cancers). ■ May be used adjunctively with chemotherapy, radiation, or surgery. ■ May cause renal toxicity. Deterioration in renal function progressing to renal failure has been reported and has occurred after the initial or a single dose of pamidronate. Patients with pre-existing renal impairment may be at increased risk for developing toxicity. Do not exceed dose of 90 mg. ■ Osteonecrosis of the jaw (ONJ) has been reported in patients receiving bisphosphonates. The majority of cases have been in cancer patients. Risk factors include cancer, concomitant therapy (e.g., chemotherapy, radiotherapy, corticosteroids), and comorbid conditions (e.g., anemia, coagulopathies, infection, pre-existing oral disease). Literature and case reports suggest a higher frequency of ONJ based on tumor type (breast cancer, multiple myeloma) and dental status (dental extraction, periodontal disease, local trauma, including poorly fitting dentures). Cancer patients should maintain good oral hygiene. Consider dental exam and appropriate preventive dentistry before beginning therapy with bisphosphonates. Avoid invasive dental procedures during bisphosphonate therapy. Dental surgery may exacerbate ONJ in patients who develop ONJ while on bisphosphonate therapy. ■ Severe and occasionally incapacitating bone, joint, and/or muscle pain has been reported rarely. Onset of symptoms varied from one day to several months after beginning treatment with pamidronate. In most cases, pain resolves when pamidronate is discontinued; however, in some patients symptoms resolved slowly or persisted. ■ Atypical subtrochanteric and diaphyseal femoral fractures have been reported. May occur after minimal or no trauma. Risk may be increased in patients receiving concurrent glucocorticoids (e.g., dexamethasone, prednisone). ■ May be at risk for anemia, leukopenia, or thrombocytopenia; see Monitor. ■ Patients with a history of thyroid surgery may have relative hypoparathyroidism that may predispose them to hypocalcemia with pamidronate. ***Osteolytic bone lesions of multiple myeloma and osteolytic bone metastases of breast cancer:*** Patients being treated for multiple myeloma and bone metastases should have the dose withheld if renal function has deteriorated; see Dose Adjustments. Use is not recommended in patients with severe renal impairment being treated for bone metastases. See Monitor and Dose Adjustments. Limited information available on use in multiple myeloma patients with a CrCl less than 30 mL/min. In clinical trials, patients with a SCr above 3 mg/dL were excluded. ■ In the absence of hypercalcemia, patients with ***multiple myeloma*** or ***Paget's disease of the bone*** or patients with ***predominantly lytic bone metastases*** who are at risk for calcium and vitamin D deficiency should be given oral calcium and vitamin D to reduce the risk of hypocalcemia.

Monitor:

Obtain baseline measurements of serum calcium (corrected for serum albumin), electrolytes, phosphate, magnesium, and creatinine and CBC with differential and hematocrit/hemoglobin. Monitor all closely as indicated by baseline results (may be daily). Serum phosphate levels will decrease and may require treatment. ■ Monitor renal function before each treatment; deterioration in renal function has been reported; see Precautions. ■ Monitor serum alkaline phosphatase during therapy for Paget's disease. ■ Patients with cancer-related hypercalcemia are frequently dehydrated. Must be adequately hydrated orally and/or IV before treatment is initiated. Hydration with saline is preferred to facilitate renal excretion of calcium and to correct dehydration. A pretreatment urine output of 2 L/day is recommended. Maintain adequate hydration and urine output throughout treatment. ■ Avoid overhydration in patients with compromised cardiovascular status. Observe frequently for signs of fluid overload. Correct hypovolemia before using diuretics. ■ Monitor patients with pre-existing anemia, leukopenia, or thrombocytopenia very carefully during treatment and for the first 2 weeks following treatment. ■ Monitor for S/S of atypical femoral fractures that may occur with minimal or no trauma. Thigh or groin pain may be experienced weeks to months before a fracture appears. Fractures are often bilateral; examine both femurs. ***Osteolytic bone lesions of multiple myeloma:*** Adequately hydrate patients who have marked Bence-Jones proteinuria and dehydration before pamidronate infusion.

Patient Education:

Regular visits and assessment of lab tests imperative. ■ Dietary restriction of calcium and vitamin D may be required. ■ Take only prescribed medications. ■ Report abdominal cramps, chills, confusion, fever, muscle spasms, sore throat, and/or any new medical problems promptly. ■ Report development of bone, joint, or muscle pain promptly. Onset of pain is variable. ■ Avoid pregnancy; use of effective birth control necessary during treatment and for an undetermined time after treatment; see prescribing information.

Maternal/Child:

Category D: should not be used during pregnancy. May cause fetal harm. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established.

Elderly:

Response similar to that seen in younger patients. ■ Use with caution based on age-related impaired organ function and concomitant disease or drug therapy; monitor renal function closely. See Dose Adjustments. ■ Monitor fluid and electrolyte status carefully to avoid overhydration or electrolyte imbalance. Use of lower fluid volume may be required; see Dilution.

DRUG/LAB INTERACTIONS

Use caution when administered with other **potentially nephrotoxic drugs** (e.g., aminoglycosides, cisplatin). ■ Effects may be antagonized by **calcium-containing**

preparations or vitamin D; avoid use. ■ Concurrent use with **thalidomide** may increase risk of renal toxicity in patients with multiple myeloma.

SIDE EFFECTS

Average dose:

Abdominal pain, anemia, anorexia, bone pain, confusion and visual hallucinations (sometimes in conjunction with electrolyte imbalance), constipation, fever (mild and transient), generalized pain, hypertension, hypocalcemia (abdominal cramps, confusion, muscle spasms), infusion site reaction (e.g., induration and pain on palpation, redness, swelling), musculoskeletal pain (bone, joint, and/or muscle pain), pruritus, rash, renal toxicity, seizures, urinary tract infections, vomiting. Fluid overload, hypokalemia, hypomagnesemia, and hypophosphatemia occur frequently with use of concurrent fluid and diuretics. Rare instances of hypersensitivity reactions, including anaphylaxis, angioedema, dyspnea, and hypotension, have occurred. Osteonecrosis (primarily of the jaw) has been reported (see Precautions). Anemia, leukopenia, and thrombocytopenia may occur.

Overdose:

Occurs less frequently with lower dose range (30 to 60 mg). Fever (high), hypocalcemia, hypotension, leukopenia or lymphopenia (fever, chills, sore throat), transient taste perversion. Elevated BUN and CrCl levels and renal tubular necrosis may occur with excessive dose or rate of administration.

Post-Marketing:

Adult respiratory distress syndrome (ARDS); atypical subtrochanteric and diaphyseal femoral fractures; bone, joint, and muscle pain (may be severe and incapacitating); conjunctivitis; focal segmental glomerulosclerosis (including the collapsing variant); glomerulonephropathies; hematuria; hypernatremia; influenza-like symptoms; interstitial lung disease; nephrotic syndrome; orbital inflammation; reactivation of herpes simplex and herpes zoster; renal tubular disorders; tubulointerstitial nephritis.

ANTIDOTE

Keep physician informed of side effects. Some may respond to symptomatic treatment. Magnesium, phosphorus, and potassium may require replacement if depletion too severe. If mild, all will probably return toward normal in 7 to 10 days. For asymptomatic or mild to moderate hypocalcemia (6.5 to 8 mg/100 mL corrected for serum albumin), short-term calcium therapy (e.g., calcium gluconate) may be indicated. Consider discontinuing pamidronate in patients who develop atypical fractures of the femur. Unknown if risk continues after stopping treatment. Discontinue drug for any symptoms of overdose. Monitor serum calcium and use vigorous IV hydration, with or without diuretics, for 2 to 3 days. Monitor intake and output to ensure adequacy and balance. Use short-term IV calcium therapy if indicated. High fever may respond to steroids. RBC transfusions may be required in anemia. Treat anaphylaxis and resuscitate as indicated.

PANCURONIUM BROMIDE BBW

(pan-kyou-**ROH**-nee-um **BRO**-myd)
Neuromuscular blocking agent (nondepolarizing)
Anesthesia adjunct
pH 4

USUAL DOSE

Adjunct to general anesthesia for adults and pediatric patients:

Must be individualized, depending on previous drugs administered and degree and length of muscle relaxation required. Must be used with adequate anesthesia and/or sedation and after unconsciousness induced. Succinylcholine must show signs of wearing off before pancuronium is given. 0.04 to 0.1 mg/kg of body weight initially. 0.01 mg/kg in increments as required to maintain muscle relaxation; usually 25- to 60-minute intervals.

Endotracheal intubation:

0.06 to 0.1 mg/kg.

Support of intubated mechanically ventilated or respiratory-controlled adult ICU patients (unlabeled):

IV bolus injection: 0.1 to 0.2 mg/kg every 1 to 3 hours. ***Continuous infusion:*** Begin with a ***loading dose*** of 0.03 to 0.1 mg/kg followed by a ***maintenance dose*** of 0.06 to 0.1 mg/kg/hr. A lower-end or reduced dose may be indicated if administered more than 5 minutes after the start of an inhalation agent, when steady-state has been achieved, or in patients with organ dysfunction (e.g., impaired renal function). Adjust dose according to clinical assessment of the patient's response. Use of a peripheral nerve stimulator is recommended.

NEONATAL DOSE

Adjunct to general anesthesia:

Extreme sensitivity to pancuronium exists during the first month of life. Begin with a test dose of 0.02 mg/kg and assess responsiveness. See Maternal/Child.

DOSE ADJUSTMENTS

See Drug/Lab Interactions; marked reduction of pancuronium dose may be required. ■ A higher total dose may be required in biliary or hepatic disease, but onset is slower and neuromuscular block is prolonged. ■ Clearance decreased and half-life increased in renal insufficiency. One source recommends administering 50% of a dose if CrCl is between 10 and 50 mL/min; do not use if CrCl is less than 10 mL/min.

DILUTION

May be given undiluted or diluted in D5W, D5/½NS, D5NS, NS, or LR for use as an infusion.

Storage:

Best if stored in refrigerator. Will maintain potency at room temperature for up to 6 months.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Adjunct to general anesthesia:

A single dose over 60 to 90 seconds.

Mechanical ventilation support in ICU:

See Usual Dose for specific rates and criteria.

ACTIONS

A skeletal muscle relaxant. Causes paralysis by interfering with neural transmission at the myoneural junction. Onset of action is dose dependent. Peak effect occurs in 3 to 4 minutes and lasts 30 to 45 minutes. It may take another 30 minutes or up to several hours before complete recovery occurs. Excreted in the urine.

INDICATIONS AND USES

Adjunctive to general anesthesia to facilitate endotracheal intubation and to relax skeletal muscles during surgery or mechanical ventilation.

Unlabeled uses:

Support of intubated, mechanically ventilated, or respiratory-controlled patients in ICU.

CONTRAINDICATIONS

Known hypersensitivity to pancuronium or bromides; first trimester of pregnancy.

PRECAUTIONS

Usually administered by or under the direct observation of the anesthesiologist. Appropriate emergency drugs and equipment for monitoring the patient and responding to any medical emergency must be readily available. ■ Severe anaphylactic reactions have been reported with neuromuscular blocking agents; some have been fatal. Use caution in patients who have had an anaphylactic reaction to another neuromuscular blocking agent (depolarizing or nondepolarizing); cross-reactivity has occurred. ■ Repeated doses may produce a cumulative effect. ■ Impaired pulmonary function or respiratory deficiencies can cause critical reactions. ■ Use caution in impaired liver or kidney function, in patients with tachycardia, and in any patient who might develop adverse effects from an increase in HR. ■ Myasthenia gravis increases sensitivity to drug. ■ Long-term use (i.e., intensive care) may result in prolonged paralysis or skeletal muscle weakness. ■ Acid-base and/or electrolyte imbalance, debilitation, hypoxic episodes, and/or the use of other drugs (e.g., broad-spectrum antibiotics, narcotics, steroids) may prolong the effects of pancuronium.

Monitor:

All uses:

This drug produces apnea. Controlled artificial ventilation with oxygen must be continuous and under direct observation at all times. Maintain a patent airway. ■ Use a peripheral nerve stimulator to monitor response to pancuronium and avoid overdose. ■ Patient may be conscious and completely unable to communicate by any means. Pancuronium has no analgesic or sedative properties. ■ Action is altered by dehydration, electrolyte imbalance, body temperatures, and acid-base imbalance. ■ Hyperkalemia may cause cardiac arrhythmias and increased paralysis. ■ See Precautions and Drug/Lab Interactions.

Mechanical ventilation support in ICU:

Physical therapy is recommended to prevent muscular weakness, atrophy, and joint contracture. Muscular weakness may first be noticed during attempts to wean patients from the ventilator.

Maternal/Child:

Category C: unknown potential hazards to fetus. Benefits must outweigh risks. Not recommended in first trimester. ■ Has caused rare severe skeletal muscle weakness in neonates undergoing mechanical ventilation.

Elderly:

Delay in onset time may be caused by slower circulation time in cardiovascular disease, old age, or edematous states; allow more time for drug to achieve maximum effect.

DRUG/LAB INTERACTIONS

May cause severe arrhythmias with **inhalant anesthetics** (e.g., enflurane, halothane) and in patients on chronic **tricyclic antidepressant therapy** (e.g., amitriptyline [Elavil]). ■ Potentiated by **hypokalemia, some carcinomas, many antibiotics** (e.g., aminoglycosides [kanamycin, gentamicin], bacitracin, colistin [Coly-Mycin S], colistimethate [Coly-Mycin M], polymyxin-B [Aerosporin], tetracyclines, piperacillin), **calcium salts, CO_2, diuretics, diazepam** (Valium) **and other muscle relaxants, digoxin, magnesium sulfate, quinidine, morphine, lidocaine, meperidine, propranolol** (Inderal), **succinylcholine, and others.** May need to reduce dose of pancuronium; use with caution. ■ Recurrent paralysis may occur with **quinidine.** ■ Effects may be decreased by **acetylcholine, aminophylline, anticholinesterases, azathioprine, carbamazepine, and potassium.** ■ **Succinylcholine** must show signs of wearing off before pancuronium is given. Use caution.

SIDE EFFECTS

Increased HR, decrease in mean arterial pressure, prolonged action resulting in respiratory insufficiency or apnea and tachycardia. Airway closure caused by relaxation of epiglottis, pharynx, and tongue muscles. Hypersensitivity reactions are possible. Anaphylaxis, histamine release (e.g., bronchospasm, vasodilation, hypotension, cutaneous flushing), and shock may occur. Muscular weakness and atrophy may occur with long-term use (1 to 3 weeks).

ANTIDOTE

All side effects are medical emergencies. Treat symptomatically. Controlled artificial ventilation must be continuous. Pyridostigmine (Regonol) or neostigmine given with atropine will probably reverse the muscle relaxation. Not effective in all situations; may aggravate severe overdose. Resuscitate as necessary.

PANITUMUMAB BBW

(pan-i-**TUE**-moo-mab)
Vectibix
Antineoplastic
Immunosuppressant
Monoclonal antibody
(EGFR receptor antagonist)
pH 5.6 to 6

USUAL DOSE

Pretreatment:

Verify pregnancy status. Pretesting required. Before initiating treatment, assess *RAS* mutational status in colorectal tumors and confirm the absence of a *RAS* mutation in exon 2 (codons 12 and 13), exon 3 (codons 59 and 61), and exon 4 (codons 117 and 146) of both *KRAS* and *NRAS*; see Precautions. See prescribing information for access to FDA-approved tests. Baseline studies required; see Monitor.

Panitumumab:

6 mg/kg as an infusion once every 14 days.

DOSE ADJUSTMENTS

Upon the first occurrence of a Grade 3 (NCI-CTC/CTCAE) dermatologic reaction, withhold 1 to 2 doses of panitumumab. If the reaction improves to less than Grade 3, re-initiate panitumumab at the original dose. ■ Upon the second occurrence of a Grade 3 (NCI-CTC/CTCAE) dermatologic reaction, withhold 1 to 2 doses of panitumumab. If the reaction improves to less than Grade 3, reinitiate panitumumab at 80% of the original dose. ■ Upon the third occurrence of a Grade 3 (NCI-CTC/CTCAE) dermatologic reaction, withhold 1 to 2 doses of panitumumab. If the reaction improves to less than Grade 3, re-initiate panitumumab at 60% of the original dose. ■ Upon the fourth occurrence of a Grade 3 (NCI-CTC/CTCAE) dermatologic reaction, permanently discontinue panitumumab. ■ Permanently discontinue panitumumab following the occurrence of a Grade 4 dermatologic reaction or for a Grade 3 dermatologic reaction that does not recover after withholding 1 to 2 doses.

DILUTION

Solution may contain a small amount of visible, translucent-to-white, amorphous, and proteinaceous particulates. Do not use if solution is discolored or cloudy or if foreign matter is present. **Do not shake.** Using a 21-gauge or larger gauge (smaller bore) hypodermic needle, withdraw the calculated dose from the vial. Dilute to a total volume of 100 mL with NS. Doses higher than 1,000 mg should be diluted to a volume of 150 mL. (Withdraw a volume of NS equal to the volume of the calculated dose from the infusion bag.) Final concentration should not exceed 10 mg/mL. Mix diluted solution by gentle inversion.

Filters:

Must be administered through a low–protein-binding, 0.2- or 0.22-micron, in-line filter.

Storage:

Store unopened vials in refrigerator (2° to 8° C [36° to 46° F]) until time of use. Protect from direct sunlight. Do not freeze. Diluted solutions should be used within 6 hours of preparation if stored at RT and within 24 hours if stored in refrigerator. Do not freeze. Single-dose vial; discard any unused product after entry into vial.

COMPATIBILITY

Manufacturer states, “Should not be mixed with, or administered as an infusion with, other medicinal products. No other medications should be added to solutions containing panitumumab.”

RATE OF ADMINISTRATION

For IV infusion only. **Do not administer as an IV push or bolus.** Flush line before and after panitumumab administration with NS. Administer with an IV infusion pump using a low–protein-binding, 0.2- or 0.22-micron, in-line filter.

A single dose equally distributed over 60 minutes. If the first infusion is tolerated, administer subsequent infusions over 30 to 60 minutes. Doses over 1,000 mg should be administered over 90 minutes. Reduce rate of infusion by 50% in patients experiencing a Grade 1 or 2 infusion reaction.

ACTIONS

An epidermal growth factor receptor (EGFR) antagonist for IV use, and a human IgG2 kappa monoclonal antibody. EGFR is a transmembrane glycoprotein that is expressed in many normal epithelial tissues, including skin and hair follicles. Overexpression of EGFR is detected in many human cancers, including those of the colon and rectum. Interaction of EGFR with its normal ligands leads to a series of reactions that regulate the transcription of molecules involved with cellular growth and survival, motility, proliferation, and transformation. Panitumumab binds to EGFR on both normal and tumor cells, inhibiting the binding of normal ligands to EGFR. This competitive binding results in inhibition of cell growth, induction of apoptosis, decreased proinflammatory cytokine and vascular growth factor production, and internalization of EGFR. The end result is inhibition of growth and survival of selected human tumor cells that express EGFR. Half-life is approximately 7.5 days (range 3.6 to 10.9 days).

INDICATIONS AND USES

Treatment of patients with wild-type *RAS* (defined as wild-type in both *KRAS* and *NRAS* as determined by an FDA-approved test for this use) metastatic colorectal cancer (mCRC). May be used as first-line therapy in combination with FOLFOX (5-fluorouracil, leucovorin, and oxaliplatin) or as monotherapy following disease progression after prior chemotherapy containing fluoropyrimidine (fluorouracil), oxaliplatin, and irinotecan.

Limitation of use:

Not indicated for the treatment of patients with *RAS* mutant mCRC or for patients whose *RAS* mutation status is unknown.

CONTRAINDICATIONS

None known. See Precautions.

PRECAUTIONS

Panitumumab should be used only for treatment of patients with *KRAS* wild-type mCRC as determined by an FDA-approved test. In studies, patients with *KRAS*-mutant mCRC tumors receiving panitumumab in combination with FOLFOX experienced some overall survival compared with patients receiving FOLFOX alone. Perform the assessment for *KRAS* mutational status in colorectal cancer laboratories with demonstrated proficiency in the technology required for testing. ■ Dermatologic toxicities were reported in 90% of patients and were severe (NCI-CTC/CTCAE Grade 3 or higher) in 15% of patients. Manifestations included dermatitis acneiform, dry skin, erythema, paronychia, pruritus, rash, skin exfoliation, and skin fissures. Severe dermatologic toxicities were complicated by infection. Life-threatening and fatal infectious complications, including necrotizing fasciitis, abscesses requiring incision and drainage, and sepsis, have been observed. Life-threatening and fatal bullous mucocutaneous disease with blisters, erosions, and skin sloughing has also been reported. It is unclear whether these reactions were directly related to EGFR inhibition or to idiosyncratic immune-related effects (e.g., Stevens-Johnson syndrome or toxic epidermal necrolysis). See Dose Adjustments and Antidote. ■ Sunlight may exacerbate dermatologic toxicity. Protection from sun is advised; see Patient Education. ■ Infusion reactions, some severe, have been reported. Fatal reactions have been reported. Administer in a facility with adequate emergency medical equipment and medications for treating these reactions and for responding to any medical emergency; see Rate of Administration and Antidote. ■ Increased mortality and toxicity were seen in studies in which panitumumab was administered in combination with bevacizumab and chemotherapy; see manufacturer's prescribing information. ■ Electrolyte abnormalities have been reported; see Monitor. ■ Fatal and nonfatal cases of interstitial lung disease (ILD) and pulmonary fibrosis have been reported; see Monitor. In patients with a history of interstitial pneumonitis or pulmonary fibrosis or with evidence of interstitial pneumonitis or pulmonary fibrosis, the benefit of therapy versus the risk of pulmonary complications must be considered. ■ Severe diarrhea and dehydration leading to acute renal failure and other complications have been observed in patients treated with panitumumab in combination with chemotherapy. ■ Keratitis and ulcerative keratitis, known risk factors for corneal perforation, have been reported. ■ A protein substance. Potential for immunogenicity exists. Anti-panitumumab antibodies have been detected in a small number of patients. No evidence of altered safety profiles has been confirmed.

Monitor:

Obtain baseline electrolytes and monitor periodically during and for 8 weeks after completion of therapy. Hypomagnesemia, hypocalcemia, and hypokalemia have been reported. Oral or IV electrolyte replacement may be required. ■ Monitor hydration status. ■ Monitor vital signs before, during (as needed), and at the completion of the infusion. ■ Monitor for S/S of hypersensitivity or infusion-related reactions. Severe reactions may include anaphylaxis, bronchospasm, chills, dyspnea, fever, and hypotension; see Side Effects. Mild to moderate infusion reactions may respond to a reduction in the rate of infusion; see Rate of Administration. Utility of premedication to minimize or prevent infusion-related reactions has not been determined. ■ Monitor skin integrity. Monitor patients who develop dermatologic or soft tissue toxicities for the development of inflammatory or infectious sequelae. ■ Monitor lung function. Interrupt therapy in the event of acute onset or worsening of pulmonary symptoms. Discontinue therapy if ILD is confirmed. ■ Monitor for evidence of keratitis or ulcerative keratitis.

Patient Education:

Highly effective contraception required during treatment with panitumumab and for at least 2 months after the last dose of panitumumab. ■ Notify provider of known or suspected pregnancy. ■ May reduce fertility in females of reproductive potential. ■ Review side effects, including dermatologic toxicity, infusion reactions, pulmonary fibrosis, and potential for fetal harm. ■ Promptly report skin or ocular changes, cough, dehydration, diarrhea, dyspnea, infusion-related reactions, or new-onset facial swelling. ■ Diarrhea and dehydration may lead to acute renal failure and electrolyte depletion when panitumumab is administered in combination with chemotherapy. ■ Limit sun exposure during and for 2 months after the last dose of panitumumab. Use of sunscreen and hats recommended. ■ Compliance with periodic lab work required.

Maternal/Child:

Avoid pregnancy; based on its mechanism of action and animal studies, panitumumab administration can result in fetal harm. Human IgG monoclonal antibody and may be transferred across the placenta. Therefore it is possible that panitumumab may be transmitted from the mother to the developing fetus. Appropriate contraceptive measures must be used during treatment with panitumumab and for at least 2 months after the last dose; see Patient Education. ■ Discontinue breast-feeding during and for 2 months after the completion of therapy. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

When used as monotherapy, specific differences in safety and effectiveness compared with younger adults not noted. An increased incidence of serious adverse events and an increased incidence of serious diarrhea were seen in patients over the age of 65 when given panitumumab in combination with FOLFOX.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted.

SIDE EFFECTS

The most commonly reported side effects of panitumumab as **monotherapy** are diarrhea, fatigue, nausea, paronychia, and skin rash with variable presentations. The most common serious reactions, as well as the reactions that lead most often to discontinuation of therapy, were general physical health deterioration and intestinal obstruction. Side effects occurring in 5% or more of patients receiving panitumumab as monotherapy included acne, acneiform dermatitis, cough, dry skin, dyspnea, erythema, exfoliative rash, mucosal inflammation, nail disorders, rash, skin exfoliation, skin fissures, skin ulcer, stomatitis, and vomiting. The most commonly reported side effects when panitumumab was used **in combination with chemotherapy** were acneiform dermatitis, anorexia, asthenia, diarrhea, dry skin, hypokalemia, hypomagnesemia, mucosal inflammation, paronychia, pruritus, rash, and stomatitis. The most common serious reactions were diarrhea and dehydration. The most commonly reported side effects leading to discontinuation were acneiform dermatitis, diarrhea, fatigue, hypersensitivity, paresthesia, and rash. Side effects occurring in 5% or more of patients receiving panitumumab in combination with chemotherapy included acne, alopecia, conjunctivitis, dehydration, epistaxis, erythema, nail disorders, palmar-plantar erythrodysesthesia syndrome, skin fissures, and weight decrease. Other serious but less frequently reported side effects as outlined in Precautions included acute renal failure, infusion reactions, interstitial lung disease/pulmonary fibrosis, and ocular toxicity.

Post-Marketing:

Angioedema, infusion reactions (fatal), keratitis/ulcerative keratitis, life-threatening and fatal bullous mucocutaneous disease, and skin necrosis.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Replace electrolytes parenterally or orally as indicated. Reduce infusion rate by 50% if a mild or moderate (Grade 1 or 2) infusion reaction occurs. Discontinue panitumumab for a serious infusion reaction (Grade 3 or 4). Depending on the severity and/or persistence of the reaction, discontinue permanently. Hold or discontinue panitumumab if dermatologic or soft tissue toxicities Grade 3 or higher occur, if they are considered intolerable, or if severe or life-threatening inflammatory or infectious complications occur. See Dose Adjustments for criteria to resume or permanently discontinue treatment. Discontinue if ILD is confirmed. Interrupt or discontinue panitumumab infusion for acute or worsening keratitis. Treat hypersensitivity or infusion reaction as indicated (e.g., oxygen, antihistamines [e.g., diphenhydramine], epinephrine, corticosteroids, vasopressors [e.g., dopamine], ventilation equipment, and/or fluids). Resuscitate as necessary.

PANTOPRAZOLE SODIUM

(pan-**TOH**-prah-zohl **SO**-dee-um)
Protonix IV
Proton pump inhibitor (PPI) Substituted benzimidazole
pH 9 to 10.5

USUAL DOSE

Given as an alternative to continued oral therapy. Resume oral therapy as soon as practical.

Treatment of gastroesophageal reflux disease (GERD):

40 mg as an infusion once daily for 7 to 10 days.

Treatment of Zollinger-Ellison syndrome (ZES):

80 mg as an infusion every 12 hours. Adjust to patient needs based on acid output measurements. If an increased dose is required, 80 mg every 8 hours is expected to maintain gastric acid output at less than 10 mEq/hr. Daily doses in excess of 240 mg or for more than 6 days have not been studied.

Upper GI bleed (unlabeled):

80 mg as an IV injection followed by a continuous infusion of 8 mg/hr for 72 hours.

DOSE ADJUSTMENTS

No dose adjustments are necessary based on race or gender; in the elderly; in patients with mild, moderate, or severe renal insufficiency; in patients on hemodialysis; or in patients with mild to severe impaired hepatic function. Oral doses higher than 40 mg/day have not been studied in patients with hepatic impairment.

DILUTION

40-mg dose:

Reconstitute each single dose with 10 mL NS. May be given as an injection or further diluted with 100 mL D5W, NS, or LR to achieve a final concentration of approximately 0.4 mg/mL for infusion.

80-mg dose:

Combining of two 40-mg vials is required; reconstitute each 40-mg vial with 10 mL NS. May be given as an injection, or this total 80-mg dose may be further diluted with 80 mL D5W, NS, or LR (a total volume of 100 mL) to achieve a final concentration of approximately 0.8 mg/mL for infusion.

Filters:

No longer required.

Storage:

Store unopened vials at CRT. Protect from light. Do not freeze reconstituted product. Vials reconstituted for the 2-minute infusion may be stored for up to 24 hours at RT. Vials reconstituted for the 15-minute infusion may be stored for up to 6 hours at RT prior to further dilution. Fully diluted solution may then be stored at RT but must be used within 24 hours of initial reconstitution. Protection from light is not required for reconstituted or fully diluted solutions.

COMPATIBILITY

Administer through a dedicated line or through a **Y-site**. Should not be simultaneously administered through the same line with other intravenous solutions. See Rate of Administration. ***Discontinue if discoloration or precipitation occurs with any drug at the Y-site.***

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Flush IV line before and after administration of pantoprazole with **compatible** infusion solutions (D5W, NS, or LR).

Concentration determines the rate of administration.

40 mg/10 mL or 80 mg/20 mL:

As an injection evenly distributed over at least 2 minutes.

40 mg/100 mL or 80 mg/100 mL:

As an infusion evenly distributed over at least 15 minutes (approximately 7 mL/min).

ACTIONS

A proton pump inhibitor (PPI) that suppresses the final step in gastric acid production. Acts at the secretory surface of the gastric parietal cell. Inhibits both basal and stimulated gastric acid secretion irrespective of the stimulus. Does not accumulate and pharmacokinetics are not altered with multiple daily dosing. Onset of antisecretory activity is within 15 to 30 minutes. Half-life is approximately 1 hour. However, duration of antisecretory effect persists longer than 24 hours. Distributed mainly in extracellular fluid. Highly bound by serum protein (primarily albumin). Extensively metabolized in the liver through the cytochrome P_{450} system (primarily through CYP2C19 and, to a lesser extent, through CYP3A4, 2D6, and 2C9). Metabolism is independent of the route of administration (intravenous or oral). Primarily excreted in urine with some excretion in feces. Secreted in breast milk.

INDICATIONS AND USES

Short-term treatment (7 to 10 days) of adult patients with gastroesophageal reflux disease (GERD) and a history of erosive esophagitis, as an alternative to oral therapy. ■ Treatment of pathologic hypersecretory conditions, including Zollinger-Ellison syndrome in adults.

Unlabeled uses:

Peptic ulcer disease treatment and secondary prevention (upper GI bleed).

CONTRAINDICATIONS

Known hypersensitivity to pantoprazole, esomeprazole, omeprazole, or any component of the formulation. Patients receiving rilpivirine-containing products.

PRECAUTIONS

For IV use only; do not give IM or SC. ■ Gastric malignancy may be present even though patient's symptoms improve with pantoprazole therapy. Consider additional follow-up and diagnostic testing in adult patients who have a suboptimal response or an early symptomatic relapse after completing treatment with a PPI. In older patients, also consider an endoscopy. ■ Formulation contains edetate disodium, which can chelate zinc; see Monitor. ■ Discontinue as soon as the patient is able to resume treatment with pantoprazole delayed-release tablets or oral suspension. Safety for treatment of patients with GERD and a history of erosive esophagitis for more than 10 days has not been demonstrated. ■ Data on safe and effective dosing for other conditions (including life-threatening upper GI bleeds) not available. 40 mg IV of pantoprazole daily does not raise gastric pH levels sufficiently to treat such life-threatening conditions. ■ Hypersensitivity reactions, including anaphylaxis and severe skin reactions (e.g., erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis), have been reported. ■ May be associated with an increased risk for osteoporosis-related fractures of the hip, wrist, or spine. Risk increased in patients receiving high-dose (multiple daily doses) and long-term therapy (a year or longer). Use lowest dose and shortest duration of therapy appropriate for the condition being treated. ■ Hypomagnesemia (symptomatic and asymptomatic) has been reported in patients treated with proton pump inhibitors (PPIs) for at least 3 months and, in most cases, after a year of treatment. Serious adverse events, including arrhythmias, seizures, and tetany, have occurred. Discontinuation of the PPI and magnesium replacement have been required. ■ Associated with increased risk of fundic gland polyps, which increases with long-term use, especially beyond 1 year. Most patients who developed fundic gland polyps were asymptomatic, and fundic gland polyps were identified on endoscopy. Use the shortest duration of therapy appropriate for the condition being treated. ■ Serum chromogranin A (CgA) levels increase secondary to drug-induced decreases in gastric acidity; see Drug/Lab Interactions. ■ May be associated with an increased risk of

Clostridium difficile–associated diarrhea (CDAD), especially in hospitalized patients. Consider in patients who develop diarrhea that does not improve. Use lowest dose and shortest duration of therapy appropriate for the condition being treated. ■ Acute interstitial nephritis has been observed and is generally attributed to an idiopathic hypersensitivity reaction. May occur at any time during therapy. Discontinue pantoprazole if it occurs. ■ Cutaneous lupus erythematosus (CLE) and systemic lupus erythematosus (SLE) have been reported in patients taking PPIs. These events have occurred both as new onset and as an exacerbation of existing autoimmune disease. CLE is more common and occurs weeks to years after continuous PPI therapy in patients ranging from infants to the elderly. PPI-induced SLE is usually milder than non–drug-induced SLE and occurs days to years after initiating PPI therapy, primarily in patients ranging from young adults to the elderly. Most patients present with rash; however, arthralgia and cytopenia have also been reported. Discontinue pantoprazole if S/S of CLE or SLE develop, and refer patient to the appropriate specialist. Most patients improve within 4 to 12 weeks of PPI discontinuation. ■ See Drug/Lab Interactions.

Monitor:

Observe for S/S of a hypersensitivity reaction and/or severe skin reaction (e.g., acute interstitial nephritis, anaphylactic shock, anaphylaxis, angioedema, bronchospasm, urticaria). ■ Monitor vital signs and pain levels. ■ Concomitant use of antacids may be indicated. ■ In hypersecretory states, acid output measurements may be indicated to guide dose adjustment. ■ Monitor injection site. Thrombophlebitis has been reported. ■ Zinc supplementation may be indicated in patients who are prone to zinc deficiency; see Precautions. ■ Monitoring of magnesium levels may be indicated with prolonged PPI therapy; see Precautions and Drug/Lab Interactions. ■ Serologic testing (e.g., ANA titers) may be indicated in patients who present with S/S of CLE or SLE. ■ Change to oral dosing when appropriate. ■ See Drug/Lab Interactions.

Patient Education:

Review prescription and nonprescription drugs with your physician. ■ Oral route preferred. ■ Promptly report cardiovascular or neurologic symptoms, including dizziness, palpitations, seizures, or tetany; may be signs of hypomagnesemia. ■ Promptly report any adverse effects, including S/S of hypersensitivity reactions or diarrhea.

Maternal/Child:

Available data from observational studies failed to demonstrate an association of adverse pregnancy-related outcomes and pantoprazole use. Use during pregnancy only when clearly needed. ■ Use caution during breast-feeding. Has been detected in breast milk. Effects on milk production are unknown. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly:

Safety and effectiveness similar to that of younger patients.

DRUG/LAB INTERACTIONS

Concurrent use with **rilpivirine-containing products** (e.g., rilpivirine, Complera [emtricitabine, rilpivirine, tenofovir disoproxil fumarate], Juluca [dolutegravir, rilpivirine], Odefsey [emtricitabine, rilpivirine, tenofovir alafenamide]) is contraindicated. ■ Because of profound and long-lasting inhibition of gastric acid secretion, pantoprazole may interfere with the **absorption of drugs in which gastric pH is an important determinant of their bioavailability.** Absorption of **atazanavir, dasatinib, erlotinib, iron salts, ketoconazole, itraconazole, mycophenolate mofetil,** and **nilotinib** can decrease. ■ Increases in INR and PT have been reported when administered concurrently with **warfarin**; monitoring of INR and PT indicated. Increases in INR and PT may lead to abnormal bleeding and death. Dose adjustment of warfarin may be needed to maintain target INR range. ■ The effect of proton pump inhibitors on antiretroviral drugs is variable. Coadministration of proton pump inhibitors results in a significant reduction in **atazanavir** or **nelfinavir** plasma concentrations, which may result in a loss of their therapeutic effect and the development of drug resistance. Avoid concomitant use with **nelfinavir**. See prescribing information for atazanavir for dosing information. Increased exposure of **other antiretroviral drugs** (e.g., saquinavir) when used together with pantoprazole sodium may increase toxicity of the antiretroviral drugs. ■ Long-term use may increase the risk of **digoxin** toxicity secondary to hypomagnesemia. ■ Patients on long-term therapy receiving concomitant **diuretic therapy** may be at increased risk for hypomagnesemia. ■ Concomitant use of proton pump inhibitors with high-dose **methotrexate** may elevate and prolong serum concentrations of methotrexate and/or its metabolite. May lead to methotrexate toxicity; consider withdrawal of pantoprazole. ■ Concomitant administration of pantoprazole and clopidogrel had no clinically significant effect on clopidogrel-induced platelet aggregation. ■ Studies suggest that with concurrent use, the metabolism and serum concentrations of pantoprazole are not significantly altered by other drugs metabolized by the cytochrome P_{450} system. ■ CgA levels increase secondary to PPI-induced decreases in gastric acidity. Increased CgA levels may cause false-positive results in diagnostic investigations for neuroendocrine tumors. Stop pantoprazole treatment at least 14 days before assessing CgA levels and consider repeating the test if initial CgA levels are high (same commercial laboratory should be used). ■ May cause false-positive **urine screening test for tetrahydrocannabinol** (THC).

SIDE EFFECTS

The most frequently occurring side effects are abdominal pain, arthralgias, diarrhea, dizziness, flatulence, headache, nausea, and vomiting. Abscess, blurred vision, chest pain, confusion, dyspnea, gastroenteritis, hemorrhage, hyperglycemia, hypokinesia, increased salivation, injection site reactions including thrombophlebitis, pruritus, rash, speech disorder, tinnitus, transient elevations of serum transaminase, urinary tract infection, and vertigo are reported. Numerous other side effects have been associated with oral pantoprazole.

Post-Marketing:

Agranulocytosis, asthenia, bone fracture, CDAD, CLE, confusion, fatigue, fundic gland polyps, hallucinations, hepatocellular damage leading to jaundice and hepatic failure, hypersensitivity reactions (e.g., anaphylaxis, angioedema), hypomagnesemia, hyponatremia, insomnia, interstitial nephritis, malaise, pancytopenia, rhabdomyolysis, severe dermatologic reactions (e.g., erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis [some fatal]), SLE, somnolence, taste disorders, weight changes.

ANTIDOTE

Keep physician informed of all side effects. May be treated symptomatically. Discontinue and initiate appropriate treatment if S/S associated with serious reactions listed in post-marketing reports occur; see Side Effects. Adverse effects from overdose (up to 240 mg/day in healthy subjects) did not occur during clinical trials. Not removed by hemodialysis.

PAPAVERINE HYDROCHLORIDE

(pah-**PAV**-er-een hy-droh-**KLOR**-eyed)
Vasodilator (peripheral)
pH 3 to 4.5

USUAL DOSE

1 to 4 mL (30 to 120 mg) every 3 hours as indicated. Second dose may be given in 10 minutes only when treating extrasystoles.

PEDIATRIC DOSE

1.5 mg/kg of body weight every 6 hours; see Maternal/Child.

DOSE ADJUSTMENTS

See Drug/Lab Interactions.

DILUTION

May be given undiluted or may be diluted in an equal amount of SWFI. Usually not added to IV solutions. May be given through Y-tube or three-way stopcock of infusion set.

COMPATIBILITY

Will form a precipitate with LR.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

1 mL (30 mg) or fraction thereof over 2 minutes. Rapid IV injection may cause death.

ACTIONS

A nonnarcotic opium alkaloid, it is a direct smooth muscle relaxant and antispasmodic. Relaxation is noted in vascular system and bronchial musculature and in GI, biliary, and urinary tracts. More effective on muscle in spasm, it has an affinity for the smooth muscle of blood vessels. Affects cardiac muscle to depress conduction and increase refractory period. Improved circulation and muscle relaxation decrease pain. Metabolized in the liver and excreted in the urine.

INDICATIONS AND USES

Vascular spasm associated with an acute myocardial infarction. ■ Peripheral or pulmonary embolism. ■ Peripheral vascular disease and cerebral angiospastic states. ■ Visceral spasm of ureteral, biliary, or GI colic. ■ Angina pectoris.

CONTRAINDICATIONS

Complete AV heart block.

PRECAUTIONS

Rarely used; active therapeutic value is questioned. ■ Rapid IV injection may cause death. ■ IM injection is preferred. ■ Use with caution in glaucoma and impaired liver function. ■ Large doses can depress AV and intraventricular conduction, resulting in arrhythmias.

Monitor:

Observe patient continuously; monitor vital signs. ■ See Drug/Lab Interactions.

Patient Education:

Avoid alcohol and other CNS depressants. ■ May cause dizziness and drowsiness; request assistance for ambulation. ■ Use caution in any task requiring alertness.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding and in pediatric patients not established.

Elderly:

Risk of hypothermia may be increased.

DRUG/LAB INTERACTIONS

May be used with **narcotics** if the relaxant effect is not adequate to relieve discomfort. Narcotic dosage should be reduced. ■ Antagonizes effects of **levodopa.**

SIDE EFFECTS

Blurred or double vision, diaphoresis, discomfort (generalized), flushing, hypertension (slight), hypotension, respiratory depth increase, scleral jaundice, sedation, tachycardia.

Major:

Respiratory depression, seizures, ventricular ectopic rhythms, sudden death.

ANTIDOTE

Notify the physician of any minor side effects. If minor symptoms progress or any major side effect appears, discontinue the drug immediately and notify the physician. Treatment of toxicity will be symptomatic and supportive. Consider diazepam or phenytoin for convulsions. Anesthesia with thiopental and a neuromuscular blocking agent may be required. Use dopamine for hypotension. Calcium gluconate may reduce toxic cardiovascular effects. Monitor ECG. Resuscitate as necessary.

PARICALCITOL

(pair-ee-**KAL**-sih-tohl)
Zemplar
Vitamin D analog

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Before treatment, ensure calcium is not above the upper limit of normal.

Paricalcitol:

Recommended initial dose is 0.04 to 0.1 mcg/kg (2.8 to 7 mcg) administered no more frequently than every other day at any time during dialysis. The maximum daily adult dose is 0.24 mcg/kg. Target the maintenance dose to intact parathyroid hormone (PTH) levels within the desired therapeutic range and serum calcium within normal limits.

Information supplied by the manufacturer suggests that the relative dosing of paricalcitol to calcitriol is 4:1. When converting a patient from calcitriol to paricalcitol, the initial dose of paricalcitol should be four times greater than the patient’s dose of calcitriol.

PEDIATRIC DOSE

Dose recommendations are based on severity of disease in addition to body weight. A dose is administered at any time during dialysis.

Pediatric patients 5 years of age and older:

Administer three times per week, no more frequently than every other day, at any time during dialysis. Target the maintenance dose to intact PTH levels within the desired therapeutic range and serum calcium within normal limits.

Baseline iPTH level less than 500 pg/mL:

0.04 mcg/kg 3 times a week.

Baseline iPTH level equal to or greater than 500 pg/mL:

0.08 mcg/kg 3 times a week.
See Dose Adjustments.

DOSE ADJUSTMENTS

Adults:

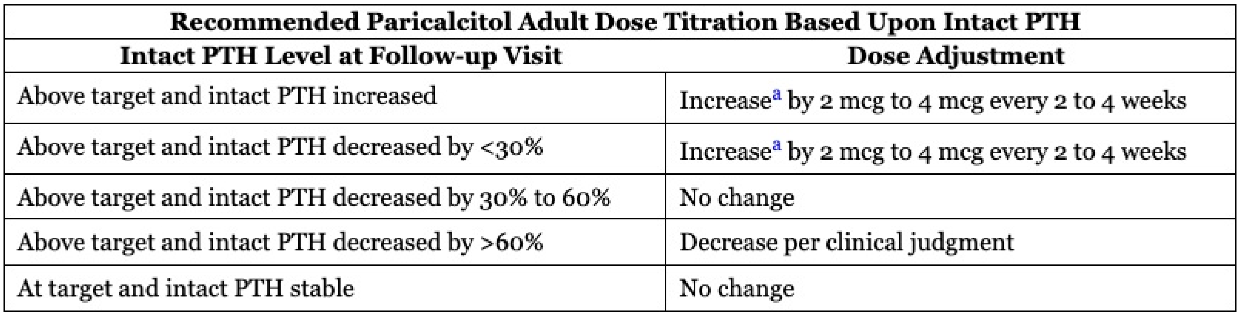
Monitor serum calcium, phosphorus, and calcium × phosphorus product (Ca × P) frequently during any dose adjustment period. See Monitor.

Pediatric patients:

Adjust dose in 0.04-mcg/kg increments based on the levels of serum iPTH, calcium, and Ca × P.

Adults and pediatric patients:

Incremental dosing must be individualized and commensurate with PTH, serum calcium, and phosphorus levels. ■ Titrate the dose based on intact PTH. Before raising the dose, ensure serum calcium is within normal limits. ■ Suspend or decrease the dose if intact PTH is persistently and abnormally low to reduce the risk of adynamic bone disease or if serum calcium is consistently above the normal range to reduce the risk of hypercalcemia. If dose suspension is necessary, restart at a reduced dose after laboratory values have normalized. ■ Dose adjustment and increased monitoring may be necessary when given concomitantly with drugs that may increase the risk of hypercalcemia. Dose adjustment as well as increased monitoring of serum calcium and intact PTH may be necessary when given concomitantly with strong CYP3A inhibitors; see Drug/Lab Interactions. ■ No dose adjustment required in patients with mild or moderate hepatic function. Has not been studied in patients with severe hepatic impairment. ■ The following chart is a suggested approach to dose titration.



Recommended Paricalcitol Adult Dose Titration Based Upon Intact PTH

Intact PTH Level at Follow-up Visit	Dose Adjustment
Above target and intact PTH increased	Increase[a] by 2 mcg to 4 mcg every 2 to 4 weeks
Above target and intact PTH decreased by <30%	Increase[a] by 2 mcg to 4 mcg every 2 to 4 weeks
Above target and intact PTH decreased by 30% to 60%	No change
Above target and intact PTH decreased by >60%	Decrease per clinical judgment
At target and intact PTH stable	No change

[a] The maximum daily adult dose is 0.24 mcg/kg.

Recommended Paricalcitol Pediatric Dose Titration Based on Intact PTH Patients 5 Years of Age and Older	
Intact PTH Level at Follow-up Visit	**Dose Adjustment**
Above target and intact PTH decreased by <30%	Increase by 0.04 mcg/kg every 2 to 4 weeks
Intact PTH ≥150 pg/mL and decreased by 30% to 60%	No change
Intact PTH less than 150 pg/mL or decreased by >60%	Decrease by 0.04 mcg/kg weekly, or by 50% if decreased dose equals zero

DILUTION

May be given undiluted. Available as a solution in a 2 mcg/mL and 5 mcg/mL single-dose vial and a 10 mcg/2 mL multiple-dose vial.

Filters:

Not required by manufacturer; no further data available.

Storage:

Store single-dose and multidose vials at CRT before use. Discard unused portions of single-dose vials. Multidose vial is stable for up to 7 days at CRT after entry into vial.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer as an IV injection through a hemodialysis vascular access port at any time during dialysis. May be administered IV if an access port is unavailable.

ACTIONS

A synthetically manufactured active vitamin D analog. Studies have demonstrated that paricalcitol's biologic actions are mediated through binding of the vitamin D receptor (VDR), which results in the selective activation of vitamin D responsive pathways. Vitamin D and paricalcitol reduce PTH levels by inhibiting PTH synthesis and secretions. Studies suggest that paricalcitol may cause less hypercalcemia and hyperphosphatemia than calcitriol. Serum paricalcitol levels decrease rapidly after a bolus injection. Extensively bound to plasma proteins. Extensively metabolized by multiple hepatic and nonhepatic enzymes. Mean half-life is approximately 15 hours. Eliminated primarily by hepatobiliary excretion in feces and, to a much smaller extent, by the kidneys.

INDICATIONS AND USES

Prevention and treatment of secondary hyperparathyroidism in patients 5 years of age and older with chronic kidney disease (CKD) and on dialysis.

CONTRAINDICATIONS

Patients with evidence of vitamin D toxicity, hypercalcemia, or known hypersensitivity to paricalcitol or any of the active ingredients in this product; see Precautions.

PRECAUTIONS

Hypercalcemia may occur during treatment. Severe hypercalcemia may require emergency attention. If clinically significant hypercalcemia develops, dose should be reduced or held. Acute hypercalcemia may increase the risk of cardiac arrhythmias and seizures and may potentiate the effects of digitalis on the heart. ■ Hypercalcemia can increase the risk of digitalis toxicity. Chronic hypercalcemia can lead to generalized vascular calcification and other soft tissue calcification. See Side Effects and Antidote. ■ Hypercalcemia may be exacerbated by concomitant administration of high doses of calcium-containing preparations, thiazide diuretics, or other vitamin D compounds. High intake of calcium and phosphate concomitantly with vitamin D compounds may lead to hypercalciuria and hyperphosphatemia. ■ Adynamic bone disease with subsequent increased risk of fractures may develop if PTH levels are suppressed to abnormally low levels.

Monitor:

During initiation of therapy or when adjusting a dose, obtain baseline serum calcium and phosphorus levels and determine levels at least twice a week. Once dosage has been established, serum calcium and phosphorus should be monitored at least monthly. See Dose Adjustments. ■ Calculate Ca × P (should be less than 75). ■ Measurements of serum or plasma PTH are recommended every 2 to 4 weeks after initiation of therapy or dose adjustment. ■ Monitor for signs and symptoms of hypercalcemia and digitalis toxicity. See Side Effects.

Patient Education:

Inform physician of all medications, including prescription and nonprescription drugs, and supplements being taken. ■ Routine monitoring of laboratory parameters (e.g., calcium and intact PTH) will need to be done during treatment. ■ Report symptoms of hypercalcemia promptly (e.g., constipation, difficulty thinking clearly, fatigue, increased thirst, increased urination, loss of appetite, nausea or vomiting, weight loss). Dose adjustment or treatment may be required. Strict adherence to dietary supplementation of calcium and restriction of phosphorus is required to ensure optimal effectiveness of therapy. Phosphate-binding compounds (e.g., calcium acetate, sevelamer) may be needed to control serum phosphorus levels in patients with CKD, but excessive use of aluminum-containing products (e.g., aluminum hydroxide gel) should be avoided.

Maternal/Child:

Data are limited for use in pregnant women. There are risks to the mother and fetus associated with CKD in pregnancy. ■ No information available on the presence of paricalcitol in human milk, the effects of the drug on the breast-fed infant, or the effects of the drug on milk production. ■ Has not been studied in pediatric patients under 5 years of age.

Elderly:

Studies did not include sufficient numbers of subjects age 65 years and older to determine whether they respond differently from younger subjects. In general, dose selection should be cautious, usually starting at the low end of the dosing range, reflecting the greater frequency of decreased hepatic or cardiac function and of concomitant disease or other drug therapy.

DRUG/LAB INTERACTIONS

Paricalcitol is partially metabolized by the **cytochrome P_{450} enzyme CYP3A.** Use with caution when administered concomitantly **with known inhibitors of this enzyme** (e.g., atazanavir, boceprevir, clarithromycin, conivaptan, grapefruit juice, indinavir, itraconazole, ketoconazole, lopinavir/ritonavir, nefazodone, nelfinavir, posaconazole, ritonavir, saquinavir, voriconazole). ■ Digitalis toxicity is potentiated by hypercalcemia. Monitor for digitalis toxicity and increase frequency of serum calcium monitoring when initiating or adjusting the dose of paricalcitol. ■ **Phosphate or vitamin D–related compounds** should not be taken concomitantly with paricalcitol; see Precautions. ■ Hypercalcemia may be exacerbated by concomitant administration of high doses of calcium-containing preparations, thiazide diuretics, or other vitamin D compounds; requires more frequent monitoring of calcium and may require dose adjustments. ■ May reduce **serum total alkaline phosphatase** levels.

SIDE EFFECTS

The most commonly reported side effects include arthralgia, chills, dry mouth, edema, fever, gastrointestinal hemorrhage, influenza, malaise, nausea, palpitations, pneumonia, sepsis, and vomiting. Many other side effects occurred in fewer than 2% of patients. Overdose or chronic administration may lead to hypercalcemia. Signs and symptoms of vitamin D intoxication associated with hypercalcemia include: **Early:** bone pain, constipation, dry mouth, headache, metallic taste, muscle pain, nausea, somnolence, vomiting, and weakness. **Late:** Anorexia, cardiac arrhythmias, conjunctivitis (calcific), death, decreased libido, ectopic calcification, elevated AST and ALT, elevated BUN, hypercholesterolemia, hypertension, hyperthermia, overt psychosis (rare), pancreatitis, photophobia, pruritus, rhinorrhea, somnolence, and weight loss.

Post-Marketing:

Hypersensitivity reactions (e.g., angioedema [including laryngeal edema]), rash, urticaria.

Overdose:

Overdose may lead to hypercalcemia, hypercalciuria, and hyperphosphatemia.

ANTIDOTE

Notify physician of any side effects. Treatment should consist of general supportive measures and serial serum electrolyte determinations (especially calcium). Monitor rate of urinary calcium excretion. Treatment of patients with clinically significant hypercalcemia consists of immediate dose reduction or interruption of the therapy and includes a low-calcium diet, withdrawal of calcium supplements, patient mobilization, attention to fluid and electrolyte imbalances, assessment of electrocardiographic abnormalities (critical in patients receiving digoxin), and hemodialysis or peritoneal dialysis against a calcium-free dialysate, as warranted. Monitor serum calcium levels frequently until calcium levels return to within normal limits. Paricalcitol may be restarted at a lower dose when serum calcium levels return to within normal limits. Not significantly removed by dialysis.

PATISIRAN

(pat-i-**SIR**-an)
Onpattro
siRNA
pH ~7

USUAL DOSE

Premedication:

Administer an IV corticosteroid, oral acetaminophen, an IV H_1-blocker, and an IV H_2-blocker at least 60 minutes before the start of the patisiran infusion to reduce the risk of infusion-related reactions (IRRs). If premedications are not available or not tolerated intravenously, equivalents may be administered orally. Corticosteroid may be reduced by 2.5-mg increments to a minimum dose of 5 mg of dexamethasone (IV), or equivalent, for patients who are tolerating their patisiran infusions but are experiencing adverse reactions related to the corticosteroid premedication. Some patients may require additional or higher doses of one or more of the premedications to reduce the risk of IRRs.

Patisiran:

Dosing is based on actual body weight.

Patients less than 100 kg:

0.3 mg/kg as an IV infusion once every 3 weeks.

Patients weighing 100 kg or more:

30 mg as an IV infusion once every 3 weeks.

If a dose is missed, administer patisiran as soon as possible. If administered within 3 days of the scheduled dose, continue dosing according to the patient's original schedule. If administered more than 3 days after the scheduled dose, continue dosing every 3 weeks thereafter.

DOSE ADJUSTMENTS

Some patients who experience IRRs may benefit from a slower infusion rate or from additional or higher doses of one or more of the premedications with subsequent infusions to reduce the risk of IRRs. ■ No dose adjustments needed based on age, race, or gender or for patients with mild hepatic impairment or mild to moderate renal impairment. ■ Has not been studied in patients with moderate or severe hepatic impairment or severe renal impairment or ESRD.

DILUTION

Available as a lipid complex solution in 10 mg/5 mL (2 mg/mL) single-dose vials. Calculate the required dose of patisiran based on the patient's weight. Remove patisiran from refrigerator and allow to warm to RT. Do not shake or vortex. Do not use if discolored or if foreign particles are present. A white to off-white coating may be observed on the inner surface of the vial; product quality is not affected. Using aseptic technique, withdraw the entire contents of one or more vials into a single sterile syringe. Filter patisiran through a sterile 0.45-micron polyethersulfone (PES) syringe filter into a sterile container. Withdraw the calculated dose (required volume) of filtered patisiran using a sterile syringe. Dilute the required volume of filtered patisiran by injecting it into an infusion bag containing NS for a total volume of 200 mL. Use infusion bags that are di(2-ethylhexyl) phthalate–free (DEHP-free). Gently invert the bag to mix. Do not shake.

Filters:

Filter through a 0.45-micron PES syringe filter before dilution. An infusion set containing a 1.2-micron polyethersulfone (PES) in-line infusion filter is required for administration.

Storage:

Store vials at 2° to 8° C (36° to 46° F). Do not freeze. Discard vial if it has been frozen. If refrigeration is not available, store at RT up to 25° C (77° F) for up to 14 days. Diluted patisiran should be administered immediately. If not used immediately, store the infusion bag at RT (up to 30° C [86° F]) for up to 16 hours (including infusion time). Do not freeze. Discard any unused portion.

COMPATIBILITY

Manufacturer states, "Do not mix or dilute with other drugs."

RATE OF ADMINISTRATION

Use of a dedicated free-flowing venous access line with an infusion set and lines that are DEHP-free and contain a 1.2-micron polyethersulfone (PES) in-line infusion filter is required. Administer via an ambulatory infusion pump over approximately 80 minutes at an initial rate of approximately 1 mL/min for the first 15 minutes, then increase to approximately 3 mL/min for the remainder of the infusion. The duration of time may be extended in the event of an IRR. After completion of the infusion, flush with NS to ensure all patisiran has been administered.

ACTIONS

Patisiran is a double-stranded small interfering ribonucleic acid (siRNA) that causes degradation of mutant and wild-type transthyretin (TTR) messenger RNA (mRNA) through RNA interference, which results in a reduction of serum TTR protein and TTR protein deposits in tissue. Plasma protein binding is low. Terminal half-life is 1.4 to 5 days. Patisiran is mainly cleared through metabolism. Less than 1% is excreted unchanged in the urine.

INDICATIONS AND USES

Treatment of polyneuropathy of hereditary transthyretin-mediated amyloidosis in adults.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Infusion-related reactions (IRRs) have been reported. Most patients who experienced an IRR experienced the first IRR within the first two infusions. The frequency of IRRs decreased over time. ■ Patisiran treatment leads to a decrease in serum vitamin A levels. Supplementation with the daily allowance of vitamin A is advised. Higher doses than the recommended daily amount of vitamin A should not be given to try to achieve normal serum vitamin A levels during treatment. Serum vitamin A levels do not reflect the total vitamin A in the body. ■ As with all therapeutic proteins, there is a potential for immunogenicity.

Monitor:

Monitor patients during and, if clinically indicated, after the infusion for S/S of IRRs (e.g., abdominal pain, back pain, dyspnea, flushing, headache, and nausea). ■ Monitor the infusion site for extravasation. ■ Monitor for decreased serum vitamin A levels. Referral to an ophthalmologist is indicated if ocular symptoms suggestive of vitamin A deficiency (e.g., night blindness) develop. ■ See Antidote.

Patient Education:

Immediately report S/S of an IRR (e.g., chest pain, facial edema, flushing, increased heart rate, rash, or shortness of breath). ■ Take the recommended daily allowance of vitamin A. Contact your health care provider if ocular symptoms suggestive of vitamin A deficiency develop (e.g., night blindness). ■ Report pregnancy or plans to become pregnant while taking patisiran. If patient is of childbearing potential, advise of the potential risk to the fetus.

Maternal/Child:

There are no available data on patisiran use in pregnant women. Patisiran leads to a decrease in serum vitamin A levels, and vitamin A supplementation is advised. Vitamin A is essential for normal embryofetal development; however, excessive levels of vitamin A are associated with adverse developmental effects. Consider risk versus benefit. ■ There is no information regarding the presence of patisiran in human milk, the effects on the breast-fed infant, or the effects on milk production. Consider risk versus benefit. ■ Safety and effectiveness for use in pediatric patients have not been established.

Elderly:

No overall differences in safety or effectiveness were observed between elderly patients and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been performed.

SIDE EFFECTS

The most frequently reported side effects were infusion-related reactions and upper respiratory tract infections. Other side effects included arthralgia, AV heart block, bronchitis, dyspepsia, dyspnea, erythema, extravasation (e.g., burning sensation, cellulitis, dermatitis [subcutaneous inflammation], erythema or injection site redness, infusion or injection site swelling, injection site pain, phlebitis, or thrombophlebitis), muscle spasms, ocular side effects (e.g., blurred vision, dry eyes, vitreous floaters), and vertigo.

ANTIDOTE

Notify physician of any side effects. Suspected extravasation should be managed according to local standard practice for nonvesicants. If an IRR occurs, slow or interrupt the infusion and institute medical management (e.g., corticosteroids or other symptomatic treatment) as clinically indicated. If the infusion is interrupted, consider resuming at a slower infusion rate only if symptoms have resolved. If serious or life-threatening IRR, the infusion should be discontinued and not resumed.

PEGASPARGASE ■ ASPARAGINASE *Erwinia chrysanthemi*

(peg-**AS**-par-gays) ■ (as-**PAR**-a-jin-ase)
Oncaspar ■ Erwinaze
Antineoplastic (miscellaneous) Enzyme
pH 7.3 (Oncaspar)

USUAL DOSE (International units [IU])

Pretreatment:

Baseline studies indicated; see Monitor. Verify pregnancy status.

Oncaspar:

Patients up to and including 21 years of age:

2,500 international units (IU)/M² as an infusion. Do not administer more frequently than every 14 days. Used as a component of a multiple-agent regimen.

Patients over 21 years of age:

2,000 international units (IU)/M^2 as an infusion. Do not administer more frequently than every 14 days. Used as a component of a multiple-agent regimen.

Erwinaze:

To substitute for a dose of pegaspargase:

25,000 international units (IU)/M^2 3 times a week (Monday/Wednesday/Friday) for 6 doses.

To substitute for a dose of native Escherichia coli asparaginase:

25,000 international units (IU)/M^2 for each scheduled dose of native *E. coli* asparaginase within a treatment.

Both products:

May be administered IV or IM; see prescribing information for IM specifics.

DOSE ADJUSTMENTS

Oncaspar:

Monitor patients at least weekly with bilirubin, transaminases, glucose, and clinical exam until recovery from the cycle of therapy. If an adverse reaction occurs, modify treatment according to the following chart.

Dose Modifications for Oncaspar Based on Observed Adverse Reaction

Adverse Reaction	Severity[a]	Action
Infusion reaction/hypersensitivity reaction	Grade 1	Reduce the infusion rate by 50%.
	Grade 2	Interrupt the infusion of Oncaspar. Treat the symptoms. When symptoms resolve, resume the infusion and reduce the infusion rate by 50%.
	Grade 3 to 4	Discontinue Oncaspar permanently.
Hemorrhage	Grade 3 to 4	Hold Oncaspar. Evaluate for coagulopathy and consider clotting factor replacement as needed. Resume Oncaspar with the next scheduled dose if bleeding is controlled.
Pancreatitis	Grade 3 to 4	Hold Oncaspar for elevations in lipase or amylase >3 × ULN until enzyme levels stabilize or are declining. Discontinue Oncaspar permanently if clinical pancreatitis is confirmed.
Thromboembolism	Uncomplicated deep vein thrombosis	Hold Oncaspar. Treat with appropriate antithrombotic therapy. Upon resolution of symptoms, consider resuming Oncaspar while continuing antithrombotic therapy.
	Severe or life-threatening thrombosis	Discontinue Oncaspar permanently. Treat with appropriate antithrombotic therapy.
Hepatotoxicity	Total bilirubin >3 to ≤10 × ULN	Hold Oncaspar until total bilirubin is ≤1.5 × ULN
	Total bilirubin >10 × ULN	Discontinue Oncaspar and do not make up for missed doses.

[a] Grade 1 is mild, Grade 2 is moderate, Grade 3 is severe, and Grade 4 is life-threatening.

Erwinaze:

Dose adjustment recommendations are not provided by the manufacturer. Other sources recommend possible dose adjustment based on patient response and toxicity; see literature.

DILUTION (International units [IU])

Oncaspar:

Available preservative free in 5-mL vials containing 750 IU/mL. Must be further diluted with 100 mL of NS or D5W and administered through the Y-tube or three-way stopcock of a free-flowing infusion of similar solutions (NS or D5W). Do not shake; mix gently. Use only clear solutions.

Erwinaze:

Available as a lyophilized powder in 3-mL vials containing 10,000 IU. Reconstitute each vial by slowly injecting 1 or 2 mL of preservative-free NS against the inner vial wall. Do not inject directly onto or into the powder. 1 mL of diluent yields a concentration of 10,000 IU/mL; 2 mL of diluent yields a concentration of 5,000 IU/mL. Gently mix or swirl; ***do not shake or invert vial***. A clear, colorless solution. Calculate the required dose and volume required and withdraw into a polypropylene syringe within 15 minutes of reconstitution. Slowly inject the calculated dose into a 100-mL IV infusion bag of NS that has been acclimatized to RT. ***Do not shake or squeeze the infusion bag.***

Storage:

Both products: Refrigerate unopened vials, protect from light, and do not use after expiration date on vial. For single-dose use only. Do not re-enter vial; discard unused portions. ***Oncaspar: Do not administer*** if drug has been frozen, stored at RT for more than 48 hours, or shaken or vigorously agitated. Immediate use preferred, but the diluted solution may be refrigerated. Storage after dilution should not exceed 48 hours from the time of preparation to completion of administration. Protect infusion bag from direct sunlight. Discard if cloudy or discolored.

Erwinaze:

Do not freeze or refrigerate after reconstitution and dilution, and administer within 4 hours or discard.

COMPATIBILITY

Both products:

Manufacturer states, “Do not infuse other IV drugs through the same IV line.”

RATE OF ADMINISTRATION

Both products:

A single dose evenly distributed over 1 to 2 hours.

ACTIONS

Oncaspar is L-asparaginase (L-asparagine amidohydrolase) that is covalently conjugated to monomethoxpolyethylene glycol (MPEG). It is a modified form of *E. coli*–derived asparaginase that has a longer half-life than the native enzyme and is less immunogenic. ***Erwinaze*** contains an asparagine-specific enzyme derived from *Erwinia chrysanthemi*. Asparaginase is cycle specific for the G1 phase of the cell cycle. It breaks down asparagine, rapidly depleting it from cells. Some malignant cells have a metabolic defect that makes them unable to synthesize asparagine as normal cells do. They are dependent on exogenous asparagine for survival. Depletion of asparagine kills the leukemic cells without affecting normal cells that synthesize their own asparagine. Plasma half-life of ***Oncaspar*** is approximately 5.8 days after IM administration and approximately 5.3 days after IV administration. Mean half-life of ***Erwinaze*** after IV administration is approximately 7.51 hours. Half-lives are longer when administered IM.

INDICATIONS AND USES

Oncaspar:

First-line treatment of pediatric and adult patients with acute lymphoblastic leukemia (ALL). ■ Treatment of pediatric and adult patients with ALL and hypersensitivity to native forms of L-asparaginase. Used as a component of a multiagent regimen for both indications.

Erwinaze:

A component of a multiagent chemotherapeutic regimen for the treatment of patients with ALL who have developed hypersensitivity to *E. coli*-derived asparaginase.

CONTRAINDICATIONS

Both products:

History of serious thrombosis or serious hemorrhagic events associated with prior L-asparaginase therapy. ■ History of serious hypersensitivity reactions to either product.

Oncaspar:

History of pancreatitis, including pancreatitis related to prior L-asparaginase therapy. ■ Severe hepatic impairment.

Erwinaze:

History of ***serious*** pancreatitis with prior L-asparaginase therapy.

PRECAUTIONS

Both products:

Products are not interchangeable. Ensure correct formulation, route of administration, and dose before administration. ■ Administered by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Serious hypersensitivity reactions can occur. Risk increased in patients with known hypersensitivity to other forms of L-asparaginase. ■ Serious thrombotic events, including sagittal sinus thrombosis and pulmonary embolism (PE), have occurred. ■ Pancreatitis, including hemorrhagic or necrotizing pancreatitis with fatal outcomes, has been reported. ■ Glucose intolerance has occurred; may be irreversible. ■ As with all therapeutic proteins, there is a potential for immunogenicity. ■ See Monitor, Drug/Lab Interactions, and Antidote.

Oncaspar:

Severe or symptomatic coagulopathy with hemorrhage can occur. Increased PT, PTT, or hypofibrinogenemia is possible. ■ Hepatotoxicity and abnormal liver function (including elevations of AST, ALT, alkaline phosphatase, and bilirubin [direct and indirect]) and reduced serum albumin and plasma fibrinogen can occur.

Erwinaze:

Fibrinogen, protein C activity, protein S activity, and anti-thrombin III decreased in a majority of patients after a 2-week course of Erwinaze by IM administration.

Monitor:

Both products: Obtain baseline CBC with differential, coagulation parameters (e.g., fibrinogen, PT, PTT), liver function tests, amylase, lipase, triglycerides, and serum glucose and monitor periodically during treatment. ■ Monitor for S/S of hemorrhage or thrombosis. ■ Evaluate patients with abdominal pain for evidence of pancreatitis. ■ Monitor for S/S of hypersensitivity reactions (e.g., angioedema, bronchospasm, dyspnea, hypotension, laryngeal edema, lip swelling, eye swelling, local erythema or swelling, pruritus, systemic rash, urticaria). ***Oncaspar*** manufacturer recommends observing patient carefully during and for at least 1 hour after infusion. ***Erwinaze:*** With IV use, consider monitoring nadir (predose) serum asparaginase activity (NSAA) levels and switching to IM administration if desired NSAA levels are not achieved.

Patient Education:

Both products: Avoid pregnancy. Females of reproductive potential should use effective contraceptive methods, including a barrier method, during treatment and for at least 3 months after the last dose. Since there is a potential for an indirect interaction between these products and oral contraceptives, the concomitant use of these products and oral contraceptives is not recommended. Another, nonoral contraceptive method should be used in women of childbearing potential. ■ Report all side effects promptly, especially abdominal pain, hypersensitivity reactions (e.g., dizziness, feeling faint, flushing, hives, itching, nausea, pruritus, rash, shortness of breath), bleeding, bruising, increased thirst or urination, or S/S of thrombosis (arm or leg swelling, chest pain, headache, shortness of breath). **Oncaspar:** Promptly report S/S of hepatotoxicity (e.g., bleeding, bruising, jaundice, severe nausea and vomiting). ■ See Appendix D.

Maternal/Child:

Effect on fetus unknown. Based on animal studies, both products can cause fetal harm when administered to a pregnant woman. Use during pregnancy only if clearly needed. ■ Breast-feeding is not recommended during treatment and for 3 months after the last dose. ■ Safety and effectiveness for use in pediatric patients were established with clinical studies.

Elderly:

Oncaspar: Numbers in clinical studies insufficient to determine if the elderly respond differently from younger subjects. ***Erwinaze:*** Safety and effectiveness not studied in geriatric patients.

DRUG/LAB INTERACTIONS

Both products:

Manufacturers state that specific drug interaction studies have not been performed. Other sources suggest the following interactions: Asparaginase may increase the serum concentration of **dexamethasone** (Decadron).

SIDE EFFECTS

Both products:

The most common adverse reactions reported include elevated transaminases, hyperbilirubinemia, hypersensitivity reactions (including anaphylaxis), hyperglycemia, pancreatitis, and thrombosis.

Oncaspar:

Additional commonly reported adverse reactions include abnormal clotting studies, embolic events, febrile neutropenia, hypoalbuminemia. Hyperlipidemia (hypercholesterolemia and hypertriglyceridemia) has also been reported.

Erwinaze:

Additional commonly reported adverse reactions include abdominal pain/discomfort, diarrhea, fever, local reactions, nausea, and vomiting.

Post-Marketing:

Oncaspar:

Hemorrhage (including CNS hemorrhage), hepatic impairment, hyperammonemia, pancreatic cyst.

ANTIDOTE

Both products:

Notify physician of all side effects. Discontinue if coagulopathies or a thrombotic or hemorrhagic event occurs. Symptomatic and supportive treatment is indicated. If the event is mild and symptoms resolve, it may be possible to resume therapy. Administer insulin therapy as necessary in patients with hyperglycemia. Discontinue in patients who experience severe hypersensitivity reactions. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate), and pressor amines (e.g., dopamine). Consider administration of appropriate replacement therapy in patients with severe or symptomatic coagulopathy. There is no specific antidote. ***Oncaspar:*** Discontinue in patients with pancreatitis or serious liver toxicity and provide supportive care as indicated. Reduce, interrupt, or discontinue infusion for an infusion/hypersensitivity reaction as outlined in Dose Adjustments. Hold or discontinue therapy for any given adverse reaction as outlined in Dose Adjustments. ***Erwinaze:*** Discontinue in patients with severe or hemorrhagic pancreatitis manifested by abdominal pain greater than 72 hours and amylase elevation of equal to or greater than 2 times the ULN. In cases of mild pancreatitis, hold therapy until the S/S subside and amylase levels return to normal. After resolution, treatment with Erwinaze may be resumed. Discontinue for a thrombotic or hemorrhagic event until symptoms resolve; after resolution, treatment with Erwinaze may be resumed.

PEGLOTICASE BBW

(peg-**LOE**-ti-kase)
Krystexxa
Antigout agent

USUAL DOSE

Pretreatment:

Discontinue oral urate-lowering medications before beginning therapy; see Precautions and Drug/Lab Interactions. Screening for G6PD deficiency may be indicated and baseline studies indicated; see Monitor.

Gout flare prophylaxis:

Use of an NSAID or oral colchicine is recommended beginning at least 1 week before the start of pegloticase therapy and lasting at least 6 months unless medically contraindicated or not tolerated.

Premedication:

Patients should be premedicated before each dose with antihistamines and corticosteroids to reduce the risk of infusion reactions, including anaphylaxis or other hypersensitivity reactions.

Pegloticase:

8 mg as an IV infusion every 2 weeks. Optimum treatment duration not established.

DOSE ADJUSTMENTS

No dose adjustment is required based on age, gender, race, or renal impairment.

DILUTION

Withdraw 1 mL (8 mg) from the 2-mL vial. A clear, colorless solution that must be further diluted by injecting it into a 250-mL bag of NS or ½NS for infusion. Ensure thorough mixing by inverting the infusion bag a number of times. Do not shake. If diluted solution has been refrigerated, bring to RT before administration (do not subject to artificial heating [e.g., hot water, microwave]).

Filters:

No study data available; if filtering is necessary, contact manufacturer.

Storage:

Before use, refrigerate in carton at 2° to 8° C (36° to 46° F). Protect from light. Do not shake or freeze. Do not use beyond the expiration date stamped. Diluted infusion bags are stable for 4 hours refrigerated or at RT (20° to 25° C [68° to 77° F]). Manufacturer recommends storing under refrigeration (not frozen), protected from light, and used within 4 hours of dilution. Discard unused product remaining in the 2-mL vial.

COMPATIBILITY

Manufacturer states, “Do not mix or dilute with other drugs.”

RATE OF ADMINISTRATION

A single dose properly diluted as an infusion over no less than 2 hours. Do not administer by IV push or as a bolus. Administer by gravity feed, with a syringe-type pump or infusion pump. If an infusion reaction occurs, the infusion may be slowed, or stopped and restarted at a slower rate, at the discretion of the physician.

ACTIONS

A uric acid–specific enzyme; a PEGylated product that consists of recombinant modified mammalian urate oxidase (uricase) produced by a genetically modified strain of *Escherichia coli*. Achieves its therapeutic effect by catalyzing the oxidation of uric acid to allantoin, thereby lowering serum uric acid. Duration of suppression of plasma uric acid appears to be dose related. Allantoin is an inert and water-soluble purine metabolite that is readily eliminated, primarily by renal excretion.

INDICATIONS AND USES

Treatment of chronic gout in adult patients refractory to conventional therapy. Gout refractory to conventional therapy occurs in patients who have failed to normalize serum uric acid and in patients whose S/S are inadequately controlled with xanthine oxidase inhibitors (e.g., allopurinol) at the maximum medically appropriate dose or for whom these drugs are contraindicated.

Limitation of use:

Not recommended for the treatment of asymptomatic hyperuricemia.

CONTRAINDICATIONS

Patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency.

PRECAUTIONS

Administer under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Anaphylaxis and infusion reactions have been reported to occur during and after administration of pegloticase. ■ Anaphylaxis may occur with any infusion, including a first infusion, and generally manifests within 2 hours of the infusion. However, delayed-type hypersensitivity reactions have also been reported. ■ Infusion reactions and anaphylaxis occurred in patients premedicated with one or more doses of an oral antihistamine and an IV corticosteroid and/or acetaminophen. ■ Risk of infusion reaction and anaphylaxis is higher in patients who have lost therapeutic response (e.g., uric acid levels increase to above 6 mg/dL); see Monitor. ■ Concomitant use of oral urate-lowering agents (e.g., allopurinol, febuxostat) and pegloticase may blunt the rise of serum uric acid levels. Discontinue oral urate-lowering medications and do not institute oral urate-lowering agents while taking pegloticase. ■ Life-threatening hemolysis and methemoglobinemia have been reported with pegloticase in patients with G6PD deficiency. ■ An increase in gout flares is often observed with the initiation of anti-hyperuricemic therapy because changing serum uric acid levels result in the mobilization of urate from tissue deposits. Gout flare prophylaxis with an NSAID or colchicine is recommended. Pegloticase does not need to be discontinued because of a gout flare. ■ Exacerbation of CHF has occurred; use with caution in patients with CHF. ■ Data not available for safety and efficacy of retreatment with pegloticase after stopping treatment for longer than 4 weeks. Due to immunogenicity, may increase risk of infusion reactions, including anaphylaxis. ■ Anti-pegloticase antibodies developed in most patients treated. High titers were associated with a failure to maintain pegloticase-induced normalization of uric acid. These patients also had a higher incidence of infusion reactions. Anti-PEG antibodies were also detected; the impact on patients' responses to other PEG-containing therapeutics is unknown. ■ Effects of either renal or hepatic impairment on pegloticase pharmacokinetics were not studied.

Monitor:

Before initiating treatment, screening for G6PD deficiency is recommended in patients at higher risk (e.g., African or Mediterranean [including Southern European and Middle Eastern] and Southern Asian ancestry); see Contraindications. ■ Monitor serum uric acid levels before each infusion. Consider discontinuing treatment if levels increase to above 6 mg/dL, particularly when two consecutive levels above 6 mg/dL are observed. ■ Closely monitor for S/S of potential anaphylaxis for an appropriate period (e.g., during and for at least 1 hour after administration). Manifestations of anaphylaxis have included hemodynamic instability, perioral or lingual edema, and wheezing with or without rash or urticaria. S/S of infusion reactions have included chest discomfort or pain, dyspnea, erythema, flushing, pruritus, and urticaria. S/S of infusion reactions may overlap with those of anaphylaxis. Infusion reactions can occur at any time during therapy, with approximately 3% occurring with the first infusion and approximately 91% occurring during the time of infusion. Slow or stop the infusion (depending on the severity) if an infusion reaction occurs. ■ Closely monitor patients with a history of CHF during and after infusion. ■ Patients being restarted on therapy after a drug-free interval longer than 4 weeks should be monitored carefully.

Patient Education:

Immediately report S/S of an infusion or hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, perioral or lingual edema, pruritus, rash, rigors, urticaria, wheezing). ■ Review prescription and nonprescription drugs with physician. Discontinue use of any oral urate-lowering agents. ■ Report side effects of pegloticase that are bothersome or do not go away (e.g., nausea, vomiting). ■ Patients of African or Mediterranean (including Southern European and Middle Eastern) and Southern Asian descent may require testing for G6PD deficiency. ■ Gout flares may increase with initiation of pegloticase; prophylactic medications recommended.

Maternal/Child:

Use during pregnancy only if clearly needed. ■ Not recommended for use during breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly:

Response similar to other age-groups; however, greater sensitivity in the elderly cannot be ruled out.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Concomitant use of oral **urate-lowering agents** (allopurinol, febuxostat) and pegloticase may blunt the rise of serum uric acid levels; discontinue oral urate-lowering medications and do not institute oral urate-lowering agents while taking pegloticase.

SIDE EFFECTS

The most common side effects include anaphylaxis, chest pain, constipation, contusion or ecchymosis, gout flares, infusion reactions, nasopharyngitis, nausea, pain, and vomiting. The most serious reactions are anaphylaxis, infusion reactions, and gout flares.

Post-Marketing:

Asthenia, malaise, peripheral swelling.

ANTIDOTE

Keep physician informed of all side effects. Some will be tolerated or treated symptomatically. Discontinue immediately for any acute serious infusion or hypersensitivity reaction and treat as appropriate; may require epinephrine, airway management, oxygen, antihistamines, vasopressors, corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary. Slow or stop the infusion (depending on the severity) if an infusion reaction occurs. May be restarted at a slower rate if symptoms subside. Pegloticase does not need to be discontinued because of a gout flare. No specific antidote; monitor and support as indicated in overdose. Resuscitate as necessary.

PEMBROLIZUMAB

(**PEM**-broe-**LIZ**-ue-mab)
Keytruda
Antineoplastic
Monoclonal antibody
pH 5.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Pretesting required and baseline studies indicated; see Monitor.

Patient selection for treatment:

Select patients for treatment with pembrolizumab as a single agent based on the presence of positive PD-L1 expression in:

- Stage III NSCLC who are not candidates for surgical resection or definitive chemoradiation
- Metastatic NSCLC
- First-line treatment of metastatic or unresectable, recurrent head and neck squamous cell carcinoma (HNSCC)
- Metastatic urothelial carcinoma
- Metastatic gastric cancer. If PD-L1 expression is not detected in an archival gastric cancer specimen, evaluate the feasibility of obtaining a tumor biopsy for PD-L1 testing.
- Metastatic esophageal cancer
- Recurrent or metastatic cervical cancer

Information about FDA-approved tests for the detection of PD-L1 expression for these indications is available at http://www.fda.gov/CompanionDiagnostics.

Unresectable or metastatic melanoma:

200 mg administered as an IV infusion over 30 minutes every 3 weeks until disease progression or unacceptable toxicity.

Adjuvant treatment of adult patients with melanoma:

200 mg administered as an IV infusion over 30 minutes every 3 weeks until disease recurrence, unacceptable toxicity, or for up to 12 months in patients without disease recurrence.

Breast cancer, triple negative, high-risk, early stage:

In combination with other chemotherapy for 24 weeks: 200 mg IV once every 3 weeks for 8 doses or 400 mg IV once every 6 weeks for 4 doses, or until disease progression or unacceptable toxicity. Can be given as single agent for up to 27 weeks as 200 mg IV every 3 weeks for 9 doses or 400 mg IV every 6 weeks for 5 doses, until disease progression or unacceptable toxicity.

Metastatic non–small-cell lung cancer (NSCLC), small-cell lung cancer (SCLC), head and neck squamous cell carcinoma (HNSCC), classical Hodgkin lymphoma (cHL), primary mediastinal large B-cell lymphoma (PMBCL), urothelial carcinoma, microsatellite instability–high (MSI-H) cancer, gastric cancer, esophageal cancer, cervical cancer, colorecdtal cancer (unresectable or metastatic); cutaneous squamous cell carcinoma, esophageal cancer, melanoma, hepatocellular carcinoma (HCC), and

Merkel cell carcinoma (MCC):

200 mg administered as an IV infusion over 30 minutes every 3 weeks or 400 mg IV once every 6 weeks until disease progression or unacceptable toxicity or up to 24 months in patients without disease progression. When administering in combination with chemotherapy to patients with NSCLC and HNSCC, pembrolizumab should be administered before chemotherapy when given on the same day. Also see prescribing information for pemetrexed and carboplatin or cisplatin, as appropriate.

High-risk BCG-unresponsive, non–muscle invasive bladder cancer (NMIBC):

200 mg administered as an IV infusion over 30 minutes every 3 weeks until persistent or recurrent high-risk NMIBC, disease progression, or unacceptable toxicity, or up to 24 months in patients without disease progression.

Renal cell carcinoma (RCC):

200 mg administered as an IV infusion over 30 minutes every 3 weeks or 400 mg IV every 6 weeks in combination with 5 mg axitinib orally twice daily until disease progression, unacceptable toxicity or, for pembrolizumab, up to 24 months in patients without disease progression. When axitinib is used in combination with pembrolizumab, dose escalation of axitinib above the initial 5-mg dose may be considered at intervals of 6 weeks or longer. See Prescribing Information for recommended axitinib dosing information.

Endometrial carcinoma:

200 mg administered as an IV infusion over 30 minutes every 3 weeks in combination with lenvatinib 20 mg orally once daily until disease progression, unacceptable toxicity or, for pembrolizumab, up to 24 months in patients without disease progression. See prescribing information for recommended lenvatinib dosing information.

PEDIATRIC DOSE

Classical Hodgkin lymphoma (cHL), primary mediastinal large B-cell lymphoma (PMBCL), microsatellite instability–high (MSI-H) cancer, and Merkel cell carcinoma (MCC):

2 mg/kg (up to a maximum of 200 mg) administered as an IV infusion over 30 minutes every 3 weeks until disease progression or unacceptable toxicity or up to 24 months in patients without disease progression.

DOSE ADJUSTMENTS

No dose reductions are recommended. Withhold or discontinue pembrolizumab to manage adverse reactions as described in the following chart.

Recommended Dose Modifications of Pembrolizumab for Adverse Reactions		
Adverse Reaction	**Severity**[a]	**Dose Modification for Pembrolizumab**
Immune-mediated pneumonitis	Grade 2	Withhold[b]
	Grades 3 or 4 or recurrent Grade 2	Permanently discontinue
Immune-mediated colitis	Grades 2 or 3	Withhold[b]
	Grade 4	Permanently discontinue
Immune-mediated hepatitis in patients with HCC	Aspartate aminotransferase (AST) or alanine aminotransferase (ALT) ≥5 × ULN if baseline less than 2 × ULN; AST or ALT >3 times baseline if baseline ≥2 × ULN Total bilirubin >2 mg/dL if baseline <1.5 mg/dL; or Total bilirubin >3 mg/dL, regardless of baseline levels	Withhold[c]
	ALT or AST >10 × ULN; or Child-Pugh score ≥9 points; Gastrointestinal bleeding suggestive of portal hypertension; or New onset of clinically detectable ascites; or encephalopathy	Permanently discontinue

Immune-mediated hepatitis in patients without HCC	AST or ALT >3 but no more than 5 × ULN or total bilirubin >1.5 but no more than 3 × ULN	Withhold[b]
For liver enzyme elevations in RCC patients treated with combination therapy, see dosing guidelines that follow this chart	In patients without liver metastases, AST or ALT >5 × ULN or total bilirubin >3 × ULN In patients with liver metastasis and Grade 2 AST or ALT at baseline, with an increase in AST or ALT of 50% or more relative to baseline that persists for at least 1 week	Permanently discontinue
Immune-mediated endocrinopathies	Grades 3 or 4	Withhold until clinically stable
Immune-mediated nephritis	Grade 2	Withhold[b]
	Grades 3 or 4	Permanently discontinue
Immune-mediated skin adverse reactions	Grade 3 or suspected Stevens-Johnson Syndrome (SJS) or toxic epidermal necrolysis (TEN)	Withhold
	Grade 4 or confirmed SJS or TEN	Permanently discontinue
Hematologic toxicity in patients with cHL or PMBCL	Grade 4	Withhold until resolution to Grades 0 or 1
Other immune-mediated adverse reactions	Grades 2 or 3 based on the severity and type of reaction	Withhold[b]
	Grade 3 based on the severity and type of reaction or Grade 4	Permanently discontinue
Recurrent immune-mediated adverse reactions	Recurrent Grade 2 pneumonitis Recurrent Grades 3 or 4	Permanently discontinue
Inability to taper corticosteroid	Requirement for 10 mg/day or greater prednisone or equivalent for more than 12 weeks after last dose of pembrolizumab	Permanently discontinue
Persistent Grade 2 or 3 adverse reaction (excluding endocrinopathy)	Grades 2 or 3 adverse reactions lasting 12 weeks or longer after last dose of pembrolizumab	Permanently discontinue
Infusion-related reactions	Grades 1 or 2	Interrupt or slow the rate of infusion
	Grades 3 or 4	Permanently discontinue

[a] Toxicity was graded per National Cancer Institute Common Terminology Criteria for Adverse Events. Version 4.0 (NCI CTCAE v4).

[b] Resume in patients with complete or partial resolution (Grades 0 to 1) after

corticosteroid taper.

[c]Resume in HCC patients when AST or ALT and total bilirubin recover to Grades 0-1 or to baseline.

■ In patients with RCC being treated with pembrolizumab in combination with axitinib: (1) if ALT or AST 3 or more times the ULN but less than 10 times the ULN without concurrent total bilirubin 2 or more times the ULN, withhold both pembrolizumab and axitinib until these adverse reactions recover to Grades 0 to 1. Consider corticosteroid therapy. Consider rechallenge with a single drug or sequential rechallenge with both drugs after recovery. If rechallenging with axitinib, consider dose reduction as per the axitinib prescribing information. Or (2) if ALT or AST 10 or more times the ULN or more than 3 times the ULN with concurrent total bilirubin 2 or more times the ULN, permanently discontinue both pembrolizumab and axitinib and consider corticosteroid therapy. ■ When administering pembrolizumab in combination with lenvatinib for the treatment of endometrial carcinoma, interrupt one or both as appropriate. No dose reductions are recommended for pembrolizumab. Withhold dose, reduce dose, or discontinue lenvatinib in accordance with the instructions in the lenvatinib prescribing information. ■ No dose adjustment is recommended for patients with renal impairment or mild hepatic impairment. In addition, age, gender, race, and tumor burden do not affect the clearance of pembrolizumab. ■ See Precautions, Monitor, and Antidote.

DILUTION

Available in single-use vials containing 100 mg/4 mL (25 mg/mL) of pembrolizumab as a clear to slightly opalescent, colorless to slight yellow solution. Calculate the number of vials required for the recommended dose. Withdraw the required volume from the vial(s) of pembrolizumab and transfer into an IV bag or container of NS or D5W. Mix diluted solution by gentle inversion. ***Do not shake.*** The final concentration of the diluted solution should be between 1 and 10 mg/mL.

Filters:

Must be administered using IV tubing that contains a sterile, nonpyrogenic, low–protein-binding, 0.2- to 5-micron in-line or add-on filter.

Storage:

Before use, refrigerate vials at 2° to 8° C (36° to 46° F) in the carton to protect from light. ***Do not freeze or shake.*** Does not contain a preservative. Store the diluted solutions at RT for no more than 6 hours or refrigerate for no more than 96 hours. Storage times reflect time from initial dilution of solution through administration of dose. If diluted solution is refrigerated, allow it to come to RT before administration. Discard any unused portion left in a vial.

COMPATIBILITY

Manufacturer states, “Do not co-administer other drugs through the same infusion line.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 minutes. If diluted solution for administration has been refrigerated, allow it to come to RT before administration. If a common IV line is used to administer other drugs in addition to pembrolizumab, flush the IV line before and after each infusion of pembrolizumab with NS. Administer through an IV tubing that contains a sterile, nonpyrogenic, low–protein-binding, 0.2- to 5-micron in-line or add-on filter.

ACTIONS

An antineoplastic agent. Pembrolizumab is a humanized monoclonal antibody and an IgG4 kappa immunoglobulin that binds to the programmed death receptor-1 (PD-1 receptor) found on the T-cells. The PD-1 ligands PD-L1 and PD-L2 normally bind to the PD receptor and inhibit T-cell proliferation and cytokine release. Up-regulation of PD-1 ligands occurs in some tumors, and signaling through this pathway can contribute to the inhibition of active T-cell immune surveillance of tumors. Pembrolizumab binds to the PD-1 receptor and blocks its interaction with PD-L1 and PD-L2, releasing PD-1 pathway–mediated inhibition of the immune response, including the antitumor immune response. In syngeneic mouse tumor models, blocking PD-1 activity resulted in decreased tumor growth. Mean elimination half-life is 22 days. Steady-state concentrations were reached by 16 weeks of repeated dosing.

INDICATIONS AND USES

Treatment of patients with **unresectable or metastatic melanoma**. ■ Adjuvant treatment of **melanoma with involvement of lymph node(s)** following complete resection. ■ In combination with pemetrexed and platinum chemotherapy as first-line treatment of patients with **metastatic nonsquamous non–small-cell lung cancer** (NSCLC) with no epidermal growth factor receptor (EGFR) or anaplastic lymphoma kinase (ALK) genomic tumor aberrations. ■ In combination with carboplatin and either paclitaxel or paclitaxel protein-bound for the **first-line treatment of patients with metastatic squamous NSCLC**. ■ As a single agent for first-line treatment of patients with **NSCLC expressing PD-L1** (Tumor Proportion Score [TPS] ≥1%) as determined by an FDA-approved test, with no EGFR or ALK genomic tumor aberrations and either (1) stage III in which patients are not candidates for surgical resection or definitive chemoradiation, or (2) metastatic. ■ As a single agent for the treatment of patients with **metastatic NSCLC** whose tumors express PD-L1 (TPS ≥1%) as determined by an FDA-approved test with disease progression on or after platinum-containing chemotherapy. Patients with EGFR or ALK genomic tumor aberrations should have disease progression on FDA-approved therapy for these aberrations before receiving pembrolizumab. ■ Treatment of patients with **metastatic small-cell lung cancer** (SCLC) with disease progression on or after platinum-based chemotherapy and at least one other prior line of therapy.[a] ■ In combination with platinum and fluorouracil (FU), indicated for the first-line treatment of patients with **metastatic or unresectable, recurrent head and neck squamous cell carcinoma** (HNSCC). ■ As a single agent for the first-line treatment of patients with **metastatic or unresectable, recurrent HNSCC whose tumors express PD-L1** (Combined

Positive Score [CPS] ≥1) as determined by an FDA-approved test. ■ As a single agent for the treatment of patients with **recurrent or metastatic HNSCC** with disease progression on or after platinum-containing chemotherapy. ■ Treatment of adult and pediatric patients with **refractory classical Hodgkin lymphoma** (cHL) or patients who have relapsed after 3 or more prior lines of therapy.[a] ■ Treatment of adult and pediatric patients who have **refractory primary mediastinal large B-cell lymphoma** (PMBCL) or who have relapsed after 2 or more prior lines of therapy[a]; see Limitation of Use. ■ Treatment of patients with **locally advanced or metastatic urothelial carcinoma** who are not eligible for cisplatin-containing chemotherapy and whose tumors express PD-L1 [Combined Positive Score (CPS) ≥10], or in patients who are not eligible for any platinum-containing chemotherapy regardless of PD-L1 status.[a] ■ Treatment of patients with **locally advanced or metastatic urothelial carcinoma** who have disease progression during or after platinum-containing chemotherapy or within 12 months of neoadjuvant or adjuvant treatment with platinum-containing chemotherapy. ■ Treatment of patients with ***Bacillus*** Calmette-Guérin (BCG)-unresponsive, high-risk, non–muscle invasive bladder cancer (NMIBC) with carcinoma in situ (CIS) with or without papillary tumors who are ineligible for or have elected not to undergo cystectomy. ■ Treatment of adult and pediatric patients with **unresectable or metastatic, microsatellite instability–high (MSI-H) or mismatch repair–deficient** (1) solid tumors that have progressed after prior treatment and who have no satisfactory alternative treatment options, or (2) colorectal cancer that has progressed after treatment with fluoropyrimidine, oxaliplatin, and irinotecan[a]; see Limitation of Use. ■ Treatment of patients with **recurrent locally advanced or metastatic gastric or gastroesophageal junction adenocarcinoma whose tumors express PD-L1** (CPS ≥1) as determined by an FDA-approved test, with disease progression on or after two or more prior lines of therapy, including fluoropyrimidine- and platinum-containing chemotherapy and, if appropriate, HER2/neu-targeted therapy.[a] ■ Treatment of patients with **recurrent locally advanced or metastatic squamous cell carcinoma of the esophagus whose tumors express PD-L1** (CPS ≥10) as determined by an FDA-approved test, with disease progression after one or more prior lines of systemic therapy. ■ Treatment of patients with **recurrent or metastatic cervical cancer** with disease progression on or after chemotherapy whose tumors express PD-L1 (CPS ≥1) as determined by an FDA-approved test.[a] ■ Treatment of patients with **hepatocellular carcinoma** (HCC) who have been previously treated with sorafenib.[a] ■ Treatment of adult and pediatric patients with **recurrent locally advanced or metastatic Merkel cell carcinoma** (MCC).[a] ■ In combination with axitinib for the first-line treatment of patients with **advanced renal cell carcinoma** (RCC). ■ In combination with lenvatinib for the treatment of patients with **advanced endometrial carcinoma that is not MSI-H or dMMR** who have disease progression after prior systemic therapy and are not candidates for curative surgery or radiation.[a]

Limitations of use:

Pembrolizumab is not recommended for treatment of patients with PMBCL who require urgent cytoreductive therapy. ■ Other indications come out often, refer to primary literature of on-line drug references for up to date list of indications. ■ The safety and effectiveness in pediatric patients with MSI-H central nervous system cancers have not been established.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Immune-mediated pneumonitis, including fatal cases, has occurred with pembrolizumab. Pneumonitis occurred more frequently in patients with a prior history of thoracic irradiation. ■ Immune-mediated colitis has occurred with pembrolizumab. ■ Immune-mediated hepatitis has occurred with pembrolizumab. ■ Hepatic toxicity has occurred with pembrolizumab in combination with axitinib. ■ Immune-mediated endocrinopathies, including hypophysitis (inflammation of the pituitary gland), thyroid disorders, and type 1 diabetes mellitus (including diabetic ketoacidosis), have occurred with pembrolizumab. ■ Immune-mediated nephritis has occurred with pembrolizumab. ■ Immune-mediated skin adverse reactions, including SJS, TEN (some fatal), exfoliative dermatitis, and bullous pemphigoid have occurred. ■ Numerous other immune-mediated adverse reactions were reported in fewer than 1% of patients. These immune-mediated reactions may involve any organ system and may occur during or after discontinuation of treatment. ■ Solid organ transplant rejection has been reported in patients treated with pembrolizumab. Consider benefit of treatment with pembrolizumab versus the risk of possible organ rejection in these patients. ■ Severe and life-threatening infusion-related reactions, including hypersensitivity and anaphylaxis, have been reported. ■ Immune-mediated complications, including fatal events, have occurred in patients who underwent allogeneic hematopoietic stem cell transplantation (HSCT) after treatment with pembrolizumab. Graft-versus-host disease (GVHD), hyperacute GVHD, and severe hepatic veno-occlusive disease (VOD) have been reported. ■ See Dose Adjustments and Monitor for required dose adjustments, indicated criteria and medications for treatment of adverse reactions, and criteria for discontinuation of pembrolizumab. ■ Pembrolizumab has not been studied in patients with moderate or severe hepatic impairment. ■ A protein substance; has a potential for immunogenicity. ■ See Drug/Lab Interactions.

Monitor:

Obtain serum electrolytes and glucose, baseline liver function tests (e.g., ALT, AST, alkaline phosphatase, total bilirubin), serum creatinine, and thyroid function tests before initiating treatment, and monitor periodically during treatment and as indicated based on clinical evaluation. ■ Consider more frequent monitoring of liver enzymes in patients taking pembrolizumab in combination with axitinib. ■ Monitor for S/S of infusion-related reactions (e.g., chills, fever, flushing, hypotension, hypoxemia, pruritus, rash, rigors, and wheezing); see Dose Adjustments. ■ Monitor patients for S/S of pneumonitis (e.g., chest pain, new or worsening cough, or shortness of breath). Evaluate patients with suspected pneumonitis with radiographic imaging, and administer corticosteroids (initial dose of 1 to 2 mg/kg/day prednisone or equivalent, followed by a taper) for Grade 2 or greater pneumonitis. Withhold pembrolizumab for moderate

(Grade 2) pneumonitis; see Dose Adjustments. ■ Monitor patients for S/S of colitis. Administer corticosteroids (initial dose of 1 to 2 mg/kg/day prednisone or equivalent, followed by a taper) for Grade 2 or greater colitis. Withhold pembrolizumab for moderate (Grade 2) or severe (Grade 3) colitis; see Dose Adjustments. ■ Monitor patients for changes in liver function and S/S of hepatitis (e.g., easy bruising or bleeding, jaundice, lethargy, pain on right side of the abdomen, severe nausea or vomiting). Administer corticosteroids (initial dose of 0.5 to 1 mg/kg/day [for Grade 2 hepatitis] or 1 to 2 mg/kg/day [for Grade 3 or greater hepatitis] prednisone or equivalent, followed by a taper) and, based on severity of liver enzyme elevations, withhold or discontinue pembrolizumab and axitinib if used in combination; see Dose Adjustments. ■ Monitor for S/S of hypophysitis, including hypopituitarism and adrenal insufficiency (e.g., fatigue, headache, dizziness or fainting, changes in vision, low levels of the hormones produced by the pituitary [adrenocorticotropic hormone (ACTH), thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), luteinizing hormone (LH), growth hormone (GH), prolactin]). Administer corticosteroids and hormone replacement as clinically indicated. Withhold pembrolizumab for moderate (Grade 2) hypophysitis, and withhold or discontinue pembrolizumab for severe (Grade 3) or life-threatening (Grade 4) hypophysitis; see Dose Adjustments. ■ Thyroid disorders (hypothyroidism, hyperthyroidism, thyroiditis) can occur at any time during treatment. Monitor patients for changes in thyroid function. Administer replacement hormones for hypothyroidism, and manage hyperthyroidism with thionamides and beta-blockers as appropriate. Withhold or discontinue pembrolizumab for severe (Grade 3) or life-threatening (Grade 4) hyperthyroidism; see Dose Adjustments. ■ Monitor for hyperglycemia or other S/S of diabetes (e.g., increased thirst, urination). Administer insulin for type 1 diabetes, and withhold pembrolizumab and administer antihyperglycemics in patients with severe hyperglycemia; see Dose Adjustments. ■ Monitor patients for changes in renal function. Administer corticosteroids (initial dose of 1 to 2 mg/kg/day prednisone or equivalent, followed by a taper) for Grade 2 or greater nephritis. Withhold pembrolizumab for moderate (Grade 2) nephritis; see Dose Adjustments. ■ Monitor patients for suspected severe skin reactions and exclude other causes. Based on the severity of the adverse reaction, withhold or permanently discontinue and administer corticosteroids. Withhold pembrolizumab for Grade 3 skin reactions or suspected Stevens-Johnson syndrome (SJS) or toxic epidermal necrolysis (TEN). If SJS or TEN is suspected, refer the patient for specialized care for assessment and treatment. Permanently discontinue pembrolizumab for Grade 4 skin reactions or confirmed SJS or TEN. ■ Monitor patient for other clinically significant immune-mediated adverse reactions. Examples of immune-mediated adverse reactions that have occurred include arthritis, encephalitis, Guillain-Barré syndrome, hemolytic anemia, myasthenia gravis, myelitis, myocarditis, myositis, pancreatitis, sarcoidosis, uveitis, and vasculitis. ■ For any suspected immune-mediated adverse reactions, ensure adequate evaluation to confirm etiology or to exclude other causes. Based on the severity of the adverse reaction, withhold pembrolizumab and administer corticosteroids. With improvement to Grade 1 or less, begin corticosteroid taper and continue to taper over at least 1 month. Based on limited data from clinical trials in patients whose immune-related adverse reactions could not be controlled with corticosteroids, administration of other systemic immunosuppressants can be considered. Restart pembrolizumab if the adverse reaction remains at Grade 1 or less following taper; see Dose Adjustments. ■ Monitor patients who have undergone allogeneic HSCT after pembrolizumab for transplant-related complications such as hyperacute GVHD, severe acute GVHD, hepatic VOD, steroid-requiring febrile syndrome, and other immune-mediated adverse reactions. Prompt intervention required.

Patient Education:

Review manufacturer's medication guide. ■ Highly effective contraception required during treatment with pembrolizumab and for at least 4 months following the last dose of pembrolizumab. ■ Promptly report a known or suspected pregnancy. ■ Immediately report any S/S of infusion-related reactions (e.g., chills, fever, flushing, hypotension, hypoxemia, pruritus, rigors, and wheezing). ■ Some side effects may require corticosteroid treatment and interruption or discontinuation of pembrolizumab. ■ Promptly report S/S of pneumonitis (e.g., chest pain, new or worsening cough, or shortness of breath). ■ Promptly report S/S of colitis (e.g., diarrhea or severe abdominal pain). ■ Promptly report S/S of hepatitis (e.g., easy bruising or bleeding, jaundice, lethargy, pain on right side of the abdomen, severe nausea or vomiting). ■ Promptly report S/S of hypophysitis (e.g., dizziness or fainting, extreme weakness, persistent or unusual headache, vision changes) or of hypothyroidism, hyperthyroidism, or type 1 diabetes mellitus (e.g., constipation, dizziness or fainting, extreme tiredness, feeling cold, hair loss, headaches that will not go away, increased thirst or urination, weight gain or loss). ■ Promptly report any S/S of severe skin reactions, SJS, or TEN. ■ Contact health care provider immediately for S/S of organ transplant rejection. ■ Inform patient about the risk for postallogeneic hematopoietic stem cell transplantation complications. ■ Promptly report S/S of kidney dysfunction (e.g., blood in urine, decreased urine output, loss of appetite, swelling in ankles). ■ Keeping scheduled appointments for blood work or other laboratory tests is imperative.

Maternal/Child:

Has the potential to be transmitted from the mother to the developing fetus. Based on its mechanism of action and data from animal studies, pembrolizumab can cause fetal harm when administered to a pregnant woman; see Patient Education. ■ Discontinue breast-feeding during treatment and for 4 months after the final dose. ■ There is limited experience in pediatric patients. The concentrations of pembrolizumab in pediatric patients were comparable to those observed in adult patients at the same dose regimen of 2 mg/kg every 3 weeks. Abdominal pain, fatigue, hypertransaminasemia, hyponatremia, and vomiting occurred at a higher rate in pediatric patients when compared with adults under 65 years of age. Safety and effectiveness for use in pediatric patients with cHL, PMBCL, and MSI-H cancer have been established. Safety and effectiveness have not been established in other approved indications.

Elderly:

No overall differences in safety or efficacy were reported between elderly patients and younger adults.

DRUG/LAB INTERACTIONS

No formal pharmacokinetic drug interaction studies have been conducted with pembrolizumab. ■ In patients with multiple myeloma, the addition of pembrolizumab to a thalidomide analog plus dexamethasone resulted in increased mortality. This specific therapy is not indicated and is not recommended for use outside of controlled clinical trials.

SIDE EFFECTS

Pembrolizumab as a single agent:

The most common adverse reactions (reported in at least 20% of patients) were abdominal pain, constipation, cough, decreased appetite, diarrhea, dyspnea, fatigue, fever, musculoskeletal pain, nausea, pain, pruritus, and rash.

Pembrolizumab in combination with pemetrexed and platinum chemotherapy:

The most common adverse reactions (reported in at least 20% of patients) were alopecia, asthenia, constipation, cough, decreased appetite, diarrhea, dyspnea, fatigue, fever, mucosal inflammation, nausea, peripheral neuropathy, rash, stomatitis, and vomiting.

Pembrolizumab in combination with axitinib:

The most common adverse reactions (reported in at least 20% of patients) were asthenia, constipation, cough, decreased appetite, diarrhea, dysphonia, fatigue, hepatoxicity, hypertension, hypothyroidism, mucosal inflammation, nausea, palmar-plantar erythrodysesthesia, rash, and stomatitis.

Pembrolizumab in combination with lenvatinib:

The most common adverse reactions (reported in at least 20% of patients) were abdominal pain, constipation, cough, decreased appetite, decreased weight, diarrhea, dyspnea, dysphonia, fatigue, headache, hemorrhagic events, hypertension, hypomagnesemia, hypothyroidism, musculoskeletal pain, nausea, palmar-plantar erythrodysesthesia, rash, stomatitis, urinary tract infection, and vomiting. Other reported side effects included anemia; arrhythmia; arthralgia; asthenia; back pain; chills; decreased bicarbonate; dizziness; headache; hematuria; hemorrhage; herpes zoster; hypercholesterolemia; hyperglycemia; hyperkalemia; hypertriglyceridemia; hypoalbuminemia; hypocalcemia; hypoglycemia; hypokalemia; hyponatremia; hypophosphatemia; increased alkaline phosphatase, influenza-like illness, ALT, AST, creatinine; insomnia; leukopenia; lymphopenia; myalgia; neck pain; neutropenia; pain in extremity; peripheral edema; peripheral neuropathy; pneumonia; sepsis; thrombocytopenia; upper respiratory tract infection; urinary tract infection; and vitiligo; see Precautions.

Post-Marketing:

Solid organ transplant rejection.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Withhold or discontinue pembrolizumab as outlined in Dose Adjustments. Treat side effects aggressively; see Precautions and Monitor. Treat severe infusion reactions as indicated (e.g., epinephrine, diphenhydramine, IV fluids, oxygen).

PEMETREXED

(peh-meh-**TREX**-ed)
Alimta
Antineoplastic (Antimetabolite)
pH 6.6 to 7.8

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor. See Premedication.

Premedication Required

Regimen to mitigate toxicity begins 1 week before the first infusion of pemetrexed.

Folic acid supplementation:

Prophylaxis to reduce treatment-related hematologic and GI toxicity (pemetrexed is an antifolate; severe myelosuppression can occur); 400 to 1,000 mcg of folic acid ***must*** be taken daily for 7 days ***before*** the first dose of pemetrexed. Must be continued daily throughout treatment regimen and for 21 days after last dose.

Vitamin B_{12} supplementation:

Prophylaxis to reduce treatment-related hematologic and GI toxicity; 1,000 mcg of vitamin B_{12} ***must*** be given as an IM injection 1 week ***before*** the first dose of pemetrexed. Repeat this dose every 3 cycles (about every 9 weeks) during treatment; subsequent doses may be given on the same day as the pemetrexed infusion. ***Do not substitute oral vitamin B_{12} for intramuscular vitamin B_{12}***.

Corticosteroid:

To reduce incidence and severity of dermatologic toxicity, administer dexamethasone 4 mg PO (or equivalent) twice daily the day before, the day of, and the day after the pemetrexed infusion. Repeat with each planned dose of pemetrexed.

Prehydration:

Required with cisplatin; see cisplatin monograph.

Pemetrexed

Malignant pleural mesothelioma:

500 mg/M^2 as an IV infusion over 10 minutes administered before cisplatin on Day 1 of each 21-day cycle until disease progression or unacceptable toxicity.

Nonsquamous non–small-cell lung cancer (NSCLC):

Initial treatment of locally advanced or metastatic NSCLC:

500 mg/M^2 as an IV infusion over 10 minutes administered before cisplatin on Day 1 of each 21-day cycle for up to 6 cycles in the absence of disease progression or unacceptable toxicity.

Maintenance treatment of locally advanced or metastatic NSCLC:

500 mg/M^2 as an IV infusion over 10 minutes on Day 1 of each 21-day cycle until disease progression or unacceptable toxicity. Given after 4 cycles of platinum-based first-line chemotherapy.

Treatment of recurrent/metastatic disease:

500 mg/M^2 as an IV infusion over 10 minutes on Day 1 of each 21-day cycle until disease progression or unacceptable toxicity.

Initial treatment of metastatic NSCLC:

500 mg/M^2 administered as an IV infusion over 10 minutes; administered after pembrolizumab and before carboplatin or cisplatin on Day 1 of each 21-day cycle for 4 cycles. Following completion of platinum-based therapy, pemetrexed may be administered as maintenance therapy, alone or with pembrolizumab, until disease progression or unacceptable toxicity. Pembrolizumab should be administered before pemetrexed when given on the same day.

Refer to the full prescribing information for cisplatin, pembrolizumab, and carboplatin.

DOSE ADJUSTMENTS

Pemetrexed dosing recommendations are provided for patients with a CrCl of 45 mL/min or greater. There is no recommended dose for patients whose CrCl is less than 45 mL/min. ■ Other than those recommended for all patients, no dose adjustments are required based on age, gender, or race or in patients with a CrCl equal to or greater than 45 mL/min. ■ Delay initiation of the next cycle of treatment until the ANC (absolute neutrophil count) is 1,500 cells/mm^3 or higher, the platelet count is 100,000 cells/mm^3 or higher, the CrCl is 45 mL/min or higher and there is recovery of nonhematologic toxicity to Grade 0 to 2. Upon recovery, modify the dosage of pemetrexed in the next cycle as outlined in the following chart.

Pemetrexed Dose Modifications for Adverse Reactions[a]

Toxicity in Most Recent Treatment Cycle	Pemetrexed Dose Modification for Next Cycle
Myelosuppressive Toxicity	
ANC $<500/\text{mm}^3$ **and** platelets $\geq 50,000/\text{mm}^3$ OR Platelet count $<50,000/\text{mm}^3$ without bleeding	75% of previous dose
Platelet count $<50,000/\text{mm}^3$ with bleeding	50% of previous dose
Recurrent Grade 3 or 4 myelosuppression after 2 dose reductions	Discontinue
Nonhematologic Toxicity	
Any Grade 3 or 4 toxicities EXCEPT mucositis or neurologic toxicity OR Diarrhea requiring hospitalization	75% of previous dose
Grade 3 or 4 mucositis	50% of previous dose
Renal toxicity	Withhold until creatinine clearance is 45 mL/min or greater
Grade 3 or 4 neurologic toxicity	Permanently discontinue
Recurrent Grade 3 or 4 nonhematologic toxicity after 2 dose reductions	Permanently discontinue
Severe and life-threatening skin toxicity	Permanently discontinue
Interstitial pneumonitis	Permanently discontinue

[a] National Cancer Institute Common Toxicity Criteria for Adverse Events version 2 (NCI CTCAE v2).

- Refer to prescribing information of agents in combination therapies for indicated dosing modifications.

DILUTION

Specific techniques required; see Precautions. Calculate the dose and number of vials needed. Reconstitute each 100-mg vial with 4.2 mL of preservative-free NS and each 500-mg vial with 20 mL of preservative-free NS. Concentration equals 25 mg/mL. Gently swirl to completely dissolve the powder. Solution ranges in color from colorless to yellow or green-yellow. Withdraw the required volume to provide the calculated dose of pemetrexed. ***Must*** be further diluted to a total volume of 100 mL with preservative-free NS.

Filters:

No data available from manufacturer.

Storage:

Store unopened vials at CRT. Reconstituted and diluted solutions are chemically and physically stable for 24 hours refrigerated. Contains no preservatives; discard unused portions.

COMPATIBILITY

Manufacturer states, “Is physically **incompatible** with diluents containing calcium, including lactated Ringer’s and Ringer’s injection. Co-administration with other diluents has not been studied.” **Compatible** with standard PVC administration sets and bags.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 10 minutes.

ACTIONS

An antifolate antineoplastic agent. It disrupts folate-dependent metabolic processes essential for cell replication. Transported into cells by both the reduced folate carrier and the membrane folate-binding protein transport systems. Converts to polyglutamate forms, which are inhibitors of folate-dependent enzymes involved in the de novo biosynthesis of thymidine and purine nucleotides. 81% bound to plasma protein. Not appreciably metabolized. Half-life is 3.5 hours. Primarily eliminated in urine as an unchanged drug.

INDICATIONS AND USES

Used in combination with cisplatin for the initial treatment of malignant pleural mesothelioma in patients whose disease is unresectable or who are not candidates for curative surgery. ■ Used in combination with cisplatin for the initial treatment of patients with locally advanced or metastatic nonsquamous NSCLC. ■ In combination with platinum chemotherapy and pembrolizumab for the initial treatment of patients with metastatic nonsquamous NSCLC with no EGFR or ALK genomic tumor aberration. ■ As a single agent for maintenance treatment of patients with locally advanced or metastatic nonsquamous NSCLC whose disease has not progressed after 4 cycles of platinum-based first-line chemotherapy. ■ As a single agent for treatment of patients with recurrent, metastatic nonsquamous NSCLC after prior chemotherapy.

Limitation of use:

Not indicated for treatment of squamous cell NSCLC.

CONTRAINDICATIONS

History of severe hypersensitivity reaction to pemetrexed or any of its components. ■ Should not be administered to patients with a CrCl less than 45 mL/min.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Should be administered by or under the direction of a physician specialist in a facility equipped to monitor the patient and respond to any medical emergency. ■ Myelosuppression (e.g., anemia, neutropenia, thrombocytopenia) is a dose-limiting toxicity. May result in requirement for transfusions and development of neutropenic infection; see Dose Adjustments. ■ The risk of myelosuppression is increased in patients who do not receive vitamin supplementation. Folic acid and vitamin B_{12} supplementation are required as a prophylactic measure to reduce treatment-related hematologic and GI toxicity. ■ Pemetrexed can cause severe and sometimes fatal renal toxicity. ■ Serious and sometimes fatal, bullous, blistering, and exfoliative skin toxicity, including cases suggestive of Stevens-Johnson syndrome/toxic epidermal necrolysis, have been reported. ■ Serious interstitial pneumonitis, including fatal cases, can occur. ■ Radiation recall can occur with pemetrexed in patients who have received radiation weeks to years previously. ■ Use caution in patients with a CrCl less than 80 mL/min if ibuprofen (Advil, Motrin) is administered concurrently; see Drug/Lab Interactions. ■ See Dose Adjustments and Contraindications.

Monitor:

Pretreatment with folic acid, vitamin B_{12}, dexamethasone, and adequate hydration required; see Usual Dose. ■ Obtain baseline CrCl and CBC, including platelet count. Repeat CrCl before each dose. Repeat CBC and platelet count on Day 1 before each dose and on Days 8 and 15 of each cycle. Do not begin a new cycle of treatment unless the ANC is equal to or greater than 1,500 cells/mm^3, the platelet count is equal to or greater than 100,000 cells/mm^3, and the CrCl is equal to or greater than 45 mL/min. ■ Monitor for skin toxicity. ■ Monitor for S/S of pneumonitis (e.g., cough, dyspnea, fever). Withhold pemetrexed pending diagnostic evaluation; see Dose Adjustments. ■ Monitor for radiation recall reaction, if indicated. ■ Monitor patients who have been or are taking ibuprofen carefully for signs of toxicity, especially myelosuppression and renal or GI toxicity; see Drug/Lab Interactions. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See Precautions, Drug/Lab Interactions, and Antidote.

Patient Education:

Review manufacturer's patient information guide. ■ Avoid pregnancy; use of effective contraception is recommended for females of reproductive potential during treatment with pemetrexed and for 6 months after the final dose, and for males with partners of reproductive potential during treatment and for 3 months after the final dose. Women should report a suspected pregnancy immediately. ■ May impair male fertility. ■ Adherence to medication regimen (folic acid, vitamin B_{12}, dexamethasone), avoidance or limiting of ibuprofen, and keeping appointments for required lab work and health care provider visits are imperative. ■ Promptly report S/S of anemia, bleeding, cough, decreased urine output, dehydration from diarrhea or vomiting, dyspnea, fatigue, infection (e.g., fever), radiation recall (in patients who have received prior radiation), rash, redness or sores in the mouth, trouble swallowing, or other symptoms. ■ See Appendix D, p. 1311.

Maternal/Child:

Based on animal studies and its mechanism of action, pemetrexed can cause fetal harm; avoid pregnancy. ■ Do not breast-feed during treatment and for 1 week after the last dose of pemetrexed. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

See Dose Adjustments; required only based on general patient criteria. No overall differences in effectiveness were observed between older and younger patients. ■ Incidence of CTCAE Grade 3 and 4 anemia, fatigue, hypertension, neutropenia, and thrombocytopenia was greater in patients 65 years of age or older even though they were fully supplemented with vitamins.

DRUG/LAB INTERACTIONS

Ibuprofen decreases clearance and increases AUC. In patients with a CrCl between 45 and 79 mL/min avoid administration of ibuprofen for 2 days before, the day of, and at least 2 days after a dose of pemetrexed. Monitor for hematologic, renal, and GI toxicity if concomitant use cannot be avoided. ■ Pharmacokinetics of pemetrexed and cisplatin are not affected by each other. ■ Coadministration of oral folic acid or IM vitamin B_{12} does not adversely affect pemetrexed. ■ Is not a clinically significant inhibitor of drugs metabolized by cytochrome P_{450} enzymes. ■ May be used concurrently with aspirin in low to moderate doses (325 mg every 6 hours). Effect of higher doses not known.

SIDE EFFECTS

The most common adverse reactions with single-agent use are anorexia, fatigue, and nausea. When used in combination with cisplatin, the most common adverse reactions include constipation, hematologic toxicity (anemia, leukopenia, lymphopenia, neutropenia, thrombocytopenia), pharyngitis, stomatitis, and vomiting. When used in combination with platinum chemotherapy and pembrolizumab, the most common adverse reactions included asthenia, constipation, cough, decreased appetite, diarrhea, dyspnea, fatigue, fever, nausea, rash, and vomiting. Other side effects, depending on regimen, may include alopecia; arthralgia; chest pain; conjunctivitis; cough; decreased CrCl; dehydration; dizziness; dysgeusia; dyspepsia; dyspnea; edema; elevated alkaline phosphatase, ALT, AST, and creatinine; embolism or thrombosis; fatigue; febrile neutropenia; fever; headache; hyperglycemia; hyperkalemia; hypertension; hypersensitivity reactions; hypertriglyceridemia; hypoalbuminemia; hypocalcemia; hypokalemia; hyponatremia; hypophosphatemia; infection; insomnia; neuropathy (sensory); pruritus; rash/desquamation; renal failure; taste disturbance; and upper respiratory tract infections. Numerous other adverse reactions were reported in fewer than 5% of patients.

Overdose:

Bone marrow suppression (e.g., anemia, neutropenia, thrombocytopenia), diarrhea, infection with or without fever, mucositis, rash.

Post-Marketing:

Colitis, edema, esophagitis, immune-mediated hemolytic anemia, interstitial pneumonitis, pancreatitis, radiation recall, serious and fatal bullous skin conditions, Stevens-Johnson syndrome, and toxic epidermal necrolysis.

ANTIDOTE

Keep physician informed of all side effects. Pemetrexed may be delayed or discontinued based on the degree of side effects; see Dose Adjustments. Symptomatic and supportive therapy is indicated. Death may occur from the progression of some side effects. Based on animal studies, administration of leucovorin may mitigate the toxicities of a pemetrexed overdose. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen, Zarxio], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Effect of hemodialysis on pemetrexed is unknown.

PENICILLIN G AQUEOUS

(pen-ih-**SILL**-in **A**-kwe-us)
Penicillin G Potassium, Penicillin G Sodium, Pfizerpen
Antibacterial (penicillin)
pH 5.5 to 8

USUAL DOSE

Dose dependent on type and severity of infection. See package insert for dosing for specific indications.

Adults and pediatric patients 12 years of age and older:

1 million to 24 million units/24 hr equally distributed over 24 hours as a continuous infusion or equally divided in 4 to 6 intermittent infusions (250,000 to 6 million units every 6 hours or 166,000 to 4,000,000 units every 4 hours). (400,000 units equals approximately 250 mg.)

Meningococcal meningitis and/or septicemia:

Manufacturer recommends a dose of 24 million units/24 hr as 2 million units every 2 hours.

PEDIATRIC DOSE

Administration by intermittent infusion over 15 to 30 minutes is preferred. Dose is based on age or weight and the severity of the infection.

Serious infections (e.g., pneumonia, endocarditis):

25,000 to 50,000 units/kg every 4 hours or 37,500 to 75,000 units/kg every 6 hours (150,000 to 300,000 units/kg/24 hr).

Meningitis:

41,666 units/kg every 4 hours (250,000 units/kg/24 hr). Continue treatment for 7 to 14 days. Maximum dose is 12 to 20 million units/24 hr.

Disseminated gonococcal infections (arthritis), weight less than 45 kg:

25,000 units/kg every 6 hours (100,000 units/kg/24 hr) for 7 to 10 days.

Disseminated gonococcal infections (meningitis), weight less than 45 kg:

41,666 units/kg every 4 hours (250,000 units/kg/24 hr) for 10 to 14 days.

Disseminated gonococcal infections (endocarditis), weight less than 45 kg:

41,666 units/kg every 4 hours (250,000 units/kg/24 hr) for 4 weeks.

Disseminated gonococcal infections (arthritis, meningitis, endocarditis), weight 45 kg or greater:

2,500,000 units every 6 hours (10,000,000 units/24 hr). Duration of therapy is dependent on diagnosis.

Syphilis (congenital or neurosyphilis) after the newborn period:

50,000 units/kg every 4 to 6 hours (200,000 to 300,000 units/kg/24 hr). Continue treatment for 10 to 14 days.

Diphtheria (adjunctive to antitoxin and prevention of carrier state):

37,500 to 62,500 units/kg every 6 hours (150,000 to 250,000 units/kg/24 hr) for 7 to 10 days.

Rat-bite fever, Haverhill fever (caused by a specific organism):

25,000 to 41,666 units/kg every 4 hours (150,000 to 250,000 units/kg/24 hr) for 4 weeks.

The American Association of Pediatrics (AAP) recommends:

Pediatric patients from 1 month to under 12 years of age:

Mild to moderate bacterial infections:

25,000 to 37,500 units/kg every 6 hours (100,000 to 150,000 units/kg/24 hr).

Severe infections:

33,333 to 50,000 units/kg every 4 hours (200,000 to 300,000 units/kg/24 hr).

NEONATAL DOSE

Administration by intermittent infusion over 15 to 30 minutes is preferred. Dose is based on weight and age and the severity of the infection.

The American Academy of Pediatrics (AAP) has recommended 25,000 to 50,000 units/dose. Adjust the dosing intervals based on the neonate’s weight and age as follows:

Moderate to severe bacterial infections:

7 days of age or younger:

Every 12 hours.

8 to 28 days of age:

Every 8 hours.

Higher doses may be required for the treatment of meningitis.

DOSE ADJUSTMENTS

Reduce dose in severe impaired renal function; additional reductions may be indicated if liver function is also impaired. ■ If CrCl is greater than 10 mL/min/1.73 M^2 in uremic patients, give a full loading dose followed by one-half loading dose every 4 to 5 hours. ■ If CrCl is less than 10 mL/min/1.73 M^2, administer a full loading dose followed by one-half of the loading dose every 8 to 10 hours. Another source recommends giving 75% of a normal dose every 4 to 6 hours to patients with a CrCl of 10 to 50 mL/min and 20% to 50% of a normal dose every 4 to 6 hours to patients with a CrCl less than 10 mL/min. ■ Additional dose modifications may be indicated in patients with impaired hepatic and/or renal function. ■ See Drug/Lab Interactions.

DILUTION

Available as a premixed frozen solution, or reconstitute each vial with SWFI or NS. Direct flow of diluent against sides of the vial while gently rotating vial. Shake vigorously. Directions on vial should be followed to provide desired number of units per milliliter. Available with 1, 5, 10, and 20 million units per vial. May be added to NS or dextrose solutions for infusion. See chart on inside back cover.

Storage:

Dry powder stored at CRT. Reconstituted solutions of penicillin G potassium are stable for 1 week if refrigerated. Reconstituted solutions of penicillin G sodium are stable for 3 days if refrigerated. Infusion solutions are stable at CRT for 24 hours. Store premixed frozen solution at or below −20° C (−4° F). The thawed solution is stable for 14 days refrigerated or for 24 hours at RT. Do not refreeze.

COMPATIBILITY

Penicillins are rapidly inactivated in alkaline carbohydrate solutions, reducing agents, alcohols, and glycols; optimum pH range is 6 to 7. To preserve bactericidal action, consult pharmacist before mixing other agents with penicillin in the infusion solution. May form a precipitate with vancomycin. Inactivated in solution with aminoglycosides. Do not mix in the same solution. Appropriate spacing and/or separate sites required. See Drug/Lab Interactions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Penicillin is not given by IV injection. Administer as ordered as continuous IV drip; for example, 5 million units in 1,000 mL of D5W over 12 hours. Is sometimes given by intermittent infusion (⅙ or ¼ of a daily dose in 100 mL over 15 to 30 minutes every 4 to 6 hours). Because of its short half-life, frequent dosing is required to maintain serum concentration above the MIC (minimum inhibitory concentration) for most of the dosing interval. Too-rapid administration or excessive doses may cause electrolyte imbalance and/or seizures. Stable at room temperature for at least 24 hours.

Pediatric rate:

Administration by intermittent infusion over 15 to 30 minutes is preferred for infants and children.

ACTIONS

A natural penicillin, bactericidal against penicillin-sensitive microorganisms during the stage of active multiplication. Inhibits bacterial cell wall synthesis. Distributed into most areas of the body. Distribution into spinal fluid is minimal unless inflammation is present. Half-life is approximately 40 minutes. Crosses the placental barrier. Excreted in the urine via glomerular filtration and tubular secretion. Secreted in breast milk. Available in a potassium salt containing 1.7 mEq of potassium and 1.02 mEq sodium in 1 million units or a sodium salt containing 1.68 mEq sodium in 1 million units.

INDICATIONS AND USES

Serious infections caused by penicillin G–sensitive gram-positive, gram-negative, and anaerobic microorganisms (e.g., empyema, endocarditis, meningitis, pericarditis, pneumonia, septicemia). See manufacturer’s prescribing information for a complete list of clinical indications/infecting organisms. Penicillin G is not the drug of choice in the treatment of gram-negative bacillary infections.

Unlabeled uses:

Group B streptococcus, maternal dose (neonatal prophylaxis).

CONTRAINDICATIONS

Known sensitivity to any penicillin. ■ Premixed solutions containing dextrose may be contraindicated in patients with a known allergy to corn or corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients undergoing penicillin therapy; most likely to occur in patients with a history of penicillin hypersensitivity or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies necessary to determine susceptibility of the causative organism to penicillin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, penicillin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue treatment for 48 to 72 hours after symptoms subside. To reduce the risk of rheumatic fever, patients being treated for Group A beta-hemolytic streptococcal infections should be treated for at least 10 days. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with penicillin. ■ Potassium penicillin most frequently used. Doses over 10,000,000 units may cause fatal hyperkalemia, especially in patients with renal insufficiency.

Monitor:

Periodic evaluation of renal, hepatic, and hematopoietic systems is recommended in prolonged therapy. ■ Monitor for S/S of hypersensitivity reaction. ■ Test patients with gonococcal infections and syphilis for HIV. Test patients with gonococcal infections for syphilis. ■ Electrolyte imbalance from potassium or sodium content is very possible. Monitor closely. Penicillin G potassium contains 1.02 mEq sodium/million units. May aggravate CHF, especially in the elderly. ■ May cause thrombophlebitis; observe carefully and rotate infusion sites. ■ See Drug/Lab Interactions.

Patient Education:

May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Promptly report S/S of a hypersensitivity reaction (e.g., light-headedness, rash, tightness of the chest, urticaria, wheezing).

Maternal/Child:

Category B: use only if clearly needed. ■ Use caution during breast-feeding. May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Elimination rate markedly reduced in neonates.

Elderly:

Response similar to that seen in younger adults. ■ Consider age-related organ impairment and concomitant disease or drug therapy. Monitor renal function. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **aminoglycosides**. Synergism may be inconsistent; see Compatibility. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, sulfonamides, tetracyclines); may interfere with bactericidal action. ■ **ASA, ethacrynic acid, furosemide, indomethacin, sulfonamides, and thiazide diuretics** may interfere with tubular secretion of penicillin, increasing serum concentration and risk of toxicity. ■ Risk of bleeding with **anticoagulants** (e.g., warfarin) may be increased. ■ **Probenecid** decreases elimination of penicillin, resulting in prolonged half-life and increased serum levels. May be desirable or may cause toxicity. ■ May decrease effectiveness of **oral**

contraceptives; breakthrough bleeding or pregnancy could result. ■ Concomitant use with **potassium supplements, potassium-sparing diuretics, or ACE inhibitors** may increase risk of hyperkalemia. ■ May decrease clearance and increase toxicity of **methotrexate.** ■ May cause false values in common **lab tests;** see literature.

SIDE EFFECTS

Acute interstitial nephritis, arthralgia, chills, CDAD, convulsions, edema, fever, hemolytic anemia, hyperkalemia, hyperreflexia, hypersensitivity reactions (immediate [e.g., anaphylaxis, angioneurotic edema, bronchospasm, cardiovascular collapse, hypotension, laryngospasm, death] and delayed [e.g., serum sickness–like symptoms and various skin rashes]), Jarisch-Herxheimer reaction (in patients with syphilis or other spirochetal infections), nausea, neurotoxicity, neutropenia, pain at the injection site, skin rash, sodium-induced congestive heart failure, stomatitis, thrombophlebitis, urticaria, vomiting. Higher-than-normal doses may cause neurologic adverse effects including convulsions, especially with impaired renal function.

ANTIDOTE

For all side effects, discontinue the drug, treat hypersensitivity reactions or resuscitate as necessary, and notify the physician. Treat minor side effects symptomatically according to physician's order. Mild cases of CDAD may respond to discontinuation of the drug. Removed by hemodialysis.

PENTAMIDINE ISETHIONATE

(pen-**TAM**-ih-deen is-ah-**THIGH**-oh-nayt)
Antiprotozoal
pH 4.09 to 5.4

USUAL DOSE

Pretreatment:

Baseline studies required; see Monitor.

Treatment of *Pneumocystis jiroveci:*

4 mg/kg of body weight once daily for 14 days. See Precautions/Monitor. Has been used up to 21 days; benefits not defined.

Pneumocystis prophylaxis:

4 mg/kg once each month. May be given every 2 weeks if indicated.

Leishmania, visceral (unlabeled):

2 to 4 mg/kg once daily for up to 15 days.

Leishmania, cutaneous (unlabeled):

2 to 4 mg/kg once or twice a week until lesions heal.

Trypanosoma gambiense (unlabeled):

4 mg/kg once daily for 10 days.

PEDIATRIC DOSE

Pneumocystis jiroveci:

4 mg/kg once daily for 12 to 14 days.

Pneumocystis prophylaxis:

See Usual Dose.

Leishmania donovani:

2 to 4 mg/kg once daily for 15 days. Up to 21 days have been suggested, but risks with therapy over 14 days may be increased.

Trypanosoma gambiense:

See Usual Dose.

DOSE ADJUSTMENTS

Reduced dose in renal failure may be indicated. One source recommends 4 mg/kg every 24 hours with a CrCl of 10 to 50 mL/min or 4 mg/kg every 24 to 36 hours with a CrCl less than 10 mL/min.

DILUTION

Initially dilute each 300 mg or fraction thereof in 3 to 5 mL SWFI or D5W. A single dose must be further diluted in 50 to 250 mL of D5W and given as an infusion.

Storage:

Stable at room temperature for 24 hours. Discard unused portion. Protect dry product and reconstituted solution from light.

COMPATIBILITY

Will form a precipitate with NS; do not use for dilution or infusion. Manufacturer states, “Do not mix pentamidine solutions with any other drugs.”

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose should be evenly distributed over 60 minutes.

Leishmania, visceral and cutaneous:

A single dose evenly distributed over 1 to 2 hours.

ACTIONS

An antiprotozoal agent. Specifically active against *Pneumocystis jiroveci*. It is thought to interfere with nuclear metabolism and inhibit the synthesis of DNA, RNA, phospholipids, and proteins. Route of metabolism is unknown. Excreted partially in urine. May accumulate in renal failure.

INDICATIONS AND USES

Treatment and prophylaxis of *Pneumocystis jiroveci* pneumonia (PCP).

Unlabeled uses:

Treatment of trypanosomiasis and visceral and cutaneous leishmaniasis. Aerosol used prophylactically to prevent PCP in high-risk patients.

CONTRAINDICATIONS

None if the diagnosis of *Pneumocystis jiroveci* pneumonia is confirmed.

PRECAUTIONS

Specific use only; establish correct diagnosis. ■ Sulfamethoxazole/trimethoprim is the drug of choice for treatment of *Pneumocystis* pneumonia. Pentamidine causes numerous and serious side effects and is indicated only if the patient does not respond to or tolerate SMZ-TMP. ■ Use extreme caution in patients with hypertension, hypotension, hypoglycemia, hyperglycemia, hypocalcemia, leukopenia, thrombocytopenia, anemia, hepatic or renal dysfunction, ventricular tachycardia, pancreatitis, and Stevens-Johnson syndrome.

Monitor:

Before, during, and after therapy obtain a BUN and SCr (daily), CBC, platelet count, alkaline phosphatase, bilirubin, AST, ALT, serum calcium, and ECG. ■ Has caused fatalities resulting from severe hypotension, hypoglycemia, and cardiac arrhythmias even with the administration of the first dose. Keep patient supine, observe continuously for any sign of adverse reaction, and monitor BP continuously during infusion and afterward until stable. ■ Emergency equipment for resuscitation must be immediately available. ■ Monitor blood glucose levels daily during therapy and several times after therapy is complete. Pancreatic necrosis and very high plasma insulin levels have occurred. May also cause hyperglycemia and diabetes mellitus.

Patient Education:

May cause severe hypotension; remain lying down until BP is stable. ■ Report any unusual bleeding or bruising.

Maternal/Child:

Category C: use only when clearly needed during pregnancy and breast-feeding. Hazards to fetus or infant are unknown. ■ Discontinue breast-feeding.

DRUG/LAB INTERACTIONS

Nephrotoxic effects may be additive with concomitant use with **other nephrotoxic drugs** (e.g., aminoglycosides, amphotericin B, cisplatin, foscarnet, vancomycin). Monitoring of renal function, dose reductions, and/or dose interval adjustments may be required.

SIDE EFFECTS

Occur in over 50% of patients and may be life threatening. Some occur after course of treatment is completed. Acute renal failure, anemia, anorexia, bad taste in mouth, cardiac arrhythmias including ventricular tachycardia, confusion, dizziness, elevated SCr and liver function tests, fever, hallucinations, hyperglycemia, hyperkalemia, hypocalcemia, hypoglycemia, hypotension, leukopenia, nausea, neuralgia, phlebitis, rash, thrombocytopenia.

ANTIDOTE

Discontinue drug for any life-threatening side effects. Notify physician of all side effects. Symptomatic treatment indicated. Resuscitate as necessary.

PENTETATE CALCIUM TRISODIUM INJECTION ■ PENTETATE ZINC TRISODIUM INJECTION BBW

(**PEN**-teh-tayt **KAL**-see-um try-**SO**-dee-um in-**JEK**-shun ■ **PEN**-teh-tayt **ZINK** try-**SO**-dee-um in-**JEK**-shun)
Ca-DTPA ■ Zn-DTPA
Antidote
pH 7.3 to 8.3 ■ pH 6.5 to 7.5

USUAL DOSE

Pretreatment:

Preliminary lab tests desired; see Monitor. See Maternal/Child.

Do not administer more than one dose of either agent in a 24-hour period.

Chelation therapy with either pentetate calcium trisodium (Ca-DTPA) or pentetate zinc trisodium (Zn-DTPA) is most effective when administered within the first 24 hours after internal contamination; however, it should be started as soon as possible after suspected or known internal contamination, even if more than 24 hours have passed. ***Initiation of therapy with a single dose of pentetate calcium trisodium (Ca-DTPA) is preferred because it is more effective than pentetate zinc trisodium (Zn-DTPA) in the first 24 hours.*** Only a single dose of Ca-DTPA is recommended. Use Zn-DTPA if additional chelation therapy is indicated. ***If Ca-DTPA is not available, initiate therapy with pentetate zinc trisodium (Zn-DTPA).***

Adults and pediatric patients 12 years of age or older:

Initial dose: 1 Gm IV (dose is the same for either agent).

After the initial dose, ***maintenance treatment is recommended with pentetate zinc trisodium (Zn-DTPA).*** If Zn-DTPA is not available, therapy may be continued with Ca-DTPA. Ca-DTPA has more toxicity (e.g., depletion of more trace metals, higher rate of mortality, the presence of kidney and liver vacuolization [air or fluid in the tissues], and small bowel hemorrhagic lesions), and concomitant mineral supplements containing zinc are required. Zn-DTPA results in minimal depletion of manganese and magnesium.

Maintenance dose:

1 Gm IV daily (dose is the same for either agent; however, Zn-DTPA is preferred). If Ca-DTPA is used for maintenance doses, transfer to Zn-DTPA as soon as it is available. Zn-DTPA may be administered for days, months, or years depending on the extent of internal contamination and individual response to therapy.

PEDIATRIC DOSE

Pediatric patients under 12 years of age:

Initial dose:

14 mg/kg IV (dose is the same for either agent). Do not exceed 1 Gm. See all comments under Usual Dose.

Maintenance dose:

14 mg/kg IV daily. See all comments under Usual Dose.

DOSE ADJUSTMENTS

No dose adjustment is required in patients with impaired renal function; however, renal impairment may reduce the rate at which the chelators remove radiocontaminants from the body. Hemodialysis may be used to increase the rate of elimination in heavily contaminated patients with renal impairment. The use of high flux dialysis is recommended. The dialysis fluid requires handling with radiation precautions.

DILUTION

Both agents:

IV:

A single dose may be given undiluted as an IV injection or diluted in 100 to 250 mL of D5W, NS, or LR and given as an infusion. To open the ampule, face the point upward and break off the neck with a downward movement.

Nebulized inhalation:

Dilute in a 1:1 ratio with SWFI or NS (equal amounts of drug and diluent).

Filters:

Manufacturer states product may be filtered.

Storage:

Store between 15° to 30° C (59° to 86° F).

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Both agents:

IV injection:

A single dose evenly distributed over 3 to 4 minutes.

IV infusion:

A single dose properly diluted and infused over 30 minutes.

ACTIONS

Both agents:

Hyperosmolar solutions. Form stable chelates with radioactive contaminants (metal ions) found in the circulation, interstitial fluid, and tissues by exchanging calcium or zinc for a metal of greater binding capacity. Most effective with plutonium, americium, or curium. Chelating capacity is greatest immediately and up to approximately 24 hours after internal contamination, when the radiocontaminant is still circulating and readily available for chelation. The ability to chelate decreases with time as the radioactive contaminants incorporate into tissues and become sequestered in the liver and bone. Rapidly distributed throughout the extracellular fluid space. Significant amounts do not penetrate into erythrocytes or other cells. Accumulation in specific organs has not been observed. Metabolism is minimal. Cleared by glomerular filtration. Activity in plasma was not detectable 24 hours after injection. Excreted in urine.

Pentetate calcium trisodium (Ca-DTPA):

More effective than pentetate zinc trisodium (Zn-DTPA) in the first 24 hours. After 24 hours, both drugs are equally effective, but Ca-DTPA is not recommended for continued use.

INDICATIONS AND USES

Treatment of individuals with known or suspected internal contamination with radiocontaminants (e.g., plutonium, americium, or curium) to increase the rates of elimination. ■ If Ca-DTPA is not available, initiate therapy with Zn-DTPA. ■ May also be inhaled as treatment for inhalation contamination; it is absorbed, and inhalation results in comparable elimination of the radiocontaminants.

CONTRAINDICATIONS

None known when used for primary indication.

PRECAUTIONS

Both agents:

For IV use, safety of IM injection not established. ■ Begin chelation treatment as soon as possible after known or suspected internal contamination with radiocontaminants. The ability of both agents to chelate decreases with time as the radioactive contaminants incorporate into tissues. ■ Radioactive iodine is not bound by DTPA. ■ Not expected to be effective for uranium and neptunium because less stable chelates are formed, which results in the deposition of these elements in tissues (including the bone). ■ Studies in patients with impaired renal or hepatic function have not been conducted. Impaired renal function is expected to increase the half-life of Ca-DTPA and Zn-DTPA and to decrease the rate of elimination of the radiocontaminants; see Dose Adjustments. ■ Nebulized chelation therapy may exacerbate asthma; use caution. ■ Contamination with multiple or unknown radiocontaminants may require additional therapies (e.g., Prussian blue, potassium iodide). ■ Manufacturer requests collection of patient treatment data; see prescribing information.

Pentetate calcium trisodium (Ca-DTPA):

Ca-DTPA is associated with depletion of trace metals such as zinc. Loss of zinc, manganese, and magnesium from the small intestine, skeleton, pancreas, and testes is significant; see Monitor. The rate and amount of endogenous metal depletion has been shown to increase with split daily dosing, increased doses, and/or duration of treatment. Depletion of these endogenous metals can interfere with necessary mitotic cellular processes and has resulted in transient inhibition of a metalloenzyme-D-aminolevulinic acid dehydrase (ALAD) in the blood and suppressed hematopoiesis (formation of blood cells). Concomitant supplements containing zinc are required. ■ Use with caution in patients with severe hemochromatosis (a disorder of iron metabolism); deaths have been reported with the use of Ca-DTPA for more than 1 day. ■ Monitor for S/S of asthma exacerbation when administered by the inhalation route.

Pentetate zinc trisodium (Zn-DTPA):

Results in minimal depletion of manganese and magnesium.

Monitor:

Both agents:

If possible, obtain baseline CBC with differential, BUN, serum chemistries and electrolytes, urinalysis, and blood and urine radioassays before initiating treatment. ■ Monitor serum zinc levels, serum creatinine, BUN, electrolytes, urinalysis, and blood cell counts during Ca-DTPA or Zn-DTPA therapy. Give mineral or vitamin plus mineral supplements that contain zinc as appropriate. ■ Measure the radioactivity in blood, urine, and fecal samples weekly to monitor the radioactive contaminant elimination rate. ■ When possible, establish an elimination curve. A quantitative baseline estimate of total internalized transuranium elements and measures of elimination of radioactivity should be obtained by appropriate whole-body counting, bioassay (e.g., biodosimetry), or fecal/urine sample. ■ Care should be taken to minimize radiation exposure to patients and to medical personnel from patients' contaminated excrement (e.g., blood, sputum, urine); this is consistent with institutional good radiation safety practices and patient management procedures. Contact the radiation safety officer. ■ Encourage fluid intake and frequent voiding. Promotes dilution of the radiocontaminant in urine and minimizes radiation exposure to the bladder. ■ Document adverse reactions. ■ See Precautions, Maternal/Child, and Drug/Lab Interactions.

Pentetate calcium trisodium (Ca-DTPA):

If more than one dose of Ca-DTPA is used, monitor lab tests more frequently (with specific attention to serum zinc), and initiate vitamin or mineral supplements containing zinc when appropriate.

Pentetate zinc trisodium (Zn-DTPA):

Based on lab tests, initiate mineral or vitamin plus mineral supplements as appropriate.

Patient Education:

Both agents:

The following steps are required to minimize contamination of others by the radiocontaminants. Use a toilet instead of a urinal and flush several times after each voiding, because treatment increases excretion of radioactivity in the urine. Completely clean up spilled urine or feces, and wash hands thoroughly. Wash clothes that come in contact with blood or urine separately. Drink plenty of fluids; fluid intake is important to aid in flushing radiocontaminants from the system. Void frequently to limit the time that radiocontaminants remain in the bladder. Carefully dispose of expectorant from coughing; do not swallow expectorant. ■ Parents and caregivers need to take extra precautions in handling the urine, feces, and expectorants of pediatric patients to avoid additional exposure to the caregiver or child.

Maternal/Child:

Both agents:

Discontinue breast-feeding whether or not chelation therapy is received. Radiocontaminants are secreted in breast milk. Take precautions when disposing of breast milk. ■ Safety and effectiveness of the nebulized route of administration in pediatric patients has not been established.

Pentetate calcium trisodium (Ca-DTPA):

Category C: use during pregnancy only if potential benefit justifies the potential risk to the fetus. Teratogenicity in humans cannot be ruled out. Birth defects in animals increased with dose, and incidences were higher in early and mid gestation. ■ Treatment of pregnant women with pentetate zinc trisodium (if available) is preferred, except in cases of high internal radioactive contamination. The risk of immediate and delayed radiation-induced toxicity to both the mother and the fetus should be considered in comparison to the risk of pentetate calcium trisodium because it is more effective than pentetate zinc trisodium in the first 24 hours after internal contamination. The use of a single dose of Ca-DTPA with vitamin or mineral supplements containing zinc may be considered as the initial treatment.

Pentetate zinc trisodium (Zn-DTPA):

Category B: treatment of pregnant women should begin and continue with Zn-DTPA. Use only if clearly needed; however, animal studies revealed no evidence of impaired fertility or harm to the fetus.

Elderly:

Specific information not available.

DRUG/LAB INTERACTIONS

Specific drug interactions have not been studied. ■ Contamination with **multiple or unknown radiocontaminants** may require the use of additional therapies (e.g., Prussian blue, potassium iodide).

SIDE EFFECTS

Pentetate calcium trisodium (Ca-DTPA):

Allergic reactions, chest pain, dermatitis, diarrhea, headache, injection site reactions, light-headedness, metallic taste, and nausea have occurred. Prolonged treatment may result in depletion of manganese, magnesium, zinc and, possibly, metalloproteinases. Cough and/or wheezing occurred with nebulized Ca-DTPA.

Pentetate zinc trisodium (Zn-DTPA):

Headache, light-headedness, and pelvic pain have been reported. Exacerbation of asthma may occur with nebulized chelation therapy. Allergic reactions may occur.

ANTIDOTE

Keep physician informed of side effects; symptomatic treatment is indicated. Treat a hypersensitivity reaction as indicated (oxygen, antihistamines [e.g., diphenhydramine], epinephrine, and corticosteroids [e.g., methylprednisolone (Solu-Medrol)]). Maintain a patent airway. Resuscitate as necessary.

PENTOBARBITAL SODIUM

(**PEN**-toh-**bar**-bih-tal **SO**-dee-um)
Nembutal Sodium
Barbiturate
Sedative-hypnotic
Anticonvulsant
pH 9 to 10.5

USUAL DOSE

Pretreatment:

See Maternal/Child.

Pentobarbital:

100 mg initially. Wait 1 full minute between each dose to determine drug effect. Additional doses in increments of 25 to 50 mg may be given as indicated. Maximum dosage ranges from 200 to 500 mg.

Barbiturate coma:

Loading dose:

3 to 10 mg/kg over 30 minutes to 3 hours.

Maintenance dose:

1.5 to 2 mg/kg every 1 to 2 hours or an infusion of 0.5 to 3 mg/kg/hr. Adjust to maintain pentobarbital blood level between 110 and 177 mm/L (25 to 40 mg/dL) or ICP below 25 Torr.

PEDIATRIC DOSE

See Maternal/Child.

1 to 3 mg/kg slowly until asleep. Maximum dose 100 mg/24 hr.

Barbiturate coma:

See Usual Dose. An alternate source suggests ***Loading dose:*** 10 to 15 mg/kg over 1 to 2 hours. ***Maintenance dose:*** Begin with 1 mg/kg/hr; increase to 2 to 3 mg/kg/hr to maintain EEG burst suppression.

DOSE ADJUSTMENTS

Reduce dose in impaired renal or hepatic function; usually required in the debilitated or elderly. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted or, preferably, may be further diluted in SWFI, NS, or Ringer’s injection. Any desired amount of diluent may be used. 9 mL of diluent with 1 mL of pentobarbital (50 mg) equals 5 mg/mL. Use only absolutely clear solutions.

COMPATIBILITY

Manufacturer states, “Should not be admixed with any other medication or solution.” May precipitate in acidic solutions.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

50 mg or fraction thereof over 1 minute. Titrate slowly to desired effect. Rapid injection rate may cause symptoms of overdose (e.g., serious respiratory depression).

Barbiturate coma:

See specific dose recommendations.

ACTIONS

A sedative, hypnotic barbiturate of short duration with anticonvulsant effects. Pentobarbital is a CNS depressant. Onset of action is prompt by the IV route and lasts about 3 to 4 hours. Will effectively depress the motor cortex if adequate doses are administered. Pain perception is unimpaired. Reportedly reduces cerebral blood flow and thus reduces cerebral edema and intracranial pressure. Detoxified in the liver and excreted fairly quickly in the urine in changed form. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Preanesthetic sedation. ■ Dental and minor surgical sedation. ■ Control of convulsions caused by disease/drug poisoning. ■ Short-term hypnotic. ■ Sedation in psychotic states.

Unlabeled uses:

High doses have been used to induce coma in the management of cerebral ischemia and increased intracranial pressure. Has been most effective in patients under 35 years of age or in closed head injuries.

CONTRAINDICATIONS

Acute or chronic pain, delivery (when maximum drug effect would be at the time of delivery), history of porphyria, known hypersensitivity to barbiturates, severely impaired liver function especially with any signs of hepatic coma, severe respiratory disease or respiratory depression.

PRECAUTIONS

IV route usually reserved for critical situations. ■ Use caution in status asthmaticus, shock, severe renal or liver disease, depressive states after convulsions, shock, and in the elderly. ■ Use caution in acute or chronic pain. ■ Status epilepticus can occur from too-rapid withdrawal. ■ May be habit forming. Use caution in the presence of fever, diabetes, hyperthyroidism, or severe anemia; may increase side effects. ■ Benzodiazepines are generally preferred for sedation.

Monitor:

Record BP, pulse, and respirations every 3 to 5 minutes. Keep patient under constant observation. ■ Maintain a patent airway. ■ Treat the cause of a convulsion. ■ Highly alkaline; determine absolute patency of vein; use of large veins preferred to prevent thrombosis. Avoid extravasation. Intra-arterial injection will cause gangrene. ■ Monitor phenytoin and barbiturate levels when both drugs are used concurrently. ■ Monitor hematopoietic, renal, and hepatic systems in extended therapy. ■ See Drug/Lab Interactions.

Patient Education:

Avoid alcohol and other CNS depressants (e.g., antihistamines, diazepam). ■ May be habit forming. ■ May require alternate birth control.

Maternal/Child:

Category D: avoid pregnancy; will cause birth defects. ■ May cause drowsiness in the nursing infant. ■ See Contraindications. ■ May cause paradoxical excitement in pediatric patients.

Elderly:

Often have increased sensitivity to barbiturates; may cause marked excitement, depression, confusion, and increased risk of barbiturate-induced hypothermia. ■ See Dose Adjustments and Precautions. ■ Consider age-related hepatic or renal impairment and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

Use extreme caution if any **other CNS depressants** have been given, such as alcohol, narcotic analgesics, anesthetics, antidepressants, antihistamines, hypnotics, MAO inhibitors, phenothiazines, sedatives, aminoglycoside antibiotics, or tranquilizers; potentiation with respiratory depression may occur. ■ Inhibits effectiveness of **propranolol, corticosteroids, doxycycline, oral anticoagulants, oral contraceptives, quinidine, and theophylline.** Capable of innumerable interactions with many drugs. ■ May increase orthostatic hypotension with **furosemide**. ■ Monitor **phenytoin** and barbiturate levels when both drugs are used concurrently. ■ May inhibit **vitamin D** metabolism with extended use.

SIDE EFFECTS

Average dose:

Depression, dermatitis, facial edema, fever, hypotension, neonatal apnea, pain at or below injection site, respiratory depression (hypoventilation), thrombocytopenic purpura.

Overdose:

Apnea, coma, cough reflex depression, flat EEG (reversible unless hypoxic damage has occurred), hypotension, laryngospasm, lowered body temperature, pulmonary edema, renal shutdown, respiratory depression, sluggish or absent reflexes.

ANTIDOTE

Discontinue drug immediately for pain at or below injection site. Notify the physician of any side effects. Symptomatic and supportive treatment is most important in overdose. Maintain an adequate airway with artificial ventilation if indicated. Keep the patient warm. IV volume expanders and IV fluids will help maintain adequate circulation. Diuretics or hemodialysis will promote the elimination of the drug. Vasopressors will maintain BP.

PENTOSTATIN BBW

(**PEN**-toh-**stah**-tin)
2-Deoxycoformycin, Nipent
Antineoplastic (antibiotic)
pH 7 to 8.5

USUAL DOSE

Pretreatment:

Baseline studies and prehydration are required before administration; see Monitor.

Pentostatin:

4 mg/M² every other week. Do not exceed recommended dose; see Precautions. If there is no major toxicity and improvement is continuous, treat until a complete response is achieved, then administer two additional doses. Do not treat beyond 12 months.

DOSE ADJUSTMENTS

Reduced dose and benefit-versus-risk assessment may be required with impaired renal function (CrCl below 60 mL/min); insufficient data available. Two patients with impaired renal function (CrCl 50 to 60 mL/min) achieved complete response without unusual adverse events when treated with 2 mg/M². ■ Withhold dose if SCr elevated; obtain CrCl. ■ Withhold dose if the absolute neutrophil count falls from a baseline of greater than 500 cells/mm³ before therapy to less than 200 cells/mm³ during treatment. Resume treatment when count returns to predose levels.

DILUTION

Specific techniques required; see Precautions. Diluent (5 mL SWFI) provided; dissolve completely; will yield 2 mg/mL. May be given by IV injection or further diluted in 25 to 50 mL NS or D5W; 25 mL yields 0.33 mg/mL, 50 mL yields 0.18 mg/mL. Treat spills or waste with a 5% sodium hypochlorite solution before disposal.

Storage:

Refrigerate before initial reconstitution. Store at room temperature and use within 8 hours after initial reconstitution or dilution for infusion.

COMPATIBILITY

Does not interact with PVC infusion containers or administration sets at concentrations specified for dilution.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Follow each dose with an additional 500 mL of prehydration infusion fluids.

IV injection:

A single dose over 1 minute.

Infusion:

A single dose over 20 to 30 minutes.

ACTIONS

Mechanism of action is not known, but it is cytotoxic as a result of its potent inhibition of the enzyme adenosine deaminase (ADA). Blocks DNA and RNA synthesis and causes DNA damage. Average terminal half-life of 6 hours is extended to 18 hours in patients with impaired renal function (CrCl less than 50 mL/min). Inhibits ADA for up to 1 week; actual response may not occur for months. Primarily excreted in urine.

INDICATIONS AND USES

Single-agent treatment of both untreated patients and alpha-interferon–refractory hairy cell leukemia (HCL) patients with active disease as defined by clinically significant anemia, neutropenia, thrombocytopenia, or disease-related symptoms.

Unlabeled uses:

Treatment of chronic lymphocytic leukemia, prolymphocytic leukemia, non-Hodgkin lymphoma, cutaneous T-cell lymphoma, and peripheral T-cell lymphomas.

CONTRAINDICATIONS

Hypersensitivity to pentostatin; see Drug/Lab Interactions.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Assess drug profile before administration. ■ Severe renal, liver, pulmonary, and CNS toxicities have occurred at higher doses; do not exceed recommended dose. ■ Usually administered by or under the supervision of a physician specialist. ■ Myelosuppression, especially neutropenia, is most severe during the first few courses of treatment. ■ Must consider risk/benefit in patients with some bone marrow suppression, the possibility of chickenpox or herpes zoster, a history of gout or urate renal stones, renal function impairment, or previous cytotoxic drug or radiation therapy. Use extreme caution. ■ After 6 months of treatment, assess for response; if partial or complete response is not evident, discontinue treatment. If partial response is evident, re-evaluate as indicated but do not treat beyond 12 months.

Monitor:

Monitor CBC (including differential and platelet count) and SCr before each dose and as indicated. Blood chemistries, including serum uric acid, and a CrCl assay are required before and during treatment. ■ Prehydration with 500 to 1,000 mL D5/½NS or an equivalent is required. An additional 500 mL is required postadministration. ■ Treatment of patients with infection may exacerbate symptoms and cause death. Control infection before treatment is initiated. Withhold treatment if an active infection occurs; resume when infection is controlled. ■ Prophylactic antiemetics recommended (e.g., prochlorperazine [Compazine], ondansetron [Zofran]); continue for 48 to 72 hours. ■ Observe closely for severe rashes, nervous system toxicity, and myelosuppression (especially after initial cycles); pentostatin may have to be withheld or discontinued. ■ For severe neutropenia beyond the initial cycles, evaluate for disease status, including a bone marrow examination. ■ Assess response to treatment with periodic monitoring of peripheral blood for hairy cells. Bone marrow aspirates and biopsies may be required at 2- to 3-month intervals. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Consider birth control options; effective birth control recommended. ■ Report rashes, symptoms of infection, or bruising and bleeding immediately. ■ SeeAppendix D, p. 1311.

Maternal/Child:

Category D: avoid pregnancy; can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients under 18 years of age not established.

Elderly:

Consider decreased renal function.

DRUG/LAB INTERACTIONS

Assess drug profile before administration. ■ Do not use with **fludarabine**; may increase risk of fatal pulmonary toxicity. ■ Combination therapy with **carmustine**, **etoposide**, **and high-dose cyclophosphamide** as part of the ablative regimen for bone marrow transplant has caused acute pulmonary edema and hypotension. Deaths have occurred. ■ Pentostatin enhances the effects of **vidarabine**. Combined use of these agents may result in an increase in adverse reactions associated with each drug. The therapeutic benefit of this drug combination has not been established. ■ May cause skin rash with **allopurinol.** ■ Elevates **liver function tests;** usually reversible. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Uric acid levels may increase; increased dose of **gout agents** (e.g., colchicine, probenecid, sulfinpyrazone) may be indicated. ■ Leukopenia and thrombocytopenia increased by **agents causing blood dyscrasias** (e.g., anticonvulsants [phenytoin], penicillins, phenothiazines, and many others).

SIDE EFFECTS

Anemia, anorexia, chills, cough, diarrhea, fatigue, fever, GU disorders, headache, hepatic disorders/elevated liver function tests, hypersensitivity reactions, infection, leukopenia, lung disorders, myalgia, nausea, neurologic disorders/CNS, pain, rashes, skin disorders, thrombocytopenia, upper respiratory infections, and vomiting occur in 10% of patients and may require discontinuation of treatment. Abdominal pain; abnormal ECG; abnormal thinking; abnormal vision; anxiety; arthralgia; asthenia; back pain; bronchitis; cardiac arrhythmias; chest pain; confusion; conjunctivitis; constipation; depression; dizziness; dry skin; dyspnea; dysuria; ear pain; ecchymosis; eczema; elevated BUN, creatinine, and LDH; epistaxis; eye pain; flatulence; flu syndrome; hematuria; hemorrhage; herpes simplex; herpes zoster; insomnia; lung edema; lymphadenopathy; maculopapular rash; malaise; neoplasm; nervousness; paresthesia; peripheral edema; petechiae; pharyngitis; pneumonia; pruritus; rhinitis; seborrhea; sinusitis; skin discoloration; somnolence; stomatitis; sweating; thrombophlebitis; vesiculobullous rash; weight loss; and death have occurred in 3% to 10% or more of patients.

ANTIDOTE

Keep physician informed of all side effects; most will be treated symptomatically if indicated. Withhold dose and notify physician for elevated SCr, absolute neutrophil count below 200 cells/mm^3, myelosuppression, infection, CNS toxicity, or severe rash. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Overdose may cause death due to severe renal, hepatic, pulmonary, or CNS toxicity. There is no specific antidote. Supportive therapy as indicated will help sustain the patient.

PERAMIVIR

(per-**AM**-i-vir)
Rapivab
Antiviral
(Influenza virus neuraminidase inhibitor)
pH 5.5 to 8.5

USUAL DOSE

Administer peramivir within 2 days of onset of symptoms of influenza.

Adults and adolescents (13 years of age and older):

A single dose of 600 mg administered as an IV infusion over 15 to 30 minutes.

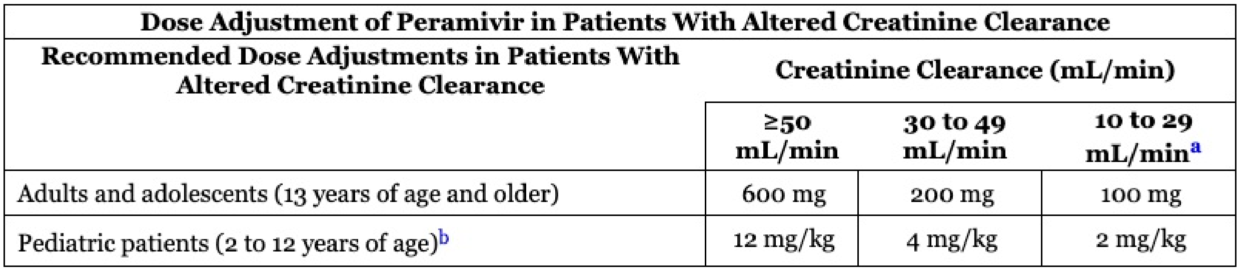
PEDIATRIC DOSE

Pediatric patients (2 to 12 years of age):

A single 12 mg/kg dose (up to a maximum of 600 mg) administered as an IV infusion over 15 to 30 minutes.

DOSE ADJUSTMENTS

No dose adjustment is required in patients with a creatinine clearance of 50 mL/min or higher. ■ Reduce dose in patients with a baseline creatinine clearance below 50 mL/min using the recommendations in the following chart.



Dose Adjustment of Peramivir in Patients With Altered Creatinine Clearance

Recommended Dose Adjustments in Patients With Altered Creatinine Clearance	**Creatinine Clearance (mL/min)**		
	≥50 mL/min	**30 to 49 mL/min**	**10 to 29 mL/min[a]**
Adults and adolescents (13 years of age and older)	600 mg	200 mg	100 mg
Pediatric patients (2 to 12 years of age)[b]	12 mg/kg	4 mg/kg	2 mg/kg

[a] In patients with chronic renal impairment maintained on hemodialysis, administer after dialysis at a dose adjusted based on renal function.

[b] Up to a maximum of 600 mg.

■ No dose adjustment is required based on gender, impaired hepatic function, weight, or race (was evaluated primarily in Asians and Whites).

DILUTION

Available in single-use vials containing 200 mg/20 mL (10 mg/mL) as a clear, colorless solution. Contains no preservatives. Do not use if seal over bottle opening is broken or missing. Calculate the number of vial(s) required for the recommended dose. Withdraw the required volume of peramivir and dilute with NS, ½NS, D5W, or LR to a maximum volume of 100 mL.

Filters:

No data available from manufacturer.

Storage:

Before use, store in original cartons at CRT. Administer fully diluted solutions immediately or refrigerate at 2° to 8° C (36° to 46° F) for up to 24 hours. If refrigerated, allow the diluted solution to reach room temperature, then administer immediately. Discard any unused diluted solution of peramivir after 24 hours.

COMPATIBILITY

Compatible with NS, ½NS, D5W, or LR. Also **compatible** with materials commonly used for administration such as polyvinylchloride (PVC) bags and PVC-free bags, polypropylene syringes, and polyethylene tubing. Manufacturer states, “Do not mix or co-infuse with other intravenous medications.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 15 to 30 minutes.

ACTIONS

Peramivir is an antiviral drug with activity against the influenza virus. It is an inhibitor of the influenza virus neuraminidase, an enzyme that releases viral particles from the plasma membrane of infected cells. Maximum serum concentration is reached by the end of the infusion. In vitro binding to human plasma proteins is less than 30%. Not significantly metabolized in humans. Elimination half-life is approximately 20 hours. Primarily excreted as unchanged drug in urine.

INDICATIONS AND USES

Treatment of acute uncomplicated influenza in patients 2 years of age and older who have been symptomatic for no more than 2 days.

Limitations of use:

Efficacy of peramivir is based on clinical trials of naturally occurring influenza in which the predominant influenza infections were influenza A virus; a limited number of subjects infected with influenza B virus were enrolled. ■ Influenza viruses change over time. Emergence of resistance substitutions could decrease drug effectiveness. Other factors (e.g., changes in viral virulence) might also diminish the clinical benefit of antiviral drugs. Prescribers should consider available information on influenza drug susceptibility patterns and treatment effects when deciding whether to use peramivir. ■ The efficacy of peramivir could not be established in patients with serious influenza requiring hospitalization.

CONTRAINDICATIONS

Known serious hypersensitivity or anaphylactic reaction to peramivir or any component of the product.

PRECAUTIONS

Rare cases of serious skin reactions, including erythema multiforme, have been reported. Cases of anaphylaxis and Stevens-Johnson syndrome have been reported in post-marketing surveillance. ■ Influenza can be associated with a variety of neurologic and behavioral symptoms that can include events such as abnormal behavior, delirium, and hallucinations, which in some cases result in fatal outcomes. These events may occur in the setting of encephalitis or encephalopathy but also can occur in uncomplicated influenza. Neuropsychiatric events (e.g., delirium and abnormal behavior) have been reported in patients (primarily pediatric patients) with influenza who are receiving neuraminidase inhibitors, including peramivir. The contribution of peramivir to these events has not been established. ■ There is no evidence for the efficacy of peramivir in any illness caused by agents other than influenza viruses. Serious bacterial infections may begin with influenza-like symptoms or may coexist with or occur as complications during the course of influenza. Peramivir has not been shown to prevent such complications. ■ Circulating seasonal influenza strains expressing neuraminidase resistance–associated substitutions have been observed in individuals who have not received peramivir. Prescribers should consider available information from the CDC on influenza virus drug susceptibility patterns and treatment effects when deciding whether to use peramivir. ■ Cross-resistance between peramivir, oseltamivir, and zanamivir was observed in neuraminidase biochemical assays and cell culture assays. The clinical impact of this reduced susceptibility is unknown. ■ Has not been studied in patients with impaired hepatic function; however, because peramivir is cleared in urine by glomerular filtration, no clinically relevant problems are expected.

Monitor:

Monitor for serious skin reactions. Appropriate treatment should be instituted if a serious skin reaction occurs or is suspected. ■ Monitor for potential secondary bacterial infections and treat with antibiotics as appropriate. ■ Monitor for S/S of a hypersensitivity reaction (e.g., anaphylaxis, hypotension, rash, tightness of the chest, urticaria, wheezing). ■ Patients with influenza should be closely monitored for signs of abnormal behavior.

Patient Education:

There is a risk of serious skin reactions. Seek immediate medical attention if a skin reaction occurs. ■ There is a risk of neuropsychiatric events in patients with influenza. Patients should contact their physician if they experience signs of abnormal behavior after receiving peramivir. ■ Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath, wheezing).

Maternal/Child:

Use during pregnancy only if clearly needed. Pregnant women are at higher risk for severe complications from influenza, which may lead to adverse pregnancy and/or fetal outcomes. ■ There are no data on the presence of peramivir in human milk, the effects on the breast-fed infant, or the effects on milk production. Consider risk versus benefit. ■ Safety and effectiveness in pediatric patients 2 to 17 years of age have been established. ■ Safety and effectiveness in pediatric patients under 2 years of age have not been established.

Elderly:

Numbers in clinical studies were insufficient to determine if elderly patients respond differently than do younger subjects.

DRUG/LAB INTERACTIONS

The concurrent use of peramivir with **live attenuated influenza vaccine** (LAIV) intranasal has not been evaluated. Because of the potential for interference between these two products, avoid the use of LAIV within 2 weeks before or 48 hours after administration of peramivir unless medically indicated. For LAIV, antiviral drugs may inhibit viral replication and may reduce vaccine efficacy. ■ Inactivated influenza vaccine can be administered at any time.

SIDE EFFECTS

Adult and pediatric patients:

The most common adverse reaction is diarrhea. Serious skin and hypersensitivity reactions (including anaphylaxis) and neuropsychiatric events have occurred. Constipation; decreased neutrophils; hypertension; increased ALT, AST, creatine phosphokinase, and serum glucose; and insomnia were also reported.

Pediatric patients:

Fever, proteinuria, tympanic membrane erythema, and vomiting.

Post-Marketing:

Abnormal behavior, anaphylaxis/anaphylactoid reactions, exfoliative dermatitis, hallucination, rash, and Stevens-Johnson syndrome.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat overdose with general supportive measures, including monitoring of vital signs and observation of the clinical status of the patient. There is no specific antidote. Treat hypersensitivity reactions as indicated (e.g., diphenhydramine, epinephrine, albuterol) and resuscitate as necessary. Removed by hemodialysis.

PERTUZUMAB BBW

(per-**TOOZ**-ue-mab)
Perjeta
Recombinant monoclonal antibody
Antineoplastic
pH 6

USUAL DOSE

Pretreatment:

Verify pregnancy status. Preassessment is required; see Monitor and Precautions.

Pertuzumab is given in combination with trastuzumab (Herceptin) or trastuzumab hyaluronidase-oysk (Herceptin Hylecta) and docetaxel (Taxotere) or anthracycline-based chemotherapy regimens. See monographs of any concomitantly administered medications; preassessment and premedication indicated. Pertuzumab, the trastuzumab product, and docetaxel should be administered sequentially. Pertuzumab and the trastuzumab product can be given in any order. Docetaxel should be administered after pertuzumab and the trastuzumab product administrations are complete. An observation period of 30 to 60 minutes is recommended after each pertuzumab infusion and before beginning any subsequent administration of the trastuzumab product or docetaxel. In patients receiving anthracycline-based regimen, pertuzumab and the trastuzumab product should be administered after completion of the anthracycline.

Metastatic Breast Cancer (MBC)

Initial doses:

Pertuzumab:

840 mg as an infusion over 60 minutes.

Trastuzumab:

8 mg/kg as an infusion over 90 minutes. **OR**

Trastuzumab hyaluronidase-oysk:

When pertuzumab is administered with trastuzumab hyaluronidase-oysk instead of trastuzumab (Herceptin), the recommended initial dose of trastuzumab hyaluronidase-oysk is 600 mg/10,000 units (600 units of trastuzumab and 10,000 units hyaluronidase) administered SC over approximately 2 to 5 minutes once every 3 weeks irrespective of the patient’s body weight.

Docetaxel:

75 mg/M² as an infusion over 60 minutes.

Subsequent doses:

Begin 3 weeks after initial doses.

Pertuzumab:

420 mg administered as an infusion over 30 to 60 minutes and repeated every 3 weeks.

Trastuzumab:

6 mg/kg as an infusion over 30 to 90 minutes and repeated every 3 weeks.

Docetaxel:

If the initial dose is well tolerated, the dose may be escalated to 100 mg/M² and repeated every 3 weeks.

Neoadjuvant Treatment of Breast Cancer

Administer pertuzumab every 3 weeks for 3 to 6 cycles as part of one of the following treatment regimens for early breast cancer. ***Actual initial and subsequent doses of pertuzumab, the trastuzumab product, and docetaxel are the same as above in MBC.*** Note all comments under Usual Dose.

- Four preoperative cycles of pertuzumab in combination with trastuzumab or trastuzumab hyaluronidase-oysk and docetaxel followed by 3 postoperative cycles of fluorouracil, epirubicin, and cyclophosphamide (FEC).
- Three or four preoperative cycles of FEC alone followed by 3 or 4 preoperative cycles of pertuzumab in combination with docetaxel and trastuzumab or trastuzumab hyaluronidase-oysk.
- Six preoperative cycles of pertuzumab in combination with docetaxel,

carboplatin, and trastuzumab (TCH) or trastuzumab hyaluronidase-oysk (escalation of docetaxel above 75 mg/M^2 is not recommended).

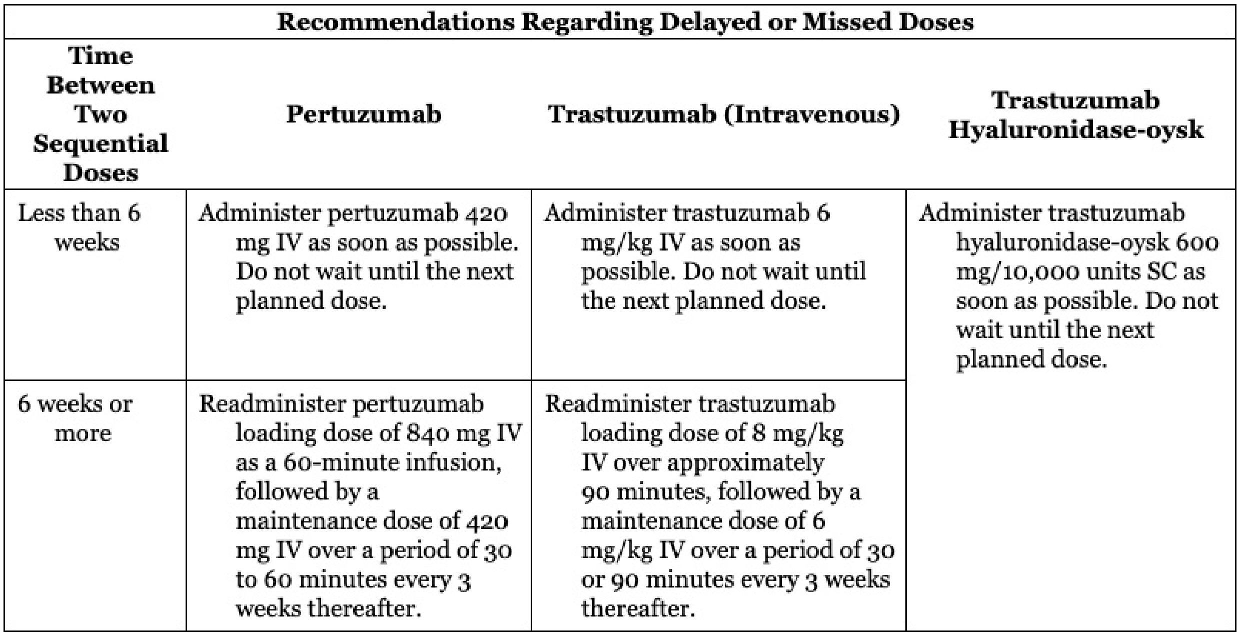
- Four preoperative cycles of dose-dense doxorubicin and cyclophosphamide (ddAC) alone followed by 4 preoperative cycles of pertuzumab in combination with paclitaxel and trastuzumab or trastuzumab hyaluronidase-oysk.

Following surgery, patients should continue to receive pertuzumab and the trastuzumab product to complete 1 year of treatment (up to 18 cycles).

Adjuvant Treatment of Breast Cancer

Pertuzumab should be administered in combination with trastuzumab or trastuzumab hyaluronidase-oysk every 3 weeks for a total of 1 year (up to 18 cycles) or until disease recurrence or unmanageable toxicity, whichever occurs first, as part of a complete regimen for early breast cancer, including standard anthracycline and/or taxane-based chemotherapy. Pertuzumab and the trastuzumab product should start on Day 1 of the first taxane-containing cycle.

DOSE ADJUSTMENTS



Recommendations Regarding Delayed or Missed Doses

Time Between Two Sequential Doses	Pertuzumab	Trastuzumab (Intravenous)	Trastuzumab Hyaluronidase-oysk
Less than 6 weeks	Administer pertuzumab 420 mg IV as soon as possible. Do not wait until the next planned dose.	Administer trastuzumab 6 mg/kg IV as soon as possible. Do not wait until the next planned dose.	Administer trastuzumab hyaluronidase-oysk 600 mg/10,000 units SC as soon as possible. Do not wait until the next planned dose.
6 weeks or more	Readminister pertuzumab loading dose of 840 mg IV as a 60-minute infusion, followed by a maintenance dose of 420 mg IV over a period of 30 to 60 minutes every 3 weeks thereafter.	Readminister trastuzumab loading dose of 8 mg/kg IV over approximately 90 minutes, followed by a maintenance dose of 6 mg/kg IV over a period of 30 or 90 minutes every 3 weeks thereafter.	

■ Dose reductions are not recommended for pertuzumab. ■ Pertuzumab should be discontinued if trastuzumab or trastuzumab hyaluronidase-oysk treatment is discontinued. ■ Discontinue immediately for a serious hypersensitivity reaction. ■ For chemotherapy dose modifications, see relevant prescribing information. ■ The recommendations on dose modifications in the event of LVEF dysfunction are indicated in the following chart.

Dose Modifications for LVEF Ventricular Dysfunction						
	Pretreatment LVEF	**Monitor LVEF:**	**Withhold Pertuzumab and Trastuzumab Product for at Least 3 Weeks for an LVEF Decrease to:**		**Resume Pertuzumab and Trastuzumab Product After 3 Weeks if LVEF Has Recovered to:**	
Metastatic breast cancer	≥50%	Every 12 weeks	Either		Either	
			<40%	40% to 45% with a fall of ≥10% points below pretreatment value	>45%	40% to 45% with a fall of <10% points below pretreatment value
Early breast cancer	≥55%[a]	Every 12 weeks (once during neoadjuvant therapy)	<50% with a fall of ≥10% points below pretreatment value		Either	
				≥50%	<10% points below pretreatment value	

[a] For patients receiving anthracycline-based chemotherapy, a LVEF of ≥50% is required after completion of anthracyclines and before starting pertuzumab and trastuzumab or trastuzumab hyaluronidase-oysk.

■ No dose adjustment is indicated in patients with mild or moderate renal impairment. In patients with severe renal impairment (CrCl less than 30 mL/min), no dose adjustments can be recommended because of the limited pharmacokinetic data available. ■ See Rate of Administration, Precautions, Monitor, and Antidote.

DILUTION

Withdraw the calculated dose of pertuzumab from the vial(s) and inject into a 250-mL PVC or non-PVC polyolefin infusion bag of NS. Invert diluted solution gently to mix. ***Do not shake.*** Dilute only with NS. Do not use D5W. Immediate use is preferred.

Filters:

Not required by manufacturer; additional data not available.

Storage:

Store vials in carton in refrigerator at 2° to 8° C (36° to 46° F). Do not freeze. Do not shake. Protect from light. Immediate use preferred; if the diluted solution is not used immediately, however, it can be refrigerated for 24 hours.

COMPATIBILITY

Manufacturer states, “Do not mix pertuzumab with other drugs” and lists as **incompatible** with D5W.

RATE OF ADMINISTRATION

For IV infusion only; do not administer as an IV push or IV bolus. The rate of infusion may be slowed or interrupted if the patient develops an infusion-associated reaction. Discontinue immediately for a serious hypersensitivity reaction.

Pertuzumab:

Administer the ***initial dose*** over 60 minutes. Administer ***subsequent doses*** over 30 to 60 minutes. An observation period of 30 to 60 minutes is recommended after each pertuzumab infusion and before beginning any subsequent administration of trastuzumab or trastuzumab hyaluronidase-oysk, or docetaxel.

Trastuzumab:

Administer the ***initial dose*** over 90 minutes. Administer ***subsequent doses*** over 30 to 90 minutes. May be administered before or after pertuzumab.

Trastuzumab hyaluronidase-oysk:

See Usual Dose.

Docetaxel:

Each dose equally distributed over 60 minutes. Administer after pertuzumab and trastuzumab product administrations have been completed.

ACTIONS

A recombinant humanized monoclonal antibody. It targets the human epidermal growth factor receptor 2 protein (HER2) and blocks ligand-dependent heterodimerization of HER2 with other HER family members, including EGFR, HER3, and HER4. By inhibiting specific pathways, cell growth arrest and apoptosis can occur. Pertuzumab also mediates antibody-dependent, cell-mediated cytotoxicity. While using pertuzumab alone inhibits the proliferation of human tumor cells, the combination of pertuzumab and the trastuzumab product greatly augments antitumor activity in HER2-overexpressing xenograft models. Steady-state concentration can be reached after the first maintenance dose. Median half-life was 18 days.

INDICATIONS AND USES

Pertuzumab in combination with trastuzumab or trastuzumab hyaluronidase-oysk and docetaxel is indicated for the treatment of patients with HER2-positive metastatic breast cancer who have not received prior anti-HER2 therapy or chemotherapy for metastatic disease. ■ Pertuzumab in combination with trastuzumab or trastuzumab hyaluronidase-oysk and chemotherapy is indicated for the neoadjuvant treatment of patients with HER2-positive, locally advanced, inflammatory, or early-stage breast cancer (either greater than 2 cm in diameter or node positive) as part of a complete treatment regimen for early breast cancer; and the adjuvant treatment of patients with

HER2-positive early breast cancer at high risk of recurrence.

CONTRAINDICATIONS

Known hypersensitivity to pertuzumab or to any of its excipients.

PRECAUTIONS

For IV infusion only; do not administer as an IV push or IV bolus. ■ Assess HER2 status before beginning pertuzumab therapy. Testing should be done by a laboratory with demonstrated proficiency in the testing process using FDA-approved tests. In clinical studies, the only patients who have received benefit from pertuzumab therapy are those with HER2 protein. ■ Can cause fetal harm when administered to pregnant women; see Patient Education and Maternal/Child. ■ Administered by or under the direction of a physician specialist. ■ Adequate laboratory and supportive medical resources must be available. ■ Emergency equipment and drugs for treatment of left ventricular dysfunction and/or hypersensitivity or infusion reactions must be immediately available; see Antidote. ■ Can result in subclinical and clinical cardiac failure. Evaluate left ventricular function in all patients before and during treatment with pertuzumab. Decreases in LVEF with drugs that block HER2 activity, including pertuzumab, have been reported. Patients who have received prior anthracyclines or radiotherapy to the chest wall may be at higher risk for decreased LVEF. ■ Pertuzumab has not been studied in patients with a pretreatment LVEF value of 50% or less, a prior history of CHF, decreases in LVEF to less than 50% during prior trastuzumab therapy, or conditions that could impair left ventricular function such as uncontrolled hypertension, recent MI, serious cardiac arrhythmia requiring treatment, or a cumulative prior anthracycline exposure to greater than 360 mg/M^2 of doxorubicin or its equivalent. ■ Hypersensitivity reactions, including anaphylaxis (and fatal events), and infusion reactions (including fatal events) have occurred. ■ Trastuzumab products and other concomitantly administered antineoplastics also have extensive precautions and monitoring requirements; a review of their monographs is imperative. ■ Effects on patients with severe renal impairment and/or hepatic impairment have not been studied. ■ A protein substance; has the potential for immunogenicity.

Monitor:

Assess LVEF before beginning therapy and at regular intervals during treatment to verify that it remains within expected parameters; see Dose Adjustments. ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, chills, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, urticaria) or infusion reaction (e.g., asthenia, chills, dysgeusia, fatigue, fever, headache, myalgia, vomiting). Observe closely for 60 minutes after the first infusion and for at least 30 minutes after subsequent infusions. ■ Trastuzumab products and other concomitantly administered antineoplastics have additional monitoring requirements.

Patient Education:

Avoid pregnancy; effective contraception required while receiving therapy and for 7 months following the last dose of pertuzumab in combination with trastuzumab products. ■ During infusion, promptly report chills and/or fever and other S/S of an infusion or hypersensitivity reaction (e.g., chest pain, dizziness, feeling faint, flushing, hives, itching, nausea, pruritus, rash, shortness of breath). ■ Promptly report new onset or worsening of shortness of breath, cough, swelling of ankles/legs, swelling of the face, palpitations, weight gain of more than 5 pounds in 24 hours, dizziness, or loss of consciousness. ■ Report a suspected pregnancy immediately. If a pregnancy occurs during therapy, if pertuzumab is administered during a pregnancy, or if pregnancy occurs within 7 months of the last dose of pertuzumab, report pregnancy immediately to the Genentech Adverse Event Line. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy; may cause fetal harm. Exposure can result in embryo-fetal death and birth defects. Studies in animals have resulted in oligohydramnios, delayed renal development, and embryo-fetal deaths. In post-marketing reports for trastuzumab (another HER2 receptor antagonist), use during pregnancy resulted in cases of oligohydramnios and oligohydramnios sequence manifesting as pulmonary hypoplasia, skeletal abnormalities, and neonatal death. Women who receive pertuzumab in combination with trastuzumab products during pregnancy or within 7 months before conception should be monitored for oligohydramnios. If oligohydramnios occurs, perform fetal testing that is appropriate for gestational age and consistent with community standards of care. ■ Consider risk versus benefit with breast-feeding. Consideration should also take into account the elimination half-life of pertuzumab and the trastuzumab wash-out period of 7 months. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety were observed between patients 65 years of age and older and patients under 65 years of age. There are too few patients 75 years of age and older to draw conclusions on the efficacy in this age-group.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been done.

SIDE EFFECTS

Pertuzumab administered in combination with the trastuzumab product and docetaxel:

The most common side effects were alopecia, diarrhea, fatigue, nausea, neutropenia, peripheral neuropathy, and rash. Anemia, thrombocytopenia, and vomiting were reported when carboplatin was added to the regimen. The most common Grade 3 and 4 adverse reactions were anemia, asthenia, diarrhea, fatigue, febrile neutropenia, leukopenia, neutropenia, and peripheral neuropathy.

Pertuzumab in combination with the trastuzumab product and chemotherapy for the adjuvant treatment of breast cancer:

The most common side effects included alopecia, diarrhea, fatigue, nausea, peripheral neuropathy, and vomiting. Adverse events occurring in 10% or more of patients treated with pertuzumab include arthralgia, constipation, decreased appetite, dizziness, dry skin, dysgeusia, dyspnea, headache, increased lacrimation, insomnia, itching, mucosal inflammation, myalgia, nail disorders, nasopharyngitis, peripheral edema, paronychia, stomatitis, upper respiratory tract infections, and vomiting. Adverse reactions were reported less frequently after discontinuation of docetaxel treatment. See prescribing information for additional side effects.

Post-Marketing:

Tumor lysis syndrome (TLS).

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. If signs of an infusion reaction occur, slow or interrupt the infusion and treat appropriately. Monitor patients carefully until symptoms resolve. Discontinue immediately for a serious hypersensitivity reaction. Discontinue pertuzumab for a confirmed clinically significant decrease in left ventricular function. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity from concurrent antineoplastics. Treat hypersensitivity reactions with epinephrine, antihistamines, corticosteroids, bronchodilators, and oxygen. Resuscitate as indicated.

PHENOBARBITAL SODIUM

(fee-no-**BAR**-bih-tal **SO**-dee-um)
Luminal Sodium
Barbiturate
Sedative-hypnotic
Anticonvulsant
pH 8.5 to 10.5

USUAL DOSE

Pretreatment:

See Maternal/Child.

Use only enough medication to achieve the desired effect. May take up to 15 minutes to reach peak levels in the brain; guard against overdose and excessive respiratory depression.

Hypnotic:

100 to 325 mg.

Sedative:

30 to 120 mg/day in 2 or 3 divided doses (15 to 60 mg every 12 hours or 10 to 40 mg every 8 hours).

Anticonvulsant:

200 to 320 mg. May be repeated if necessary. Maximum dose usually does not exceed 600 mg.

Status epilepticus:

Loading dose:

10 to 20 mg/kg in single or divided doses. May give an additional 5 mg/kg every 15 to 30 minutes up to a maximum dose of 30 mg/kg.

Maintenance dose:

1 to 3 mg/kg/24 hr or 0.5 to 1.5 mg/kg every 12 hours.

PEDIATRIC DOSE

See comments under Usual Dose.

Preoperative sedation:

1 to 3 mg/kg of body weight 60 to 90 minutes before procedure.

Status epilepticus:

Loading dose:

15 to 18 mg/kg as a single dose or in divided doses. May give an additional 5 mg/kg every 15 to 30 minutes up to a maximum total dose of 30 mg/kg.

Maintenance dose:

Infants:

2.5 to 3 mg/kg every 12 hours.

Ages 1 to 5:

3 to 4 mg/kg every 12 hours.

Ages 6 to 12:

2 to 3 mg/kg every 12 hours.

Over 12 years of age:

0.5 to 1.5 mg/kg every 12 hours. Up to 12 mg/kg/24 hours has been used in maintenance doses.

NEONATAL DOSE

See comments under Usual Dose.

Status epilepticus:

Loading dose:

15 to 20 mg/kg as a single dose or in divided doses.

Maintenance dose:

1.5 to 2 mg/kg every 12 hours; may be increased to 2.5 mg/kg every 12 hours if needed. Therapeutic range is 15 to 40 mg/L. Because of its long half-life, it may take 2 to 3 weeks to reach steady-state levels.

DOSE ADJUSTMENTS

Reduce dose in impaired renal or hepatic function; usually required in the debilitated or elderly. ■ See Drug/Lab Interactions.

DILUTION

Sterile powder must be slowly diluted with SWFI. Use a minimum of 3 mL of diluent. Also available in sterile vials and tubexes. Best if further diluted up to 10 mL with SWFI. Solutions from powder form must be freshly prepared. Use only absolutely clear solutions. Discard powder or solution exposed to air for 30 minutes.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

60 mg or fraction thereof over 1 minute. Titrate slowly to desired effect. Rapid injection rate may cause symptoms of overdose (e.g., serious respiratory depression).

Status epilepticus:

A single loading dose over 10 to 15 minutes.

ACTIONS

A sedative, hypnotic barbiturate of long duration with potent anticonvulsant effects. Phenobarbital is a CNS depressant. Onset of action is prompt by the IV route and becomes rapidly more intense. Effects last from 6 to 10 hours. Will effectively depress the motor cortex with small doses. Pain perception is unimpaired. Rapidly absorbed by all body tissues and excreted in changed form in the urine. Excreted more readily in alkaline urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Prolonged sedation (medical and psychiatric). ■ Anticonvulsant.

CONTRAINDICATIONS

History of porphyria, impaired renal function, impaired hepatic function especially with any signs of hepatic coma, known hypersensitivity to barbiturates, previous addiction, severe respiratory depression including dyspnea, obstruction, or cor pulmonale.

PRECAUTIONS

IV route usually reserved for critical situations. ■ Use caution in elderly and debilitated patients and those with asthma, pulmonary disease, shock, and impaired renal or hepatic function. ■ Status epilepticus can occur from too-rapid withdrawal. ■ May be habit forming. Use caution in acute or chronic pain.

Monitor:

Keep patient under constant observation. Record vital signs every hour, or more often if indicated. ■ Maintain a patent airway. ■ Monitor hematopoietic, renal and hepatic systems in any extended therapy. ■ Treat the cause of a convulsion. ■ Keep equipment for artificial ventilation available. ■ Highly alkaline. Determine absolute patency of vein; use of large veins preferred to prevent thrombosis. Avoid extravasation. Intra-arterial injection will cause gangrene. ■ Monitor serum levels as indicated; the therapeutic range in adults is 20 to 40 mcg/mL (15 to 40 mcg/mL in pediatric patients). Because of its long half-life, it may take 2 to 3 weeks to reach steady-state levels. ■ See Drug/Lab Interactions.

Patient Education:

Avoid alcohol or other CNS depressants. May be habit forming. ■ May require alternate birth control.

Maternal/Child:

Category D: avoid pregnancy; will cause birth defects. ■ May cause drowsiness in the nursing infant. ■ See Precautions.

Elderly:

See Dose Adjustments and Precautions. ■ Often have increased sensitivity to barbiturates; may cause marked excitement, depression, confusion, and increased risk of barbiturate-induced hypothermia. ■ Consider age-related hepatic or renal impairment and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

Use extreme caution if any other **CNS depressants** have been given, such as alcohol, aminoglycoside antibiotics, narcotic analgesics, anesthetics, antidepressants, antihistamines, hypnotics, MAO inhibitors, phenothiazines, sedatives, tranquilizers. Potentiation with respiratory depression may occur. ■ Inhibits effectiveness of **corticosteroids, doxycycline, oral anticoagulants, oral contraceptives, propranolol, quinidine, and theophylline.** Capable of innumerable interactions with many drugs. ■ May increase orthostatic hypotension with **furosemide**. ■ Monitor **phenytoin, carbamazepine, valproic acid, and phenobarbital** levels when any combination of these drugs is used concurrently. ■ May decrease the pharmacologic effect of **vitamin D.** ■ May decrease plasma concentrations and effectiveness of **triazole antifungals**.

SIDE EFFECTS

Rarely occur with slow injection of average doses.

Average dose:

Depression, dermatitis, facial edema, fever, headache, hypotension, nausea, neonatal apnea, respiratory depression (hypoventilation), thrombocytopenic purpura, vertigo.

Overdose:

Apnea, coma, cough reflex depression, delirium, flat EEG (reversible unless hypoxic damage has occurred), hypotension, laryngospasm, lowered body temperature, pulmonary edema, renal shutdown, respiratory depression, sluggish or absent reflexes, stupor.

ANTIDOTE

Notify the physician of any side effects. Symptomatic and supportive treatment is most important in overdose. Maintain an adequate airway with artificial ventilation if indicated. Keep the patient warm. IV volume expanders and other IV fluids will help maintain adequate circulation. Diuretics may promote the elimination of the drug. Vasopressors will maintain BP.

PHENTOLAMINE MESYLATE

(fen-**TOLL**-ah-meen **MES**-ih-layt)
Regitine
Alpha-adrenergic blocking agent
Antihypertensive
Vasodilator
pH 4.5 to 6.5

USUAL DOSE

Preoperative:

5 mg 1 to 2 hours before surgery. If necessary during surgery, the same doses are administered as needed to control epinephrine intoxication.

Prevent necrosis caused by norepinephrine (Levophed):

Add 10 mg to each 1,000 mL of IV solution containing norepinephrine or dopamine.

Test dose for diagnosis of pheochromocytoma:

2.5 to 5 mg.

PEDIATRIC DOSE

Preoperative:

1 mg, 0.1 mg/kg of body weight, or 3 mg/M^2 1 to 2 hours before surgery. Repeat as indicated; see Usual Dose.

Prevent necrosis caused by norepinephrine (Levophed):

Add 0.1 to 0.2 mg/kg up to a maximum of 10 mg to each 1,000 mL of IV solution containing norepinephrine.

Test dose for diagnosis of pheochromocytoma:

1 mg.

DILUTION

Each 5 mg should be reconstituted with 1 mL of SWFI. May be further diluted with 5 to 10 mL of SWFI or NS. Use only freshly prepared solutions.

Storage:

Store below 40° C.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each 5 mg or fraction thereof over 1 minute.

Test dose:

Inject rapidly after pressor response to venipuncture has subsided.

ACTIONS

An alpha-blocking agent that competitively antagonizes endogenous and exogenous alpha agents (e.g., epinephrine and norepinephrine). Has positive chronotropic and inotropic effects on cardiac muscle, as well as vasodilator effects on vascular smooth muscle. Onset of action is prompt. Half-life is approximately 19 minutes. Metabolic fate is undetermined.

INDICATIONS AND USES

Prevention and treatment of hypertensive episodes of pheochromocytoma preoperatively and during surgery. ■ Prevention and treatment of necrosis and sloughing occurring with dopamine and norepinephrine (Levophed). ■ Diagnosis of pheochromocytoma by the phentolamine blocking test.

CONTRAINDICATIONS

Coronary artery disease, coronary insufficiency, hypersensitivity to phentolamine, myocardial infarction (previous or present).

PRECAUTIONS

Use caution in gastritis or peptic ulcer disease. ■ Use care in the presence of any arrhythmia. It is preferable to have a normal sinus rhythm. ■ MI, cerebrovascular spasm, and cerebrovascular occlusion have occurred following administration, usually in association with marked hypotensive episodes. ■ For diagnosis of pheochromocytoma, urinary tests such as vanillylmandelic acid (VMA) are safer and more accurate. Phentolamine is used only when absolutely necessary. Specific procedure must be followed. Consult with physician and pharmacist.

Monitor:

Monitor vital signs every 2 minutes.

Maternal/Child:

Category C: safety for use during pregnancy and breast-feeding not established. Use with extreme caution and only when clearly indicated.

Elderly:

Risk of phentolamine-induced hypothermia may be increased.

DRUG/LAB INTERACTIONS

Antagonizes effects of **epinephrine** and **ephedrine.**

SIDE EFFECTS

Abdominal pain, diarrhea, dizziness, hypotension, nasal stuffiness, nausea, tachycardia, tingling of skin, weakness, vomiting.

Major:

Cardiac arrhythmias, cerebrovascular occlusion, cerebrovascular spasm, hypotension (severe), myocardial infarction, shock, tachycardia, vomiting under anesthesia.

ANTIDOTE

For minor side effects, notify the physician. If symptoms progress or any major side effect occurs, discontinue drug and notify the physician immediately. Elevation of legs, volume expanders (e.g., albumin, hetastarch), and administration of norepinephrine are recommended for treatment of hypotension. Do not use epinephrine. Maintain the patient as indicated. If tachycardia or cardiac arrhythmias occur, defer use of digoxin if possible until rhythm returns to normal.

PHENYLEPHRINE HYDROCHLORIDE

(fen-ill-**EF**-rin hy-droh-**KLOR**-eyed)
Neo-Synephrine, Vazculep

Vasopressor
pH 3 to 6.5

USUAL DOSE

Perioperative setting:

Bolus:

40 to 100 mcg by IV bolus administration. May repeat every 1 to 2 minutes as needed, not to exceed a total dose of 200 mcg.

A second manufacturer lists an initial bolus of 50 to 100 mcg with a range of 50 to 250 mcg.

Continuous infusion:

If BP is below target goal, begin a continuous infusion of 10 to 35 mcg/min, not to exceed 200 mcg/min.

A second manufacturer lists a rate of 0.5 to 1.4 mcg/kg/min. Titrate to blood pressure goal.

Septic or other vasodilatory shock *(no longer recommended for routine use for this indication)*:

Do not administer a bolus. Begin with a continuous infusion of 0.5 to 6 mcg/kg/min. Titrate to blood pressure goal. Doses above 6 mcg/kg/min do not show a significant incremental increase in blood pressure.

Another source recommends:

Begin infusion at 100 to 180 mcg/min (0.1 to 0.18 mg/min) until BP is stabilized at a low normal for specific individual. Maintain with 40 to 60 mcg/min (0.04 to 0.06 mg/min). Titrate to desired effect.

DOSE ADJUSTMENTS

Patients with liver cirrhosis (Child-Pugh Class B and Class C) may have decreased responsiveness to phenylephrine. Higher-end doses may be required to achieve BP goal. ■ Patients with end-stage renal disease may have increased responsiveness to phenylephrine. Initiate dosing at lower end of dosing range.

DILUTION

IV bolus:

Dilute 10 mg (1 mL of a 10 mg/mL solution) with 99 mL of NS or D5W to provide a final concentration of 100 mcg/mL. Withdraw an appropriate dose from this solution prior to bolus administration.

Infusion:

Dilute 10 mg in 500 mL of NS or D5W to provide a final concentration of 20 mcg/mL.

Storage:

Store unopened vials at CRT in carton. Protect from light. Diluted solution should not be held for more than 4 hours at RT or for more than 24 hours under refrigeration. Discard any unused portion.

COMPATIBILITY

Compatibility information not available from manufacturer. Other source suggests specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Administer by slow injection.

Infusion:

See Usual Dose. Titrate to maintain individual's low-normal BP. Use an infusion pump or microdrip (60 gtt/mL) to administer. Central line preferred.

ACTIONS

An alpha-1 adrenergic receptor agonist. Interacts with the receptors on the vascular smooth muscle cells, resulting in vasoconstriction. Increases in systolic blood pressure, diastolic blood pressure, mean arterial blood pressure, and total peripheral vascular resistance are observed within minutes of administration. As blood pressure increases, vagal activity also increases, resulting in a reflex bradycardia. Active on most vascular beds, including renal, pulmonary, and splanchnic arteries. Duration of effect is 15 to 20 minutes. Terminal half-life is 2.5 hours. Metabolized primarily by monoamine oxidase and sulfotransferase. Excreted in urine, primarily as inactive metabolites.

INDICATIONS AND USES

Treatment of clinically important hypotension resulting primarily from vasodilation in settings such as septic shock or anesthesia. *(No longer recommended for routine use in treatment of hypotension related to septic shock.)*

CONTRAINDICATIONS

Hypersensitivity to phenylephrine or any of its components.

PRECAUTIONS

Intravascular volume depletion should be corrected. ■ Correct acidosis. Acidosis may reduce effectiveness of phenylephrine. ■ Because of its pressor effects, phenylephrine can precipitate angina in patients with severe arteriosclerosis or history of angina, exacerbate underlying heart failure, and increase pulmonary arterial pressure. ■ Avoid extravasation. Can cause necrosis or sloughing of tissue. ■ Can cause peripheral and visceral vasoconstriction and ischemia to vital organs, particularly in patients with extensive peripheral vascular disease. ■ Can cause severe bradycardia and decreased cardiac output. ■ Can increase the need for renal replacement therapy in patients with septic shock. ■ The pressor response to adrenergic drugs, including phenylephrine, can be increased in patients with autonomic dysfunction, such as may occur with spinal cord injuries. ■ Contains bisulfites; use caution in allergic individuals. ■ See Drug/Lab Interactions.

Monitor:

Monitor vital signs. ■ Check infusion site for free flow. Discontinue IV administration if vein infiltrates or is thrombosed. ■ Monitor renal function. ■ See Precautions, Drug/Lab Interactions.

Maternal/Child:

Category C: safety for use in pregnancy or breast-feeding not established. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

See Precautions; may have increased sensitivity to effects.

DRUG/LAB INTERACTIONS

Oxytocic drugs (e.g., oxytocin) potentiate the increasing blood pressure effects of sympathomimetic pressor amines, including phenylephrine, with the potential for hemorrhagic stroke. ■ The pressor effect of phenylephrine is also increased in patients receiving **MAO inhibitors, tricyclic antidepressants, angiotensin, aldosterone, atropine, steroids, norepinephrine transporter inhibitors** (e.g., atomoxetine), **or ergot alkaloids**. ■ The pressor effect of phenylephrine is decreased in patients receiving **alpha-adrenergic antagonists, phosphodiesterase type 5 inhibitors, mixed alpha- and beta-receptor antagonists** (e.g., labetalol, carvedilol), **calcium channel blockers, benzodiazepines, ACE inhibitors, or centrally acting sympatholytic agents**.

SIDE EFFECTS

The most common side effects are headache, nausea, and vomiting. Other reported side effects include arrhythmias, blurred vision, chest pain, diaphoresis, dyspnea, epigastric pain, extravasation, fullness of head, hypersensitivity (sulfite sensitivity), hypertension, hypertensive crisis, ischemia, lower cardiac output, neck pain, nervousness, paresthesia, pruritus, pulmonary edema, rales, reflexive bradycardia, skin blanching, skin necrosis with extravasation, and tremor.

ANTIDOTE

To prevent sloughing and necrosis in areas of extravasation, with a fine hypodermic needle inject 5 to 10 mg of phentolamine diluted in 10 to 15 mL of NS liberally throughout the tissue in the extravasated area. Treatment should be started as soon as extravasation is recognized. Notify the physician of all side effects. IM injection may be preferable. Treat hypertension with phentolamine. Treat cardiac arrhythmias as indicated. Treat bradycardia with atropine. Resuscitate as necessary.

PHENYTOIN SODIUM BBW

(**FEN**-ih-toyn **SO**-dee-um)
Dilantin
Hydantoin
Anticonvulsant
pH 12

USUAL DOSE

Pretreatment:

See Maternal/Child.

In all situations, transfer to oral therapy as soon as practical. See Precautions and Monitor. Treatment with phenytoin can be initiated either with a loading dose or an infusion.

Status epilepticus, anticonvulsant:

A ***loading dose*** of 10 to 15 mg/kg. One source recommends not exceeding a total dose of 1.5 Gm in 24 hours. Lethal dose estimated at 2 to 5 Gm. Another source suggests that 15 to 20 mg/kg is generally recommended. Follow with ***maintenance doses*** of 100 mg every 6 to 8 hours. Adjust dose based on phenytoin levels; see Monitor. Other measures, including concomitant administration of an IV benzodiazepine (such as diazepam) or an IV short-acting barbiturate, will usually be necessary for rapid control of seizures because of the required slow rate of administration of phenytoin. If seizure is not terminated, consider other anticonvulsants, barbiturates, or anesthesia.

Non-emergent loading and maintenance dosing:

10 to 15 mg/kg as a ***loading dose*** followed by a ***maintenance dose*** of oral or IV phenytoin every 6 to 8 hours.

PEDIATRIC DOSE

Status epilepticus, anticonvulsant:

15 to 20 mg/kg as a ***loading dose.*** Follow with a ***maintenance dose for age*** (listed below):

Neonates:

Begin with 5 mg/kg/24 hr in equally divided doses every 12 hours. Range is 4 to 8 mg/kg/24 hr in divided doses every 8 or 12 hours (2 to 4 mg/kg every 12 hours or 1.33 to 2.67 mg/kg every 8 hours).

Infants and other pediatric patients:

Begin with 5 mg/kg/24 hr in equally divided doses every 8 to 12 hours (2.5 mg/kg every 12 hours or 1.67 mg/kg every 8 hours). Range varies according to age:

6 months to 3 years:

8 to 10 mg/kg/24 hr (4 to 5 mg/kg every 12 hours or 2.67 to 3.33 mg/kg every 8 hours).

4 to 6 years:

7.5 to 9 mg/kg/24 hr (3.75 to 4.5 mg/kg every 12 hours or 2.5 to 3 mg/kg every 8 hours).

7 to 9 years:

7 to 8 mg/kg/24 hr (3.5 to 4 mg/kg every 12 hours or 2.3 to 2.6 mg/kg every 8 hours).

10 to 16 years:

6 to 7 mg/kg/24 hr (3 to 3.5 mg/kg every 12 hours or 2 to 2.3 mg/kg every 8 hours).

DOSE ADJUSTMENTS

After the initial maintenance dose, subsequent maintenance doses should be individualized by monitoring serum levels of phenytoin to achieve a target therapeutic concentration. ■ Lower or less frequent dosing and a slower rate of administration may be required in elderly patients. ■ Use caution, lower dose, and slower rate of administration in seriously ill patients and cachectic patients. ■ Lower doses may also be required in patients with renal or hepatic disease or in those with hypoalbuminemia. Monitoring of unbound (free) phenytoin concentrations may be a better dosing guide. ■ Dose adjustment may be needed when switching between the sodium salt formulations (e.g., injection and capsules) and the free acid forms (e.g., suspension and infatabs). The free acid form contains approximately 8% more drug than the sodium salt form. ■ See Drug/Lab Interactions.

DILUTION

Available in 100- or 250-mg single-dose ampules or vials and in 100-mg single-dose syringes. After verifying patency, may be administered directly into a large peripheral or central vein through a large-gauge catheter. Alternately, may be further diluted in NS to a concentration of no less than 5 mg/mL and administered as an infusion. Use solution only when completely dissolved and clear.

Filters:

Manufacturer recommends use of an in-line filter (0.22 to 0.55 microns) when administered as an infusion.

Storage:

Store between 15° and 30° C (59° and 86° F). Infusion solutions should be administered immediately after preparation and must be completed within 1 to 4 hours. Do not refrigerate infusion solutions.

COMPATIBILITY

Manufacturer recommends not adding to IV solutions other than NS or mixing with other medications and states that “the addition of phenytoin to dextrose or dextrose-containing solutions will result in precipitation.” Always flush line with NS before and after administration of any other drug through the same IV line. See Dilution.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Because of the risk of local toxicity, IV phenytoin should be administered directly into a large peripheral or central vein through a large-gauge catheter. Before administration, the patency of the IV should be tested with a sterile saline flush. Follow the administration of phenytoin with a saline flush to avoid local venous irritation due to the alkalinity of the solution. In nonemergent situations, slower rates of administration should be used.

Adults:

Administer slowly at a rate of 25 to 50 mg or fraction thereof over 1 minute.
Do not exceed 50 mg/min.

Pediatric patients:

Do not exceed 1 to 3 mg/kg/min (or 50 mg/min, whichever is slower). Another source suggests 0.5 mg/kg/min in neonates or 1 mg/kg/min in infants and other pediatric patients not to exceed 50 mg/min.

Elderly:

Limit rate to 25 mg/min.

Infusion:

Should be completed within 1 to 4 hours. Do not exceed 25 to 50 mg/min rate. Best if piggybacked to a **compatible** primary IV so phenytoin can be discontinued if side effects occur, but IV can be kept open.

ACTIONS

An anticonvulsant, chemically related to barbiturates. Selectively stabilizes seizure threshold and depresses seizure activity in the motor cortex. Mechanism of action may be due to increasing efflux or decreasing influx of sodium ions across the cell membrane during generation of the action potential. Effective control in emergency treatment of seizures may take 15 to 20 minutes because of rate of injection required. Highly protein bound. Metabolized by cytochrome P_{450} enzymes CYP2C9 and CYP2C19. Most of the drug is excreted in the bile as inactive metabolites. Urinary excretion of phenytoin and its metabolites occurs by glomerular filtration and tubular secretion. Half-life ranges from 10 to 15 hours. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of generalized tonic-clonic status epilepticus and prevention and treatment of seizures during neurosurgery. Parenteral phenytoin should be used only when oral phenytoin administration is not possible.

CONTRAINDICATIONS

Known hypersensitivity to phenytoin or other hydantoin products. ■ Bradycardia; sinoatrial, second-, or third-degree AV heart block; Adams-Stokes syndrome. ■ A history of prior acute hepatotoxicity attributable to phenytoin. ■ Coadministration with delavirdine (Rescriptor); see Drug/Lab Interactions.

PRECAUTIONS

Discontinue immediately for hypersensitivity reactions; with caution, substitute a nonhydantoin anticonvulsant. When substituting a new anticonvulsant, consideration should be given to avoiding structurally related drugs such as carboxamides (e.g., carbamazepine), barbiturates, succinimides, and oxazolidinediones (e.g., trimethadione). ■ Angioedema has been reported. ■ Abrupt withdrawal may cause increased seizure activity. Gradually reduce dose, discontinue, or substitute alternative antiepileptic agents if possible. ■ Severe hypotension and cardiac arrhythmias have occurred with rapid infusion. Risk increases with increased rates, but adverse cardiac events have been reported at or below the recommended infusion rates. Cardiac arrhythmias have included bradycardia, heart block, ventricular tachycardia, and ventricular fibrillation and have resulted in asystole, cardiac arrest, and death. Severe complications are most commonly encountered in critically ill patients, elderly patients, and patients with hypotension and severe myocardial insufficiency. Careful cardiac monitoring is required during and after IV administration. Because of the risks of cardiac and local toxicity associated with IV phenytoin, oral phenytoin should be used whenever possible. ■ Use caution with low serum albumin level, and adjust dose as indicated. Phenytoin is highly bound to serum protein (approximately 80% to 90% or more), and a reduced albumin causes an increase in free drug availability. ■ Drug reaction with eosinophilia and systemic symptoms (DRESS), also known as multiorgan hypersensitivity, has been reported. Usually presents with fever, rash, lymphadenopathy, and/or facial swelling in association with other organ system involvement such as hepatitis, nephritis, hematologic abnormalities, myocarditis, or myositis. Eosinophilia is often present. Deaths have been reported. Discontinue therapy if an alternative etiology for S/S cannot be established. ■ Severe cutaneous adverse reactions (SCARs) have been reported, including toxic epidermal necrolysis (TEN), Stevens-Johnson syndrome (SJS), acute generalized exanthematous pustulosis (AGEP), and DRESS. Deaths have occurred. Onset of symptoms is usually within 28 days but may occur later. Discontinue phenytoin at the first sign of a rash unless the rash is clearly not drug related. If a rash develops, the patient should be evaluated for S/S of SCARs. ■ Selected patients of Asian ancestry with a specific human leukocyte antigen allele (HLA-B*1502) may have an increased risk of serious skin reactions (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis) from phenytoin therapy. ■ Cases of acute hepatotoxicity, including hepatic failure, have been reported. These events may be part of the spectrum of DRESS or may occur in isolation. Reactions have included elevated liver function tests, eosinophilia, hepatomegaly, jaundice, and leukocytosis. Discontinue immediately and substitute alternative anticonvulsant therapy. ■ Hematopoietic complications, some fatal, have been reported (e.g., agranulocytosis, granulocytopenia, leukopenia, thrombocytopenia, or pancytopenia with or without bone marrow suppression). ■ Some reports suggest a relationship between phenytoin and the development of lymphadenopathy (local or generalized), including benign lymph node hyperplasia, pseudolymphoma, lymphoma, and Hodgkin disease. Lymph node involvement may occur with or without S/S resembling DRESS; see Monitor. ■ Local toxicity, including purple glove syndrome (edema, discoloration, and pain distal to the injection site), has occurred and may or may not be associated with extravasation. Irritation may range from slight tenderness to extensive necrosis and sloughing. ■ Inhibits insulin release and may increase serum glucose; monitoring indicated in patients with diabetes. ■ A small percentage of patients may be slow metabolizers of phenytoin. This appears to be genetically determined. If early signs of dose-related CNS toxicity develop, obtain serum levels immediately. ■ Not effective for absence seizures; combined therapy is required if both conditions are present. ■ Not indicated for seizures due to hypoglycemia or other metabolic causes. ■ Use with caution in patients with porphyria. Phenytoin may exacerbate this disease. ■ Antiepileptic drugs (AEDs) increase the risk of suicidal thoughts or behavior in patients taking these drugs for any indication. Patients treated with any AED for any indication should be monitored for the emergence or worsening of depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior. Some psychotic symptoms and/or behavioral changes resolved without intervention. Others required dose reduction or discontinuation of the antiepileptic agent.

Monitor:

Narrow margin of error between therapeutic and toxic dose. Plasma levels above 10 mcg/mL usually control seizure activity. The acceptable range is 10 to 20 mcg/mL. ■ Consider monitoring free phenytoin levels in patients with hypoalbuminemia or renal or hepatic insufficiency (therapeutic range is 1 to 2 mcg/mL); fraction of unbound phenytoin is increased. ■ Toxicity usually begins with nystagmus and may be seen at levels less than 20 mcg/mL. Serum levels sustained above the optimum range may produce confusional states referred to as delirium, psychosis, encephalopathy or, rarely, irreversible cerebellar dysfunction and/or cerebellar atrophy. Observe patient closely for signs of CNS side effects. At the first sign of acute toxicity, plasma levels are recommended. Reduce dose if levels are elevated. If symptoms persist, discontinuation of therapy is recommended. ■ Periodic monitoring of CBC, platelets, albumin, urinalysis, and hepatic and renal function is recommended. ■ Monitor ECG, BP, and respiratory status carefully during and after administration. ■ Closely monitor patients who are gravely ill, have impaired liver function, or are elderly. May show early signs of toxicity. ■ In all cases of lymphadenopathy, follow-up observation for an extended period is indicated, and alternative anticonvulsant therapy should be strongly considered. ■ Observation of patient symptoms and evaluation of effectiveness of all medications is imperative. ■ Monitor for S/S of hypersensitivity reactions. ■ Observe for rash and discontinue if one appears; see Precautions. ■ Monitor for symptoms of angioedema (e.g., facial, perioral or upper airway swelling). ■ Determine absolute patency of vein. Avoid extravasation. Very alkaline; follow each injection with sterile NS to reduce local venous irritation; see Rate of Administration. ■ Patients maintained with phenytoin should be given a dose the morning of surgery to maintain adequate serum levels. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

May increase the risk of suicidal thoughts and behavior. Promptly report emergence or worsening of S/S of depression, any unusual changes in mood or behavior, or thoughts about self-harm. ■ Effective birth control required for women of childbearing potential who are not planning a pregnancy. Hormonal contraceptive efficacy may be decreased; see Maternal/Child. ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry. ■ Do not discontinue phenytoin without consulting health care provider. ■ Report S/S of dermatologic, hematologic, hepatic, or hypersensitivity reactions (e.g., anorexia, easy bruising, facial swelling, fever, jaundice, lymphadenopathy, mouth ulcers, nausea and vomiting, petechial or purpuric hemorrhage, rash, sore throat) or angioedema (e.g., facial, perioral, or upper airway swelling). ■ Numerous drug interactions possible. Review all medications and alcohol use with provider. ■ May cause increase in blood sugar. ■ Good dental hygiene required to minimize development of gingival hyperplasia. ■ May cause decreased coordination, dizziness, gait disturbance, and somnolence. Use caution when performing tasks that require alertness.

Maternal/Child:

Avoid pregnancy. May cause fetal harm when administered to a pregnant woman. Prenatal exposure to phenytoin may increase the risk for congenital malformations and other adverse developmental outcomes; see manufacturer’s prescribing information. Consider risks versus benefit. ■ An increase in seizure frequency may occur because of alterations in phenytoin kinetics and decreased serum concentrations in pregnant women; may necessitate periodic monitoring of serum levels. Because of potential changes in protein binding, monitoring of phenytoin serum levels should be based on the unbound fraction. ■ Newborns whose mothers received phenytoin during pregnancy may develop a life-threatening bleeding disorder that can be prevented by giving vitamin K to the mother before delivery and to the neonate after birth. ■ Phenytoin is secreted in breast milk. Consider risk of infant exposure versus benefit of breast-feeding to the infant and benefit of treatment to the mother.

Elderly:

See Dose Adjustments and Rate of Administration. ■ Clearance tends to decrease with increasing age; lower or less frequent dosing may be required. ■ Low serum albumin causing a decrease in protein binding may result in increased sensitivity to phenytoin.

DRUG/LAB INTERACTIONS

Interactions are numerous and potentially life threatening. Review of drug profile by pharmacist imperative. ■ Phenytoin is highly protein bound and is prone to competitive displacement. ■ Phenytoin is metabolized by CYP2C9 and CYP2C19 and is particularly susceptible to inhibitory drug interactions because it is subject to saturable metabolism. Inhibition of metabolism may produce significant increases in circulating phenytoin concentrations, increasing the risk of toxicity. ■ Coadministration with **delavirdine** is contraindicated. Has potential for loss of virologic response and possible resistance to delavirdine or to the class of nonnucleoside reverse transcriptase inhibitors. ■ Serum levels may be increased by **alcohol** (acute ingestion), **amiodarone, antiepileptic agents, azole antifungals, capecitabine, chloramphenicol, chlordiazepoxide, disulfiram, estrogens, fluorouracil, fluoxetine, fluvastatin, fluvoxamine**, **H_2 antagonists**, **isoniazid, methylphenidate, omeprazole, phenothiazines, salicylates, sertraline, sulfonamides, trazodone, and warfarin**. ■ Serum levels and effectiveness may be decreased by **antineoplastics, carbamazepine, chronic alcohol abuse, diazepam, diazoxide, folic acid, fosamprenavir, nelfinavir, reserpine, rifampin, ritonavir, St. John's wort, theophylline, and vigabatrin**. ■ Phenytoin serum levels may be increased or decreased by **phenobarbital, valproate sodium, and valproic acid**. Similarly, phenytoin may unpredictably affect the levels and efficacy of these drugs. ■ The addition of withdrawal of drugs while patients are undergoing phenytoin therapy may require an adjustment of the phenytoin dose. ■ Phenytoin will inhibit the effects of **azole antifungals, corticosteroids, doxycycline, estrogens, furosemide, irinotecan, oral contraceptives, paclitaxel, paroxetine, quinidine, rifampin, sertraline, teniposide, theophylline, and vitamin D**. Dose adjustment of these agents may be indicated. ■ Because phenytoin is a potent enzyme inducer, it decreases plasma concentrations of **albendazole, HIV antivirals, antiepileptic agents, atorvastatin, chlorpropamide, clozapine, cyclosporine, digoxin, disopyramide, fluvastatin, folic acid, methadone, mexiletine, nifedipine, nimodipine, nisoldipine, praziquantel, quetiapine, simvastatin, and verapamil**. Adjust doses of these agents as indicated. ■ Phenytoin when given with **fosamprenavir** alone may decrease the concentration of **amprenavir**, the active metabolite. Phenytoin when given with the combination of **fosamprenavir and ritonavir** may increase the concentration of **amprenavir**. ■ May increase or decrease PT/INR responses when coadministered with **warfarin**. ■ Alters **some clinical laboratory tests** (e.g., may decrease T_3 and T_4; may increase glucose, alkaline phosphatase, GGT, and TSH; and may produce low results in dexamethasone or metyrapone tests).

SIDE EFFECTS

The most common adverse reactions are nervous system reactions, including ataxia, decreased coordination, mental confusion, nystagmus, slurred speech, and somnolence. Other reported reactions include altered taste sensation, constipation, dizziness, drowsiness, dyskinesias, fever, headache, hyperplasia of gums, insomnia, local irritation/toxicity, nausea, nervousness, paresthesia, skin eruptions, tremors, vertigo, visual disturbances, and vomiting.

Serious adverse reactions, including acute hepatic failure, bradycardia, cardiac arrest, cardiovascular collapse, CNS depression, dermatologic reactions (including local toxicity, Stevens-Johnson syndrome, and toxic epidermal necrolysis), DRESS, heart block, hematopoietic complications, hypersensitivity reactions (including anaphylaxis [rare]), hypotension, lymphadenopathy, Peyronie's disease, respiratory arrest, tonic seizures, toxic hepatitis, and ventricular fibrillation, have been reported. Psychotic symptoms, including aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies, have occurred with antiepileptic agents. Cerebellar atrophy has been reported and appears more likely in settings of elevated phenytoin levels and/or long-term phenytoin use.

Overdose:

Ataxia, blurred vision, coma, dysarthria, hyperreflexia, hypotension, irreversible cerebellar dysfunction and atrophy, lethargy, nausea, nystagmus, slurred speech, tremor, and vomiting. Death is caused by respiratory and circulatory depression.

ANTIDOTE

Notify the physician of any side effects. If minor symptoms progress or any major side effect occurs, discontinue the drug and notify the physician; see Precautions. Obtain serum plasma levels at first signs of toxicity. If serum levels are excessive, symptoms persist, or major side effects appear, discontinue phenytoin and notify physician. Treat symptomatically, maintain a patent airway, and resuscitate as necessary. Discontinue phenytoin at the first sign of a rash unless the rash is clearly not drug related. If TEN or SJS is suspected, do not rechallenge; consider alternate therapy. Discontinue immediately if symptoms of angioedema develop. Evaluate for multiorgan hypersensitivity reactions (DRESS). Cardiovascular toxicity, including hypotension or cardiac arrhythmias, may respond to a decrease in infusion rate. Decrease rate or discontinue infusion for severe hypotension or cardiac arrhythmias. Local toxicity (purple glove syndrome) may resolve spontaneously. Hemodialysis may be useful in overdose.

PHOSPHATE

(**FOS**-fayt)
Potassium Phosphate, Sodium Phosphate
Electrolyte replenisher
Antihypophosphatemic
pH 5 to 7.8

USUAL DOSE

Dependent on individual needs of the patient.

TPN, adults and pediatric patients:

10 to 15 mM (310 to 465 mg) of phosphorus/liter of TPN solution should maintain normal serum phosphate. Larger amounts may be required. 1 mM equals 31 mg.

Acute hypophosphatemia:

Adults and pediatric patients:

0.08 to 0.32 mM/kg of body weight as a ***loading dose*** equally distributed over 6 hours. ***Maintain pediatric patients*** with 0.5 to 1.5 mM/kg/24 hr. ***Maintain adults*** with 48.4 to 64.5 mM/24 hr.

INFANT DOSE

Infants receiving TPN:

1.5 to 2 mM/kg of body weight/day.

DOSE ADJUSTMENTS

Lower-end initial doses may be indicated in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Must be diluted in a larger volume of suitable IV solution and given as an infusion. Soluble in most commonly used IV solutions (see chart on inside back cover) except protein hydrolysate. Mix thoroughly. See Compatibility.

COMPATIBILITY

All Formulations

Mix thoroughly after each addition of supposedly **compatible** drugs or solutions. TPN solutions requiring the addition of phosphates and calcium salts must be mixed by the pharmacist to avoid a precipitate of calcium phosphate. Specific amounts, calculations, order, and temperature (precipitate forms more readily at room temperature) are required. Deaths have been reported.

Potassium Phosphate

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

Sodium Phosphate

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A usual dose is usually equally distributed over 6 hours. Other sources suggest administering up to 15 mM over 2 hours, up to 30 mM over 4 hours, and up to 45 mM over 6 hours. Potassium phosphate will be further limited by the maximum rate for potassium. Consider sodium/potassium content. Infuse slowly. Rapid infusion may cause phosphate or potassium intoxication. Serum calcium may be reduced rapidly, causing hypocalcemic tetany.

ACTIONS

Involved in bone deposition. Helps to maintain calcium levels, has a buffering effect on acid-base equilibrium, and influences renal excretion of the hydrogen ion. Normal levels in adults, 3 to 4.5 mg/dL of serum; in pediatric patients, 4 to 7 mg/dL. Excreted in urine.

INDICATIONS AND USES

To prevent or correct hypophosphatemia in patients with restricted or no oral intake.

CONTRAINDICATIONS

Any disease with high phosphate or low calcium levels, hyperkalemia (potassium phosphate), hypernatremia (sodium phosphate).

PRECAUTIONS

Rapid infusion may cause phosphate, sodium, or potassium intoxication. Serum calcium may be reduced, rapidly causing hypocalcemic tetany. ■ Use sodium phosphate with caution in renal impairment, cirrhosis, cardiac failure, or any edematous, sodium-retaining state. ■ Use potassium phosphate with caution in cardiac disease, renal disease, and digitalized patients. ■ See Compatibility.

Monitor:

Monitor serum calcium, potassium, phosphate, chlorides, and sodium. Discontinue when serum phosphate exceeds 2 mg/dL. ■ See Drug/Lab Interactions.

Maternal/Child:

Category C: safety for use in pregnancy not established.

Elderly:

Differences in response between elderly and younger patients have not been identified. Lower-end initial doses may be appropriate in the elderly; see Dose Adjustments.

DRUG/LAB INTERACTIONS

May cause hyperkalemia with **potassium-sparing diuretics** (e.g., amiloride) **or angiotensin-converting enzyme inhibitors**.

SIDE EFFECTS

Elevated phosphates, reduced calcium levels and hypocalcemic tetany, elevated potassium levels causing cardiac arrhythmias, flaccid paralysis, heaviness of the legs, hypotension, listlessness, mental confusion, paresthesia of the extremities.

ANTIDOTE

For any side effect, discontinue the drug and notify the physician. Restore serum calcium with calcium gluconate or chloride. Shift potassium from serum to cells with 150 mL of 10% to 20% dextrose with 10 units regular insulin for each 20 Gm dextrose at 300 to 500 mL/hr. Correct acidosis with sodium bicarbonate. Reduce sodium by restriction, diuretics, or hemodialysis. Resuscitate as necessary.

PHYSOSTIGMINE SALICYLATE

(fye-zoh-**STIG**-meen sah-**LIS**-ah-layt)
Cholinergic
Cholinesterase inhibitor
Antidote
pH 5.8

USUAL DOSE

Postanesthesia:

0.5 to 1 mg initially. Repeat at 10- to 30-minute intervals until desired results obtained.

Anticholinergic toxicity:

0.5 to 2 mg initially. 1 to 4 mg may be repeated as necessary as life-threatening signs recur (arrhythmias, convulsions, deep coma). Maximum dose is 4 mg in 30 minutes.

PEDIATRIC DOSE

To be used in life-threatening situations only. 0.02 mg/kg/dose. May be repeated at 5- to 10-minute intervals only if toxic effects persist and there is no sign of cholinergic effects. Maximum total dose is 2 mg. See Maternal/Child.

DILUTION

May be given undiluted. Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Rapid IV administration may cause bradycardia, hypersalivation, respiratory distress, and convulsions.

1 mg or fraction thereof over 1 to 3 minutes.

Pediatric rate:

0.5 mg or fraction thereof over at least 1 minute.

ACTIONS

An extract of *Physostigma venenosum* seeds. It inhibits the destructive action of acetylcholinesterase and prolongs and exaggerates the effects of acetylcholine. Stimulates parasympathetic nerve stimulation (pupil contraction, increased intestinal musculature tonus, bronchial constriction, salivary and sweat gland stimulation). Does enter the CNS. Onset of action occurs in 5 minutes and lasts about 1 hour. Rapidly hydrolyzed by cholinesterases.

INDICATIONS AND USES

To reverse CNS toxic effects caused by drugs capable of producing anticholinergic poisoning (e.g., atropine), other anticholinergic/antispasmodic agents, anticholinergic antiparkinson agents, and tricyclic antidepressants.

Unlabeled uses:

Treatment of delirium tremens.

CONTRAINDICATIONS

Asthma, cardiovascular disease, diabetes, gangrene, mechanical obstruction of the intestines or urogenital tract, vagotonic states, patients receiving choline esters, depolarizing neuromuscular blocking agents (succinylcholine), or tricyclic antidepressants.

PRECAUTIONS

Rapid IV administration may cause bradycardia, hypersalivation, respiratory distress, and convulsions. ■ Contains bisulfites; use caution in allergic individuals.

Monitor:

Atropine must always be available. ■ Monitor vital signs. ■ See Drug/Lab Interactions.

Maternal/Child:

Safety for use in pregnancy and breast-feeding not established. ■ Has caused muscular weakness in neonates of mothers treated with other cholinesterase inhibitors for myasthenia gravis. ■ May contain benzyl alcohol; do not use in neonates.

DRUG/LAB INTERACTIONS

Potentiates **succinylcholine** and **other choline esters** (e.g., bethanechol). ■ May antagonize CNS depressant effects of **diazepam**. ■ May cause serious complications, including death, with **tricyclic antidepressants**.

SIDE EFFECTS

Anxiety, bradycardia, cholinergic crisis (overdose), coma, convulsions, defecation, delirium, disorientation, emesis, hallucinations, hyperactivity, hypersalivation, hypersensitivity, nausea, respiratory distress, salivation, seizures, sweating, urination.

ANTIDOTE

Keep physician informed of side effects. For excessive nausea or sweating, reduce dose. Discontinue drug for bradycardia; convulsions; excessive defecation, emesis, salivation, or urination; or respiratory distress. Treat cholinergic side effects (e.g., arrhythmias, bronchoconstriction) or hypersensitivity with the specific antagonist atropine sulfate in doses of 0.6 mg IV. May be repeated every 3 to 10 minutes. Endotracheal intubation or tracheostomy are considered prophylactic in anesthesia or crisis. Artificial ventilation, oxygen therapy, cardiac monitoring, adequate suctioning, and treatment of shock or convulsions must be instituted and maintained as necessary.

PHYTONADIONE BBW

(fye-toe-nah-**DYE**-ohn)
Vitamin K_1
Vitamin (prothrombinogenic)
Antidote
Antihemorrhagic
pH 5 to 7

USUAL DOSE

Should be given by the SC or oral route whenever possible; IM or IV administration has caused severe reactions and death; see Precautions.

Vitamin K deficiency:

2.5 to 10 mg/dose times 1 dose.

Anticoagulant-induced (warfarin or dicumarol) hypoprothrombinemia:

2.5 to 10 mg or more. Doses up to 25 mg and, rarely, 50 mg may be needed. May repeat in 6 to 8 hours if initial response is not adequate. Doses as low as 1 to 2 mg may be effective. Use the smallest dose that achieves effective results to prevent clotting hazards. Dosing recommendations based on INR and the presence or absence of bleeding are available in the medical literature.

Hypoprothrombinemia from other causes:

2.5 to 25 mg or more (rarely 50 mg) depending on the severity of the deficiency and the response obtained. Modify subsequent dosage (amount and frequency) based on the INR or clinical condition.

PEDIATRIC DOSE

See Usual Dose, Precautions, and Maternal/Child.

Vitamin K deficiency:

1 to 2 mg/dose times 1 dose.

Reversal of vitamin K antagonists (e.g., warfarin):

Limited data available. One source suggests 0.03 mg/kg/dose IV for excessively prolonged INR (usually INR >8, no evidence of bleeding) due to vitamin K antagonist.

NEWBORN DOSE

See Usual Dose, Precautions, and Maternal/Child. Rarely given IV in the newborn.

Prophylaxis of vitamin K–deficiency bleeding in neonates:

0.5 to 1 mg IM within 1 hour of birth.

Treatment of vitamin K–deficiency bleeding in neonates:

1 mg SC or IM. Higher doses may be necessary if the mother has been receiving oral anticoagulants (e.g., warfarin [Coumadin]) or anticonvulsants (e.g., phenytoin [Dilantin]).

DOSE ADJUSTMENTS

See Drug/Lab Interactions.

DILUTION

Dilute with NS, D5NS, or D5W. Avoid use of other diluents that may contain benzyl alcohol. Dilution with at least 50 mL of diluent is recommended to facilitate prescribed rate of administration. Photosensitive; protect from light in all dilutions. Use immediately after preparation.

Filters:

Not required by manufacturer; however, there should be no significant loss of potency with the use of a 0.22-micron filter.

Storage:

Photosensitive; protect from light before use and in all dilutions. Store unopened ampules below 40° C (104° F), preferably between 15° and 30° C (59° and 86° F) in original carton. Protect from light and freezing. Discard diluted solution and drug remaining in ampule after single use.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Generally diluted in 50 mL of **compatible** solution and given over 15 to 20 minutes;

not to exceed 1 mg/min. Too-rapid injection has caused severe reactions, including fatalities.

ACTIONS

Vitamin K, a fat-soluble vitamin, is essential for hepatic production of four blood coagulation factors (II [prothrombin], VII, IX, X). These are required for normal blood clotting. Onset of action is within 1 to 2 hours. Usually controls hemorrhage in 3 to 6 hours; normal INR should be obtained in 12 to 14 hours. Metabolized by the liver and eliminated in urine and feces. Crosses the placenta and is present in breast milk.

INDICATIONS AND USES

Treatment of the following coagulation disorders due to faulty formation of factors II, VII, IX, and X when caused by vitamin K deficiency or interference with vitamin K activity:

- Anticoagulant-induced hypoprothrombinemia caused by warfarin or indanedione derivatives
- Hypoprothrombinemia due to antibacterial therapy
- Hypoprothrombinemia secondary to factors limiting the absorption or synthesis of vitamin K (e.g., obstructive jaundice, biliary fistula, sprue, ulcerative colitis, celiac disease, intestinal resection, cystic fibrosis of the pancreas, and regional enteritis)
- Other drug-induced hypoprothrombinemia in which it is definitively shown that the result is due to interference with vitamin K metabolism (e.g., salicylates).
- Prophylaxis and treatment of vitamin K–deficiency bleeding in neonates.

CONTRAINDICATIONS

Hypersensitivity to phytonadione or any components of this medication.

PRECAUTIONS

Fatal and severe hypersensitivity reactions, including anaphylaxis, have occurred during and immediately after IV and IM injection. Reactions have occurred despite dilution to avoid rapid IV infusion and upon first dose. IV and/or IM is not the route of choice; used only when SC or oral route cannot be used. ■ As an alternative to administering phytonadione, discontinuation or reduction of the doses of drugs interfering with coagulation mechanisms (e.g., antibiotics, salicylates) should be considered. The severity of the coagulation disorder should determine whether phytonadione is required in addition to discontinuing or reducing the doses of interfering drugs. To correct excess anticoagulation after the use of warfarin (e.g., returning an increased INR to the desired range), consider the degree of elevation of the INR and the presence of clinically significant bleeding. ■ Coagulant effects of phytonadione are not immediate; improvement of INR may take 1 to 8 hours. Consider supplementation with whole blood transfusion or blood components if bleeding is severe. ■ When phytonadione is used to correct excessive anticoagulant-induced hypoprothrombinemia in a patient for whom anticoagulant therapy is indicated, the same clotting hazards that existed before beginning anticoagulant therapy will recur. Use the smallest dose of phytonadione possible and monitor INR. ■ Cutaneous reactions, including eczematous reactions, scleroderma-like patches, urticaria, and delayed-type hypersensitivity reactions, have occurred with parenteral administration of phytonadione. Time of onset ranged from 1 day to 1 year after parenteral administration. Discontinue phytonadione for skin reactions and institute medical management.

Monitor:

See Neonatal Dose, Precautions, and Drug/Lab Interactions. ■ Monitor PT/INR regularly and as clinical conditions indicate. Coagulant effects of phytonadione are not immediate; improvement of INR may take 1 to 8 hours. Repeat PT/INR 6 to 8 hours after a dose. Subsequent dose(s) will be based on INR and clinical condition. ■ Monitor for S/S of a hypersensitivity reaction (e.g., cardiorespiratory arrest, chest pain, cyanosis, diaphoresis, dyspnea, flushing, shock, tachycardia, and weakness). ■ Monitor for cutaneous reactions.

Patient Education:

Read the FDA-approved patient labeling. ■ Promptly report signs of hypersensitivity. ■ Gasping syndrome has occurred after administration of products containing benzyl alcohol to neonates and infants and pregnant women. ■ Report the occurrence of new rashes. Cutaneous reactions may be delayed for up to 1 year after administration of phytonadione.

Maternal/Child:

Safety for use during pregnancy not established. ■ Pregnant women with vitamin K–deficiency hypoprothrombinemia may be at increased risk for bleeding diatheses during pregnancy and for hemorrhagic events at delivery. Subclinical maternal vitamin K deficiency during pregnancy has been implicated in rare cases of fetal intracranial hemorrhage. ■ Use caution during breast-feeding. ■ Safety and effectiveness for prophylaxis and treatment of vitamin K deficiency have been established in neonates. ■ Use extreme caution in premature infants and neonates. Hemolysis, jaundice, and hyperbilirubinemia in newborns may result from an overdose of phytonadione. ■ Neonates with vitamin K–deficiency bleeding should respond to administration of phytonadione with a shortening of the INR within 2 to 4 hours. If shortening of the INR is not seen, consider another diagnosis or coagulation disorder. ■ May contain benzyl alcohol. Serious and fatal adverse reactions including “gasping syndrome” (characterized by CNS depression, gasping respirations, and metabolic acidosis) can occur in neonates and infants treated with benzyl alcohol–preserved medications, including phytonadione. Whenever possible, administer benzyl alcohol–free formulations in pediatric patients, pregnant women, and breast-feeding women. When used as recommended, there is no evidence to suggest that this small amount is associated with toxicity.

DRUG/LAB INTERACTIONS

Discontinue drugs **adversely affecting the coagulation mechanism** if possible (e.g., salicylates, antibiotics). ■ May cause temporary resistance to **prothrombin-**

depressing oral anticoagulants. When resuming anticoagulant therapy, a higher dose of anticoagulant or a change in therapy to a different class of anticoagulant (e.g., heparin) may be necessary. ■ Phytonadione does not affect the anticoagulant action of heparin.

SIDE EFFECTS

The most common adverse reactions include cyanosis, diaphoresis, dizziness, dysgeusia, dyspnea, flushing, hypotension, and tachycardia. Other reported reactions include erythema, erythema perstans, hyperbilirubinemia, injection site reactions, pruritic plaques, and scleroderma-like lesions. Hypersensitivity reactions (including anaphylaxis), cardiac and/or respiratory arrest, shock, and death have occurred with parenteral route.

ANTIDOTE

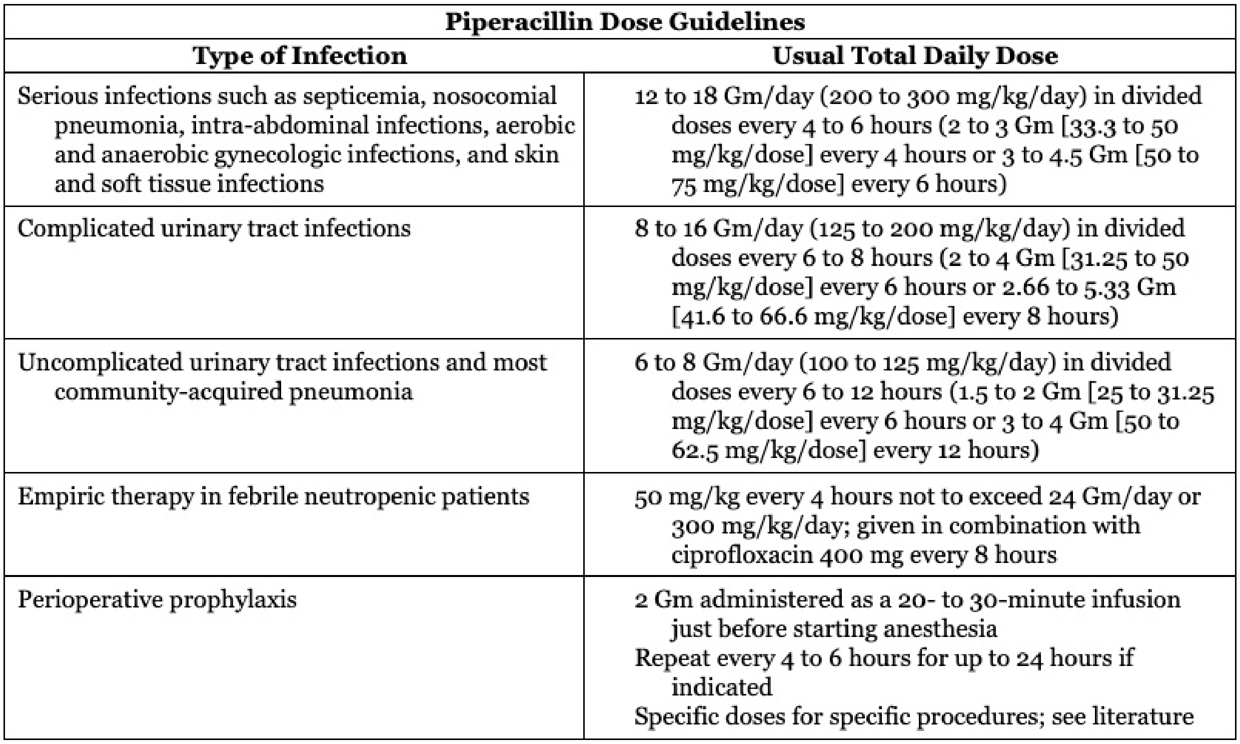
Should not be necessary if dosage is accurately calculated before administration. Notify the physician of any side effects. Discontinue administration in the event of a severe hypersensitivity reaction. Treat hypersensitivity reactions as necessary.

PIPERACILLIN SODIUM

(pie-**PER**-ah-sill-in **SO**-dee-um)
Antibacterial (extended-spectrum penicillin)
pH 5.5 to 7.5

USUAL DOSE

3 to 4 Gm every 4 to 6 hours depending on severity of infection. Maximum dose usually 24 Gm/24 hr. Usual duration of therapy is 7 to 10 days (3 to 10 days for treatment of gynecologic infections). Dosage recommendations for different types of infections are listed in the following chart.



Piperacillin Dose Guidelines	
Type of Infection	**Usual Total Daily Dose**
Serious infections such as septicemia, nosocomial pneumonia, intra-abdominal infections, aerobic and anaerobic gynecologic infections, and skin and soft tissue infections	12 to 18 Gm/day (200 to 300 mg/kg/day) in divided doses every 4 to 6 hours (2 to 3 Gm [33.3 to 50 mg/kg/dose] every 4 hours or 3 to 4.5 Gm [50 to 75 mg/kg/dose] every 6 hours)
Complicated urinary tract infections	8 to 16 Gm/day (125 to 200 mg/kg/day) in divided doses every 6 to 8 hours (2 to 4 Gm [31.25 to 50 mg/kg/dose] every 6 hours or 2.66 to 5.33 Gm [41.6 to 66.6 mg/kg/dose] every 8 hours)
Uncomplicated urinary tract infections and most community-acquired pneumonia	6 to 8 Gm/day (100 to 125 mg/kg/day) in divided doses every 6 to 12 hours (1.5 to 2 Gm [25 to 31.25 mg/kg/dose] every 6 hours or 3 to 4 Gm [50 to 62.5 mg/kg/dose] every 12 hours)
Empiric therapy in febrile neutropenic patients	50 mg/kg every 4 hours not to exceed 24 Gm/day or 300 mg/kg/day; given in combination with ciprofloxacin 400 mg every 8 hours
Perioperative prophylaxis	2 Gm administered as a 20- to 30-minute infusion just before starting anesthesia Repeat every 4 to 6 hours for up to 24 hours if indicated Specific doses for specific procedures; see literature

PEDIATRIC DOSE

Safety and effectiveness not established for pediatric patients under 12 years of age. All IV doses are unlabeled; see Maternal/Child. Do not exceed adult dose.

200 to 300 mg/kg/24 hr in equally divided doses every 4 to 6 hours (33.3 to 50 mg/kg every 4 hours or 50 to 75 mg/kg every 6 hours).

Cystic fibrosis in pediatric patients under 12 years of age:

350 to 600 mg/kg/24 hr in equally divided doses every 4 to 6 hours (58.33 to 100 mg/kg every 4 hours or 87.5 to 150 mg/kg every 6 hours).

NEONATAL DOSE

See comments under Pediatric Dose.

Premature infants (less than 36 weeks' gestation) under 7 days of age:

75 mg/kg every 12 hours. **7 days of age or older:** 75 mg/kg every 8 hours.

Full-term infants under 7 days of age:

75 mg/kg every 8 hours. **7 days of age or older:** 75 mg/kg every 6 hours.

Another source suggests the following doses for bacterial meningitis:

7 days of age or younger and 2 kg or less:

50 mg every 12 hours; **over 2 kg:** 50 mg every 8 hours.

Over 7 days of age and 2 kg or less:

50 mg every 8 hours; **over 2 kg:** 50 mg every 6 hours.

DOSE ADJUSTMENTS

Reduced dose may be required in the elderly; see Elderly. ■ Reduce dose in patients with impaired renal function according to the following chart.

Piperacillin Dose Guidelines in Impaired Renal Function[a]

Creatinine Clearance (mL/min)	Urinary Tract Infection (uncomplicated)	Urinary Tract Infection (complicated)	Serious Systemic Infection
>40 mL/min	No dose adjustment necessary		
20 to 40 mL/min	No dose adjustment necessary	9 Gm/day total; give 3 Gm q 8 hr	12 Gm/day total; give 4 Gm q 8 hr
<20 mL/min	6 Gm/day total; give 3 Gm q 12 hr	6 Gm/day total; give 3 Gm q 12 hr	8 Gm/day total; give 4 Gm q 12 hr
Hemodialysis[b]	6 Gm/day total; give 2 Gm q 8 hr	6 Gm/day total; give 2 Gm q 8 hr	6 Gm/day total; give 2 Gm q 8 hr

[a] Measure serum levels of piperacillin to guide dose adjustment in patients with renal failure and hepatic insufficiency.

[b] Hemodialysis removes 30% to 50% of piperacillin. Administer an additional 1-Gm dose following each dialysis session.

DILUTION

Each 1 Gm or fraction thereof should be reconstituted with at least 5 mL of SWFI, NS, D5W, or D5NS. Shake vigorously to dissolve. May be further diluted to desired volume (50 to 100 mL) with D5W, NS, D5NS, LR, or Dextran 6%/NS, and given as an intermittent infusion.

Storage:

Store unopened vials at CRT. Stable at room temperature for 24 hours. Reconstituted vials are stable for 24 hours at RT and 48 hours if refrigerated. Diluted solutions stable for 24 hours at RT, up to 1 week refrigerated, and up to 1 month frozen. Use solutions diluted with LR within 2 hours. Do not refrigerate or freeze ADD-Vantage formulations.

COMPATIBILITY

Inactivated in solution with aminoglycosides (e.g., amikacin [Amikin], gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. See Drug/Lab Interactions. Manufacturer states, "**Compatible** with KCl 40 mEq in D5W, NS, D5NS, LR, or Dextran 6%/NS."

RATE OF ADMINISTRATION

Too-rapid injection may cause seizures.

IV injection:

A single dose over 3 to 5 minutes.

Intermittent infusion:

A single dose properly diluted over 20 to 30 minutes. Discontinue primary IV infusion during administration. Slow infusion rate for pain along venipuncture site.

ACTIONS

An extended-spectrum penicillin. Bactericidal against a variety of gram-negative and gram-positive bacteria, including aerobic and anaerobic strains. Especially effective against *Klebsiella* and *Pseudomonas*. Mode of action involves inhibition of both septum and cell wall synthesis. Widely distributed in tissues and body fluids, including bone, prostate, and heart. Reaches high concentrations in bile and penetrates into CSF through inflamed meninges. Onset of action is prompt. Eliminated primarily by glomerular filtration and tubular secretion. Excreted rapidly as unchanged drug in the urine and to a lesser extent in bile. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, intra-abdominal, urinary tract, gynecologic, hepatobiliary, skin and skin structure, bone and joint, and gonococcal infections and septicemia caused by susceptible organisms. May be used in either liver or renal impairment since excretion occurs in bile and urine. Frequently used to initiate therapy in serious infections because of broad spectrum. ■ Perioperative prophylaxis.

CONTRAINDICATIONS

History of a hypersensitivity reaction to any penicillin or cephalosporin (not absolute; see Precautions).

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients on penicillin therapy; most likely to occur in patients with a history of penicillin hypersensitivity or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to piperacillin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, piperacillin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Incidence of side effects (e.g., fever and rash) increased in patients with cystic fibrosis. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with piperacillin. ■ Bleeding manifestations have been reported and may be associated with abnormal coagulation tests (e.g., clotting time, platelet aggregation, and PT). ■ Patients with impaired renal function may be at increased risk for bleeding tendencies. ■ Administration of higher than recommended doses has resulted in neuromuscular excitability and convulsions. ■ Leukopenia and neutropenia have been reported. Usually reversible and is more likely to occur in patients receiving prolonged therapy at high doses or in association with drugs known to cause this reaction.

Monitor:

Watch for early symptoms of a hypersensitivity reaction. ■ Periodic evaluation of renal, hepatic, and hematopoietic systems and serum potassium is recommended in prolonged therapy. Observe for hypokalemia and increased bleeding tendencies. ■ All patients with gonorrhea (IM indication) should be tested for syphilis at the time of diagnosis and have a follow-up test 3 months after treatment with piperacillin. ■ Observe for electrolyte imbalance and cardiac irregularities. Contains 1.85 mEq sodium/Gm. May aggravate CHF. ■ May cause thrombophlebitis; observe carefully and rotate infusion sites. ■ See Drug/Lab Interactions.

Patient Education:

May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category B: use only if absolutely necessary in pregnancy and breast-feeding. ■ May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Safety for use in pediatric patients under 12 years not established but is used. ■ Half-life in neonates is two- to four-fold longer than that seen in infants 1 month of age and above or in adults. Half-life is shorter in infants and other pediatric patients compared to adults.

Elderly:

No problems documented. Caution and lower-end dosing suggested based on potential for decreased organ function and concomitant disease or drug therapy. Age-related decrease in renal function may require decreased dose.

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **aminoglycosides**. Synergism may be inconsistent; see Compatibility. ■ Concomitant use with **beta-adrenergic blockers** may increase risk of anaphylaxis and inhibit treatment. ■ Risk of bleeding may be increased with **anticoagulants**; monitoring of coagulation tests may be indicated. Use caution. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ May inhibit effectiveness of **oral contraceptives;** could result in breakthrough bleeding or pregnancy. ■ **Probenecid** decreases rate of piperacillin elimination resulting in higher and more prolonged blood levels. May be desirable or may cause toxicity. ■ May prolong neuromuscular blockade with **vecuronium.** ■ May decrease clearance and increase toxicity of **methotrexate.** If concurrent use is necessary, monitor for S/S of methotrexate toxicity and monitor methotrexate levels. ■ May cause **false urine protein reactions** with various tests; see Side Effects and/or literature.

SIDE EFFECTS

Agranulocytosis; anaphylaxis; CDAD; convulsions; diarrhea; dizziness; elevated SCr, BUN, alkaline phosphatase, LDH, serum bilirubin, AST, and ALT; erythema multiforme; fatigue; fever; headache; hemolytic anemia; hypokalemia; increased creatinine or BUN; injection site reactions; interstitial nephritis; leukopenia; muscle relaxation (prolonged); nausea; neutropenia; prolonged bleeding time; pruritus; renal failure; skin rash; Stevens-Johnson syndrome; thrombocytopenia; thrombophlebitis; toxic epidermal necrolysis; urticaria; vomiting. Hypersensitivity myocarditis can occur (cardiomegaly, fever, eosinophilia, rash, sinus tachycardia, and ST-T changes). Higher than normal doses may cause neurologic adverse reactions, including convulsions, especially with impaired renal function.

ANTIDOTE

Notify the physician immediately of any adverse symptoms. For severe symptoms, discontinue the drug, treat hypersensitivity reactions (antihistamines, epinephrine, corticosteroids, airway management, and oxygen), and resuscitate as necessary. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Mild cases may respond to drug discontinuation alone. Hemodialysis is effective in overdose.

PIPERACILLIN SODIUM AND TAZOBACTAM SODIUM

(pie-**PER**-ah-sill-in **SO**-dee-um and tay-zoh-**BAC**-tam **SO**-dee-um)
Zosyn
Antibacterial (extended-spectrum penicillin and beta-lactamase inhibitor)
pH 5.5 to 6.8

USUAL DOSE

Measurement of both drugs is included in the total dose; for every 1 Gm of piperacillin there is 0.125 Gm of tazobactam (8:1 ratio).

12 Gm piperacillin/1.5 Gm tazobactam/24 hours given as 3.375 (3 Gm piperacillin/0.375 Gm tazobactam) every 6 hours. Usual duration of therapy is 7 to 10 days, based on severity of infection and patient progress.

Nosocomial pneumonia:

4.5 Gm every 6 hours. Also use an aminoglycoside. Continue aminoglycoside if *Pseudomonas aeruginosa* is isolated; may be discontinued if it is not isolated. Usual duration of therapy is 7 to 14 days.

PEDIATRIC DOSE

2 months to 9 months of age:

80 mg piperacillin/10 mg tazobactam per kg of body weight every 8 hours.

Over 9 months of age weighing up to 40 kg:

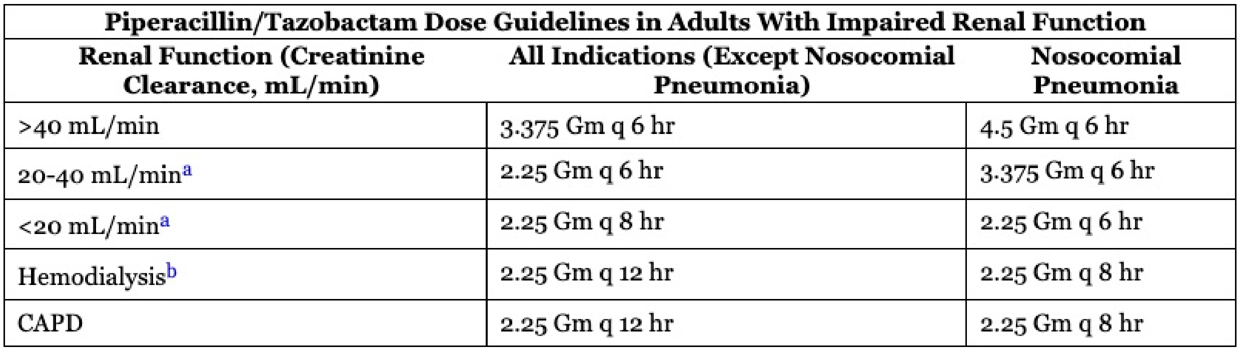
100 mg piperacillin/12.5 mg tazobactam per kg of body weight every 8 hours.

Pediatric patients over 40 kg:

See Usual Dose.

DOSE ADJUSTMENTS

No dose adjustment needed in impaired liver function. ■ Dose reduction may be required in the elderly. ■ Adjust dose in adult patients with impaired renal function based on the following chart. ■ Dose recommendations for pediatric patients with impaired renal function are not available.



Piperacillin/Tazobactam Dose Guidelines in Adults With Impaired Renal Function

Renal Function (Creatinine Clearance, mL/min)	All Indications (Except Nosocomial Pneumonia)	Nosocomial Pneumonia
>40 mL/min	3.375 Gm q 6 hr	4.5 Gm q 6 hr
20-40 mL/min[a]	2.25 Gm q 6 hr	3.375 Gm q 6 hr
<20 mL/min[a]	2.25 Gm q 8 hr	2.25 Gm q 6 hr
Hemodialysis[b]	2.25 Gm q 12 hr	2.25 Gm q 8 hr
CAPD	2.25 Gm q 12 hr	2.25 Gm q 8 hr

[a] Creatinine clearance for patients not receiving hemodialysis.

[b] Hemodialysis removes 30% to 40% of piperacillin/tazobactam. Give an additional dose of 0.75 Gm following each dialysis session. No additional dose is necessary for CAPD patients.

DILUTION

Available in two different formulations: one with EDTA (edetate disodium dihydrate) and one without. **Compatibility** information differs; consult pharmacist. See Compatibility.

Reconstitute 2.25 Gm, 3.375 Gm, and 4.5 Gm with 10 mL, 15 mL, and 20 mL, respectively, with SWFI or NS (with or without preservatives) or D5W. Swirl until dissolved. Should be further diluted to desired volume (50 to 150 mL) with **compatible** infusion solutions (NS, SWFI, Dextran 6% in Saline, or D5W). ***EDTA-containing formulation of Zosyn is compatible with all of the previously listed solutions plus LR.*** If further diluted with SWFI, maximum recommended volume of SWFI per dose is 50 mL. May be reconstituted and instilled into an ambulatory IV infusion pump. Considered stable at RT for 12 hours when reconstituted and diluted to a final volume of 25 or 37.5 mL. See manufacturer's literature for additional information. Also available premixed in ADD-Vantage vials for use with ADD-Vantage infusion containers and as a frozen premixed solution.

Storage:

Store unopened vials at RT. Use single-dose vials immediately after reconstitution; discard any unused portion after 24 hours at room temperature or 48 hours if refrigerated. Do not freeze vials after reconstitution. Stable for 24 hours at RT or for up to 7 days after dilution if refrigerated. Store frozen solution at −20° C (−4° F). Frozen solutions should be thawed at RT or under refrigeration. Do not force thaw. Thawed solutions are stable for 24 hours at RT or for 14 days if refrigerated. Do not refreeze.

COMPATIBILITY

Manufacturer states, "Should not be mixed with other drugs in a syringe or infusion bottle. Not chemically stable in solutions containing only sodium bicarbonate and/or solutions that significantly alter the pH. **Incompatible** with LR ***(the EDTA-free formulation of Zosyn only)*** and should not be added to blood products or albumin hydrolysates." Manufacturer recommends temporarily discontinuing other solutions infusing at the same site to avoid compatibility problems. Piperacillin may inactivate aminoglycosides (e.g., amikacin, gentamicin). Do not mix in the same solution. Separate administration required. Formulation containing EDTA **may be compatible** at the **Y-site** with amikacin or gentamicin. Selected doses, specific diluents, and amounts of diluent are required. Consult pharmacist or manufacturer's literature. See Drug/Lab Interactions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose over 30 minutes as an intermittent infusion. Discontinue primary IV infusion during administration. Retrospective data have shown that giving IV push over 2 to 5 minutes has been generally safe and tolerable when reconstituted with SWI 20 mL. Monitor for phlebitis and other infusion-related reactions.

Extended infusion method (unlabeled dosing):

3.375 to 4.5 Gm IV over 4 hours every 8 hours.

ACTIONS

An antimicrobial agent that combines the extended-spectrum penicillin piperacillin with the potent beta-lactamase inhibitor tazobactam. May be used in suspected polymicrobial infections due to its broad spectrum of activity. Acts by inhibiting septum formation and cell wall synthesis of susceptible bacteria. Bactericidal against gram-positive aerobes, gram-negative aerobes, and anaerobes that may be resistant to other antibiotics. Widely distributed into most body fluids and tissues. Mean tissue concentrations are 50% to 100% of plasma concentrations. Peak levels are achieved immediately at the completion of an infusion. Plasma half-life ranges from 0.7 to 1.2 hours. Metabolized and excreted in urine and, to a small extent, in bile. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of patients with moderate to severe infections caused by piperacillin/tazobactam–susceptible strains of specific microorganisms in the following conditions: intra-abdominal (e.g., appendicitis complicated by rupture or abscess and peritonitis), gynecologic (e.g., postpartum endometritis and pelvic inflammatory disease), skin and skin structure (complicated and uncomplicated [e.g., cellulitis, cutaneous abscesses, and ischemic/diabetic foot infection]), community-acquired pneumonia (moderate severity only), and nosocomial pneumonia (moderate to severe severity). ■ Used in combination with aminoglycosides for nosocomial pneumonia caused by *Pseudomonas aeruginosa*.

Unlabeled uses:

Treatment of septicemia.

CONTRAINDICATIONS

History of hypersensitivity reaction to any penicillin, cephalosporin, or beta-lactamase inhibitors (not absolute; see Precautions).

PRECAUTIONS

Serious and occasionally fatal hypersensitivity reactions have been reported in patients receiving piperacillin sodium and tazobactam; most likely to occur in patients with a history of penicillin, cephalosporin, or carbapenem hypersensitivity or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Serious skin reactions such as Stevens-Johnson syndrome, toxic epidermal necrolysis, drug reaction with eosinophilia and systemic symptoms (DRESS), and generalized exanthematous pustulosis have been reported. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, piperacillin/tazobactam should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to piperacillin. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Bleeding manifestations have been reported and may be associated with abnormal coagulation tests (e.g., clotting time, platelet aggregation, and PT). Patients with impaired renal function may be at increased risk for bleeding tendencies. If bleeding occurs, discontinue therapy and institute appropriate measures ■ Leukopenia/neutropenia has been reported. Reaction appears to be reversible and is most common with prolonged therapy. ■ Use caution in patients with CHF or those with a history of bleeding disorders or GI disease (e.g., colitis). ■ *Clostridium difficile*–

associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with piperacillin/tazobactam. ■ Incidence of side effects (e.g., fever and rash) may be increased in patients with cystic fibrosis. ■ Administration of higher than recommended doses has resulted in neuromuscular excitability and convulsions. Patients with renal impairment are at increased risk. ■ In critically ill patients, the use of piperacillin sodium and tazobactam was found to be an independent risk factor for renal failure and was associated with delayed recovery of renal function compared with other beta-lactam antibacterial drugs. Consider alternative treatment options in critically ill patients. ■ See Drug/Lab Interactions.

Monitor:

Watch for early symptoms of a hypersensitivity reaction. ■ Closely monitor patients who develop a skin rash. Discontinue therapy if lesions progress. ■ Periodic evaluation of renal, hepatic, and hematopoietic systems and electrolytes recommended, especially with prolonged therapy. May cause hypokalemia; monitor closely. ■ Contains 2.84 mEq (65 mg) of sodium/Gm. At the usual recommended doses, patients would receive 34.1 to 45.5 mEq (780 to 1,040 mg) per day. Observe for electrolyte imbalance and cardiac irregularities. May aggravate CHF, especially in the elderly. ■ May cause thrombophlebitis; observe carefully and rotate infusion sites. ■ Observe for increased bleeding tendencies in all patients, especially those with impaired renal function. ■ See Drug/Lab Interactions.

Patient Education:

Report promptly: fever, rash, sore throat, unusual bleeding or bruising, or seizures. ■ May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Use during pregnancy only if clearly needed; data are insufficient. ■ Use caution in breast-feeding. No information is available on the effects of use on the breast-fed infant or on milk production. ■ Safety and effectiveness for use in pediatric patients under 2 months of age not established.

Elderly:

No problems documented. Consider age-related organ function and concomitant disease or drug therapy. Elderly patients may respond with a blunted natriuresis to salt loading, which can be clinically important with regard to diseases such as CHF.

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **aminoglycosides**. Synergism may be inconsistent; see Compatibility. ■ Piperacillin may inactivate **aminoglycosides** by converting them to microbiologically inert amides. Coadministration with aminoglycosides in patients with end-stage renal disease requiring hemodialysis may result in significant reduction of aminoglycoside concentrations. Monitor closely. ■

Concomitant administration with **vancomycin** may increase the incidence of acute kidney injury. Monitor renal function if concomitant use is required. No pharmacokinetic interactions have been noted between piperacillin/tazobactam and vancomycin. ■ Concomitant administration with **probenecid** decreases rate of elimination of piperacillin/tazobactam, resulting in higher and more prolonged blood levels. Avoid coadministration unless benefit outweighs risk. ■ Use caution with **anticoagulants** (e.g., heparin, warfarin) or **medications that affect platelet aggregation** (e.g., NSAIDs). Risk of bleeding may be increased. Monitoring of coagulation tests may be indicated. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, and tetracyclines); may interfere with bactericidal action. ■ May decrease clearance and increase toxicity of **methotrexate;** monitor methotrexate levels. ■ May prolong neuromuscular blockade with **vecuronium** or other nondepolarizing muscle relaxants. ■ May cause **false-positive glucose** with Clinitest. ■ **False-positive test results** using the Bio-Rad Laboratories Platelia Aspergillus EIA test in patients receiving piperacillin/tazobactam have been reported. ■ See Side Effects.

SIDE EFFECTS

The most common side effects include constipation, diarrhea, headache, insomnia, and nausea. Abdominal pain; abnormal coagulation tests (e.g., increased bleeding time, prolonged PT and PTT); abnormal LFTs; arthralgia; candidiasis; CDAD; dyspepsia; electrolyte abnormalities, including hypokalemia; epistaxis; fever; flushing; hematologic abnormalities (anemia, thrombocythemia, thrombocytopenia); hypoglycemia; hypotension; increased AST, BUN, and serum creatinine; local reactions; myalgia; phlebitis; positive Coombs' test; pruritus; pseudomembranous colitis; rash (e.g., bullous, maculopapular, urticarial); renal failure; rhinitis; rigors; seizures; sinusitis; thrombophlebitis; and vomiting have been reported. Anaphylaxis can occur. Transient leukopenia, neutropenia, and eosinophilia can occur with prolonged therapy.

Post-Marketing:

Agranulocytosis, dermatologic reactions (including acute generalized exanthematous pustulosis, exfoliative dermatitis, erythema multiforme, DRESS, Stevens-Johnson syndrome, and toxic epidermal necrolysis), eosinophilic pneumonia, hemolytic anemia, hepatitis, hypersensitivity reactions (including anaphylactic/anaphylactoid reactions), interstitial nephritis, jaundice, and pancytopenia.

ANTIDOTE

Notify physician immediately of any adverse symptoms. For severe symptoms, discontinue drug, treat hypersensitivity reactions (antihistamines, epinephrine, corticosteroids, airway management, oxygen), and resuscitate as necessary. Use anticonvulsants for seizures. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Mild cases may respond to drug discontinuation alone. Hemodialysis is effective in overdose.

PLASMA PROTEIN FRACTION

(**PLAZ**-ma **PRO**-teen **FRAK**-shun)
Plasmanate, Plasmatein, Protenate
Plasma volume expander
pH 6.7 to 7.3

USUAL DOSE

Variable, depending on indication for use, condition of patient, and response to therapy. Range is from 250 to 1,500 mL/24 hr. Each 500-mL bottle yields 25 Gm of plasma protein. Suggested initial doses are as follows:

Shock:

250 to 500 mL.

Burns:

500 to 1,000 mL.

Hypoproteinemia:

1,000 to 1,500 mL/24 hr.

PEDIATRIC DOSE

Treatment of acute shock (unlabeled):

See Maternal/Child. One source recommends 10 to 30 mL/kg of body weight.

DILUTION

Available as a 5% solution buffered with saline in 250- and 500-mL bottles with injection sets. Plasmanate also available in a 50-mL size. No further dilution is required. Do not use if solution is turbid or a sediment is visible. Use immediately after opening and discard any unused portion. Contains no preservatives.

Storage:

Store at CRT.

COMPATIBILITY

Manufacturer lists as **incompatible** with solutions containing alcohol, protein hydrolysates, or amino acid products. Manufacturer states, "**Compatible** with the usual carbohydrate and electrolyte solutions."

RATE OF ADMINISTRATION

Variable, depending on indication, present blood volume, and patient response. Adjust or slow rate according to clinical response and rising BP. Averages are:

Normal blood volume:

1 mL/min.

Treatment of shock and burns in adult:

5 to 8 mL/min. Higher rates may be tolerated if necessary. Rapid infusion (over 10 mL/min) may cause hypotension. Decrease flow rate as patient improves.

Treatment of shock in infants and other pediatric patients:

5 to 10 mL/min. Do not exceed 10 mL/min in pediatric patients.

Treatment of hypoproteinemia:

Single 500-mL dose over 1 hour. For larger amounts the maximum rate is 100 mL/hr.

ACTIONS

A sterile, natural, plasma protein substance containing at least 83% albumin, no more than 17% alpha and beta globulins, and no more than 1% gamma globulin. Contains 130 to 160 mEq sodium/liter. It expands intravascular volume, prevents marked hemoconcentration, and maintains appropriate electrolyte balance in burns.

INDICATIONS AND USES

Emergency treatment of hypovolemic shock caused by burns, infections, surgery, or trauma (may also be due to dehydration in infants and other pediatric patients). ■ Temporary treatment of hemorrhage when whole blood unavailable. ■ Hypoproteinemia until cause determined and corrected. ■ Prevention of hemoconcentration and maintenance of electrolyte balance in burn patients.

CONTRAINDICATIONS

Cardiac failure, cardiopulmonary bypass, history of hypersensitivity reactions to albumin, normal or increased intravascular volume, severe anemia.

PRECAUTIONS

May be given without regard to blood group or type. ■ Not effective for coagulation mechanism defects. ■ Added protein, fluid, and sodium load requires caution in hepatic or renal impairment. ■ If continuous protein loss occurs or edema is present, normal serum albumin (25%) may be the preferred product.

Monitor:

Monitor vital signs (including central venous pressure if possible) and urine output every 5 to 15 minutes for 1 hour and hourly thereafter depending on condition. ■ For treatment of shock, observe carefully for bleeding points that may not have been evident at lower pressures. ■ Whole blood may be indicated for considerable RBC loss or anemia caused by administration of large amounts of plasma protein fraction. ■ Additional fluids are required for dehydrated patients. Tissue dehydration caused by osmotic action of plasma proteins can be acute. ■ May cause vascular overload; monitor for signs of pulmonary edema or heart failure (e.g., dyspnea, fluid in the lungs, abnormal increases in BP or CVP). ■ Hemoglobin, hematocrit, electrolyte, and serum protein evaluations are necessary during therapy.

Maternal/Child:

Category C: safety for use in pregnancy not established. ■ Safety and effectiveness for use in pediatric patients not established.

DRUG/LAB INTERACTIONS

May cause an **elevated alkaline phosphatase** level.

SIDE EFFECTS

Hypersensitivity and/or pyrogenic reactions can occur. Incidence of toxicity is low when administered with appropriate caution. Slight nausea can occur. Hypotension can be sudden if administered too rapidly.

ANTIDOTE

Notify the physician of all symptoms and side effects. Discontinue infusion for sudden hypotension. Decrease flow rate if indicated and treat symptomatically. Resuscitate as necessary.

PLAZOMICIN BBW

(pla-zoe-**MYE**-sin)
Zemdri
Antibacterial (aminoglycoside)
pH 6.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Precautions and Monitor. See Maternal/Child.

Plazomicin:

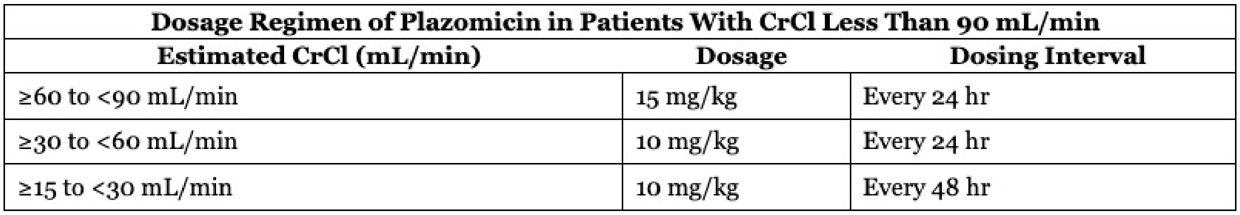
15 mg/kg as an IV infusion over 30 minutes every 24 hours in patients with a CrCl greater than or equal to 90 mL/min; see Dose Adjustments. Duration of therapy is 4 to 7 days and should be guided by the severity of the infection and the patient’s clinical status. Conversion to appropriate oral therapy may be considered after 4 to 7 days of plazomicin therapy to complete a total duration of 7 to 10 days (IV plus oral).

DOSE ADJUSTMENTS

CrCl is estimated by the Cockcroft-Gault formula using total body weight (TBW). For patients with a CrCl greater than or equal to 90 mL/min and a TBW greater than ideal body weight (IBW) by 25% or more, use IBW or use adjusted body weight based on the equation:

$$\text{Adjusted body weight} = \text{IBW} + 0.4 \times (\text{TBW} - \text{IBW})$$

■ The recommended **initial dose** for patients with CrCl greater than or equal to 15 and less than 90 mL/min as estimated by the Cockcroft-Gault formula is described in the following chart.



Dosage Regimen of Plazomicin in Patients With CrCl Less Than 90 mL/min		
Estimated CrCl (mL/min)	**Dosage**	**Dosing Interval**
≥60 to <90 mL/min	15 mg/kg	Every 24 hr
≥30 to <60 mL/min	10 mg/kg	Every 24 hr
≥15 to <30 mL/min	10 mg/kg	Every 48 hr

■ Patients with CrCl greater than or equal to 15 and less than 90 mL/min may require **subsequent dosage adjustments** based on change in renal function and/or therapeutic drug monitoring (TDM). ■ For patients with a plazomicin plasma trough concentration 3 mcg/mL or higher, extend the plazomicin dosing interval by 1.5-fold (i.e., from every 24 hours to every 36 hours or from every 48 hours to every 72 hours); see Monitor. ■ There is insufficient information to recommend a dosage regimen in patients with CrCl less than 15 mL/min or in patients on renal replacement therapy, including hemodialysis or continuous renal replacement therapy. ■ Dosing in elderly patients should be cautious and reduced based on CrCl; consider potential for decreased organ function and concomitant disease or drug therapy. ■ No clinically significant differences in the pharmacokinetics of plazomicin were observed based on age, sex, or race/ethnicity. The pharmacokinetics of plazomicin in patients with hepatic impairment is unknown.

DILUTION

Available in a single-dose vial containing plazomicin 500 mg/10 mL (50 mg/mL) as a clear, colorless to yellow solution. Withdraw the appropriate volume of plazomicin to provide the calculated dose and dilute in NS or LR to achieve a final volume of 50 mL.

Filter:

Specific information not available.

Storage:

Store unopened vials at 2° to 8° C (36° to 46° F). After dilution, plazomicin is stable for 24 hours at RT at concentrations of 2.5 to 45 mg/mL. Discard any unused portion in the vial.

COMPATIBILITY

Manufacturer states, “Plazomicin should not be mixed with other drugs or physically added to solutions containing other drugs. Other medications should not be infused simultaneously with plazomicin through the same IV line.”

RATE OF ADMINISTRATION

Each single dose, properly diluted, over 30 minutes.

ACTIONS

A semi-synthetic aminoglycoside antibacterial agent that acts by binding to the 30s ribosomal subunit, thereby inhibiting protein synthesis. Has concentration-dependent bactericidal activity against specific gram-negative bacilli; see prescribing information and Indications. In vitro studies demonstrated a plazomicin postantibiotic effect ranging from 0.2 to 2.6 hours at 2 × minimum inhibitory concentration (MIC) against Enterobacteriaceae. Protein binding is approximately 20%. Plazomicin does not appear to be metabolized. Half-life is 3 to 4 hours. Primarily excreted by the kidneys. Crosses the placental barrier.

INDICATIONS AND USES

Indicated in patients 18 years of age or older for the treatment of a complicated urinary tract infection (cUTI), including pyelonephritis caused by the following susceptible microorganism(s): *Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis,* and *Enterobacter cloacae.*

CONTRAINDICATIONS

Known hypersensitivity to any aminoglycoside.

PRECAUTIONS

Nephrotoxicity has been reported. Risk of nephrotoxicity is greater in patients with impaired renal function, elderly patients, and patients receiving concomitant nephrotoxic medications. Most serum creatinine increases were 1 mg/dL or less above baseline and reversible. In the setting of worsening renal function, consider risk versus benefit of continuing therapy. ■ Ototoxicity manifested as hearing loss, tinnitus, and/or vertigo has been reported. Symptoms of aminoglycoside-associated ototoxicity may be irreversible and may not become evident until after completion of therapy. Aminoglycoside-associated ototoxicity has been observed primarily in patients with a family history of hearing loss, patients with renal impairment, and patients receiving higher doses and/or longer durations of therapy than recommended. Consider risk versus benefit of administering plazomicin in patients with a history of hearing loss. ■ Aminoglycosides have been associated with neuromuscular blockade. May exacerbate muscle weakness in patients with underlying neuromuscular disorders or delay recovery of neuromuscular function in patients receiving concomitant neuromuscular blocking agents. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, plazomicin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to plazomicin. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ Serious and occasionally fatal hypersensitivity (anaphylactic) reactions have been reported in patients receiving aminoglycoside antibacterial drugs. Cross-sensitivity among aminoglycosides has been established. Obtain medication allergy history before initiating therapy; see Contraindications. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with plazomicin. ■ May be active against some organisms that are normally resistant to other aminoglycosides.

Monitor:

Assess creatinine clearance in all patients before initiating therapy and daily during therapy, particularly in those at increased risk for nephrotoxicity; see Precautions. ■ Monitor urinalysis, BUN, SCr, and urine output. ■ To avoid potentially toxic levels, therapeutic drug monitoring (TDM) is recommended for patients with a complicated urinary tract infection (cUTI) who have a CrCl less than 90 mL/min. Measure plazomicin plasma trough concentration approximately 30 minutes before administration of the second dose of plazomicin; see Dose Adjustments. ■ Monitor for adverse reactions associated with neuromuscular blockade (e.g., exacerbation of muscle weakness), particularly in high-risk patients, such as patients with underlying neuromuscular disorders (including myasthenia gravis), or in patients concomitantly receiving neuromuscular blocking agents. ■ Monitor for symptoms of ototoxicity. ■ Closely monitor patients with impaired renal function for nephrotoxicity and ototoxicity.

Patient Education:

Review health and medication history with health care provider. ■ Maintain hydration. ■ Laboratory testing required. ■ Promptly report dizziness, hearing loss, muscle weakness, any changes in balance, or S/S of a hypersensitivity reaction. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ May cause fetal harm. Report suspected pregnancy immediately and consider effective birth control options.

Maternal/Child:

Aminoglycosides, including plazomicin, can cause fetal harm when administered to a pregnant woman. Use of streptomycin, another aminoglycoside, has been associated with several reports of total, irreversible, bilateral congenital deafness in pediatric patients exposed in utero. ■ Safety for use during breast-feeding not established; use caution and consider risk versus benefit. ■ Safety and effectiveness in patients under 18 years of age have not been established.

Elderly:

Incidence of side effects was higher in patients over 65 years of age compared with younger patients. ■ Consider age-related changes in renal function. ■ Monitor renal function and plasma plazomicin levels as appropriate; see Dose Adjustments and Precautions.

DRUG/LAB INTERACTIONS

Specific information is not available for plazomicin. ■ In vitro studies have demonstrated that against Enterobacteriaceae isolates, no antagonism was observed for plazomicin in combination with clindamycin, colistin, daptomycin, fosfomycin, levofloxacin, linezolid, rifampin, tigecycline, and vancomycin; few isolates showed synergy with ceftazidime, meropenem, and piperacillin/tazobactam. The clinical significance of these findings is unknown. ■ Risk of nephrotoxicity increased with concomitant administration of other **nephrotoxic medications**. ■ May delay recovery in patients receiving concomitant **neuromuscular blockers**.

SIDE EFFECTS

The most common adverse reactions are decreased renal function, diarrhea, headache, hypertension, hypotension, nausea, and vomiting. CDAD, hypersensitivity reactions, neuromuscular blockade, and ototoxicity have also been reported with plazomicin and/or other aminoglycoside antibacterial agents; see Precautions. Other adverse reactions that were reported in a small number of patients receiving plazomicin include constipation, dizziness, dyspnea, gastritis, hematuria, hypokalemia, and increased ALT.

ANTIDOTE

Notify the physician of all side effects. For severe symptoms, discontinue the drug. Treat hypersensitivity reactions as indicated (e.g., antihistamines, epinephrine, corticosteroids) and resuscitate as necessary. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin), as indicated. In severe cases, surgical evaluation may be indicated. In the event of an overdose, discontinue plazomicin, provide supportive care, and monitor renal function closely. Hemodialysis may be effective in overdose, especially if renal function is or becomes compromised.

POLATUZUMAB VEDOTIN-piiq

(**POOL**-a-**TOOZ**-ue-mab ve-**DOE**-tin)
Polivy
Antineoplastic
Anti-CD79b-directed antineoplastic
Antibody-drug conjugate (ADC)
pH 5.3

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Premedication:

If not already premedicated for the rituximab product, administer an antihistamine (e.g., diphenhydramine) and an antipyretic (e.g., acetaminophen) at least 30 minutes before polatuzumab dose to prevent or attenuate infusion reactions.

Prophylaxis:

Administer **prophylaxis** for *Pneumocystis jiroveci* pneumonia and herpesvirus throughout treatment with polatuzumab.

Polatuzumab vedotin-piiq:

1.8 mg/kg as an IV infusion every 21 days for 6 cycles in combination with bendamustine and a rituximab product. Administer polatuzumab, bendamustine, and the rituximab product in any order on Day 1 of each cycle.

Bendamustine:

90 mg/M^2/day as an IV infusion on Day 1 and Day 2 of each cycle when given with polatuzumab and a rituximab product.

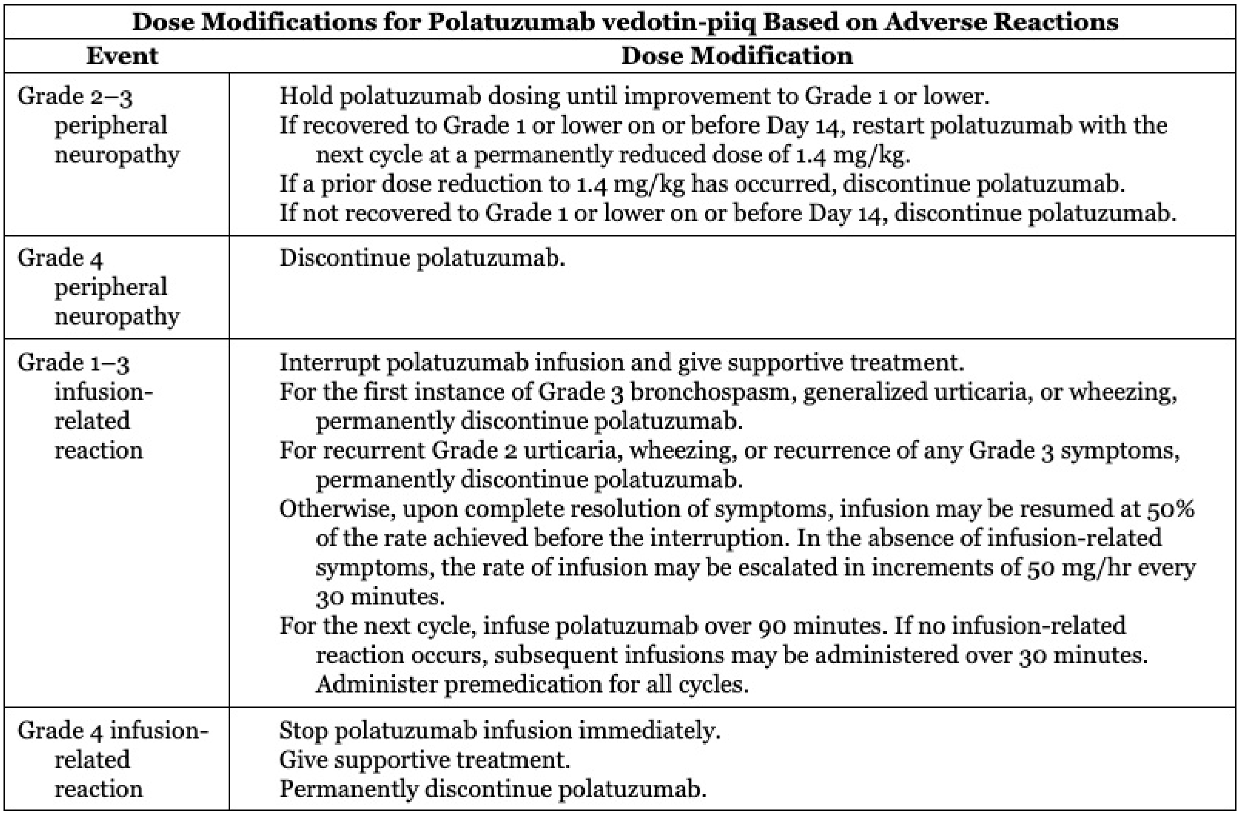
Rituximab product:

375 mg/M^2 as an IV infusion on Day 1 of each cycle when given with polatuzumab and bendamustine.

See prescribing information for chemotherapy drugs used in combination with polatuzumab vedotin-piiq.

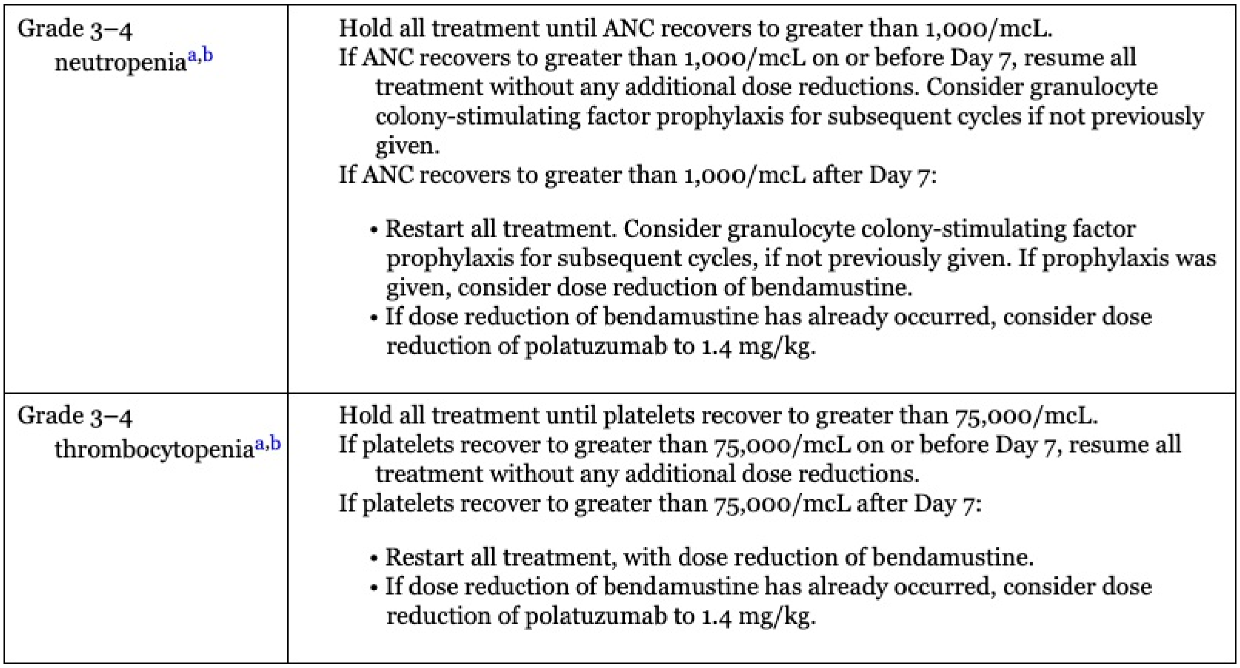
DOSE ADJUSTMENTS

If a planned dose of polatuzumab is missed, administer as soon as possible. Adjust the schedule of administration to maintain a 21-day interval between doses. ■ No starting dose adjustment is required in patients with mild hepatic impairment; see Precautions. ■ Dose modifications for adverse reactions are outlined in the following chart.



Dose Modifications for Polatuzumab vedotin-piiq Based on Adverse Reactions

Event	Dose Modification
Grade 2–3 peripheral neuropathy	Hold polatuzumab dosing until improvement to Grade 1 or lower. If recovered to Grade 1 or lower on or before Day 14, restart polatuzumab with the next cycle at a permanently reduced dose of 1.4 mg/kg. If a prior dose reduction to 1.4 mg/kg has occurred, discontinue polatuzumab. If not recovered to Grade 1 or lower on or before Day 14, discontinue polatuzumab.
Grade 4 peripheral neuropathy	Discontinue polatuzumab.
Grade 1–3 infusion-related reaction	Interrupt polatuzumab infusion and give supportive treatment. For the first instance of Grade 3 bronchospasm, generalized urticaria, or wheezing, permanently discontinue polatuzumab. For recurrent Grade 2 urticaria, wheezing, or recurrence of any Grade 3 symptoms, permanently discontinue polatuzumab. Otherwise, upon complete resolution of symptoms, infusion may be resumed at 50% of the rate achieved before the interruption. In the absence of infusion-related symptoms, the rate of infusion may be escalated in increments of 50 mg/hr every 30 minutes. For the next cycle, infuse polatuzumab over 90 minutes. If no infusion-related reaction occurs, subsequent infusions may be administered over 30 minutes. Administer premedication for all cycles.
Grade 4 infusion-related reaction	Stop polatuzumab infusion immediately. Give supportive treatment. Permanently discontinue polatuzumab.



Grade 3–4 neutropenia[a,b]	Hold all treatment until ANC recovers to greater than 1,000/mcL. If ANC recovers to greater than 1,000/mcL on or before Day 7, resume all treatment without any additional dose reductions. Consider granulocyte colony-stimulating factor prophylaxis for subsequent cycles if not previously given. If ANC recovers to greater than 1,000/mcL after Day 7: • Restart all treatment. Consider granulocyte colony-stimulating factor prophylaxis for subsequent cycles, if not previously given. If prophylaxis was given, consider dose reduction of bendamustine. • If dose reduction of bendamustine has already occurred, consider dose reduction of polatuzumab to 1.4 mg/kg.
Grade 3–4 thrombocytopenia[a,b]	Hold all treatment until platelets recover to greater than 75,000/mcL. If platelets recover to greater than 75,000/mcL on or before Day 7, resume all treatment without any additional dose reductions. If platelets recover to greater than 75,000/mcL after Day 7: • Restart all treatment, with dose reduction of bendamustine. • If dose reduction of bendamustine has already occurred, consider dose reduction of polatuzumab to 1.4 mg/kg.

[a] Severity on Day 1 of any cycle.

[b] If primary cause is due to lymphoma, dose delay or reduction may not be needed.

DILUTION

Specific techniques required; see Precautions. Available as a lyophilized powder in a single-dose vial containing 140 mg. Reconstitute immediately before dilution. Calculate the number of vials required. For example, in a 70-kg patient:

$$1.8 \text{ mg/kg} \times 70 \text{ kg} = 126 \text{ mg}$$

$$126 \text{ mg} \div 140 \text{ mg/vial} = 0.9 \text{ vials; so 1 vial would be needed}$$

Reconstitute each vial with 7.2 mL of SWFI to yield 20 mg/mL. Direct the stream of diluent toward the side of the vial. Gently swirl to aid dissolution. ***Do not shake.*** Solution should be clear to slightly opalescent, colorless to slightly brown, and free of visible particulates. ***Do not freeze or expose to direct sunlight.*** Withdraw the calculated dose from the vial (126 mg [from the previous example] ÷ 20 mg/mL = 6.3 mL). This calculated dose must be further diluted in a minimum of 50 mL of NS, ½NS, or D5W to achieve a final concentration of 0.72 to 2.7 mg/mL. Gently invert to mix the solution. ***Do not shake. Do not freeze or expose to direct sunlight.***

Filters:

Use of a sterile, nonpyrogenic, low–protein-binding in-line or add-on filter (0.2- or 0.22-micron pore size) is required.

Storage:

Refrigerate vials at 2° to 8° C (36° to 46° F) in original carton to protect from light. Do not use beyond expiration date. ***Do not freeze. Do not shake.*** Reconstituted solution may be refrigerated for up to 48 hours or stored at RT up to a maximum of 8 hours before dilution. Discard vial when cumulative storage time before further dilution exceeds 48 hours. If not used immediately, store the fully diluted solutions depending on diluent according to the following chart.

Diluted Polatuzumab Vedotin-piiq Solution Storage Conditions[a]	
Diluent Used to Prepare Solution for Infusion	**Diluted Polatuzumab Vedotin-piiq Solution Storage Conditions**
NS	Up to 24 hours refrigerated at 2° to 8° C (36° to 46° F) **OR** Up to 4 hours at RT (9° to 25° C [47° to 77° F)
½NS	Up to 18 hours refrigerated at 2° to 8° C (36° to 46°F) **OR** Up to 4 hours at RT (9° to 25°C [47° to 77°F)
D5W	Up to 36 hours refrigerated at 2° to 8°C (36° to 46°F) **OR** Up to 6 hours at RT (9° to 25°C [47° to 77°F)

[a] To ensure product stability, do not exceed specified storage durations.

Limit transportation time (included in storage time) to 30 minutes at RT or 12 hours if refrigerated. Limit agitation of diluted product during preparation and transportation to administration site. Do not transport through an automated system (e.g., pneumatic tube or automated cart); agitation stress can result in aggregation. If transporting to a separate facility, remove air from the infusion bag to prevent aggregation. If air is removed, an infusion set with a vented spike is required to ensure accurate dosing during the infusion.

COMPATIBILITY

Manufacturer states, “Do not mix with or administer as an infusion with other drugs.”

RATE OF ADMINISTRATION

Must be administered using a dedicated infusion line equipped with a sterile, nonpyrogenic, low–protein-binding, in-line or add-on filter (0.2- or 0.22-micron pore size) and catheter.

Initial dose:

Administer polatuzumab as an IV infusion over 90 minutes. Monitor for infusion-related reactions during the infusion and for a minimum of 90 minutes after completion of the initial dose. If an infusion reaction occurs, interrupt the infusion and institute appropriate medical management.

Subsequent doses:

If the initial infusion was well tolerated, administer polatuzumab over 30 minutes and monitor during the infusion and for at least 30 minutes after completion of the infusion.

ACTIONS

A CD79b-directed antibody-drug conjugate (ADC) with activity against dividing B-cells. It consists of three components: (1) the humanized immunoglobulin G1 (IgG1) monoclonal antibody specific for human CD79b, (2) the small molecule antimitotic agent monomethyl auristatin E (MMAE), and (3) a protease-cleavable linker maleimidocaproyl-valine-citrulline-p-amino-benzyloxycarbonyl (mc-vc-PAB) that covalently attaches MMAE to the polatuzumab antibody. It binds to CD79b, a B-cell–specific surface protein, which is a component of the B-cell receptor. Upon binding CD79b, polatuzumab vedotin-piiq is internalized and enables intracellular delivery of MMAE. MMAE binds to microtubules and kills dividing cells by inhibiting cell division and inducing apoptosis. MMAE protein binding is 71% to 77%. Terminal half-life of the antibody-conjugated MMAE is approximately 12 days. Terminal half-life of unconjugated MMAE is approximately 4 days. Metabolism has not been studied in humans, but it is expected to undergo catabolism to small peptides, amino acids, unconjugated MMAE, and unconjugated MMAE-related catabolites. MMAE is a substrate for CYP3A4.

INDICATIONS AND USES

Used in combination with bendamustine (Treanda, Bendeka) and a rituximab product for the treatment of adult patients with relapsed or refractory diffuse large B-cell lymphoma (DLBCL), not otherwise specified, after at least two prior therapies. This indication was granted accelerated approval based on complete response rate. Continued approval may be contingent on verification and description of clinical benefit in a confirmatory trial.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ For IV infusion only; ***do not administer as an IV push or bolus***. ■ Has been known to cause peripheral neuropathy, including severe cases. Peripheral neuropathy is predominantly sensory; however, motor and sensorimotor peripheral neuropathy also occur. May occur as early as the first cycle of treatment and has a cumulative effect. Polatuzumab may also exacerbate pre-existing peripheral neuropathy. ■ Infusion-related reactions, including severe cases, have occurred. Delayed infusion reactions (as late as 24 hours after polatuzumab administration) have occurred. ■ Can cause serious or severe myelosuppression, including anemia, neutropenia, and thrombocytopenia. ■ Fatal and/or serious infections, including opportunistic infections such as sepsis, pneumonia (including *Pneumocystis jiroveci* and other fungal pneumonia), herpesvirus infection, and cytomegalovirus infection have occurred. ■ Progressive multifocal leukoencephalopathy (PML) has been reported. ■ May cause tumor lysis syndrome. Patients with a high tumor burden and rapidly proliferative tumor may be at increased risk. ■ Serious cases of hepatotoxicity consistent with hepatocellular injury, including elevations of transaminases and/or bilirubin, have occurred. Pre-existing liver disease, elevated baseline liver enzymes, and concomitant medications may increase the risk of hepatotoxicity. ■ Avoid administration in patients with moderate or severe hepatic impairment (bilirubin greater than 1.5 times the ULN); these patients are likely to have increased exposure to MMAE, which may increase the risk of adverse reactions. Has not been studied in these patients. ■ Has not been studied in patients with severe renal impairment or in patients with ESRD. ■ As with all therapeutic proteins, there is a potential for immunogenicity.

Monitor:

Obtain baseline and periodic CBC, including platelet count, liver enzyme studies, and bilirubin. ■ Cytopenias may require a delay, dose reduction, or discontinuation of therapy. Consider prophylactic granulocyte colony-stimulating factor administration; see Dose Adjustments. ■ Monitor for symptoms of peripheral neuropathy (e.g., burning sensation, dysesthesia, gait disturbance, hyperesthesia, hypoesthesia, neuropathic pain, paresthesia, and weakness). May require delay, dose reduction, or discontinuation of therapy; see Dose Adjustments. ■ Administer premedication and monitor for S/S of an infusion reaction (e.g., chills, dyspnea, fever, flushing, hypotension, and urticaria) during and after the infusion; see Rate of Administration. ■ Closely monitor for S/S of infection. ■ Monitor for new or worsening neurologic, cognitive, or behavioral changes. If PML is suspected, withhold therapy and any concomitant chemotherapy, and permanently discontinue if the diagnosis is confirmed. ■ Monitor for early S/S of tumor lysis syndrome (e.g., flank pain, hematuria, hyperuricemia, hyperkalemia, hyperphosphatemia, hypocalcemia). Maintain hydration. Uric acid–lowering drugs (e.g., allopurinol [Aloprim]) may be indicated.

Patient Education:

Verify pregnancy status of females of reproductive potential before initiating polatuzumab vedotin-piiq therapy. ■ Avoid pregnancy. Females of reproductive potential should use effective birth control during treatment and for at least 3 months after the final dose. Report a suspected pregnancy immediately. ■ Males with female sexual partners of reproductive potential should use effective contraception during treatment and for at least 5 months after the final dose. ■ May impair male fertility. ■ Promptly report S/S of infection (e.g., chills, cough, fever of 100.5° F or greater, pain with urination). ■ Promptly report S/S of peripheral neuropathy (e.g., muscle weakness, numbness or tingling of the hands or feet). ■ Promptly report S/S of an infusion reaction (e.g., breathing problems, chills, fever, or rash within 24 hours of an infusion). ■ Promptly report changes in mood or unusual behavior; confusion; thinking problems; loss of memory; changes in vision, speech, or walking; and decreased strength or weakness on one side of the body. ■ Promptly report symptoms of hepatotoxicity (abdominal pain, anorexia, dark urine, fatigue, jaundice). ■ Promptly report any bleeding/bruising. ■ Promptly report S/S of TLS (e.g., diarrhea, lethargy, nausea, vomiting). Periodic laboratory monitoring required. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy; based on its mechanism of action, it can cause fetal harm. ■ Discontinue breast-feeding during treatment and for at least 2 months after the final dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Numbers in clinical studies insufficient to determine whether elderly patients respond differently than younger subjects. Patients over 65 years of age had a higher incidence of serious adverse reactions.

DRUG/LAB INTERACTIONS

No clinical studies evaluating the drug-drug interaction potential of polatuzumab vedotin-piiq have been conducted. Another ADC drug that contains MMAE has the following drug interactions, and these interactions would likely result in similar effects on free MMAE and ADC. ■ Concomitant use with **a strong CYP3A4 inhibitor** (e.g., ketoconazole [Nizoral]) may increase free MMAE exposure, which may increase the incidence or severity of polatuzumab vedotin-piiq toxicities; monitor patients receiving ketoconazole or **other potent CYP3A4 inhibitors** (e.g., clarithromycin, itraconazole, nefazodone, saquinavir) closely for adverse reactions. ■ Concomitate use with rifampin, **a strong CYP3A4 inducer,** decreased MMAE and AUC and may reduce its effectiveness.

SIDE EFFECTS

The most common side effects reported include anemia, decreased appetite, diarrhea, fatigue, fever, neutropenia, peripheral neuropathy, pneumonia, and thrombocytopenia. Arthralgia; decreased phosphorus and potassium; dizziness; febrile neutropenia; hypoalbuminemia; hypocalcemia; hypokalemia; increased amylase, creatinine, ALT, AST, and lipase; leukopenia; lymphopenia; pancytopenia; sepsis; upper respiratory infections; vomiting; and decreased weight have also been reported. Serious adverse reactions include infusion-related reactions, hepatotoxicity, myelosuppression, peripheral neuropathy, progressive multifocal leukoencephalopathy, serious and opportunistic infections, and tumor lysis syndrome.

ANTIDOTE

Notify physician of all side effects. Treatment of most reactions will be supportive. Dose delay, dose modification, or discontinuation of therapy may be required in patients with severe or prolonged neutropenia, thrombocytopenia, peripheral neuropathy, or hepatotoxicity; see Dose Adjustments. G-CSF prophylaxis may be considered in patients with Grade 3 or Grade 4 neutropenia. If PML is suspected, hold polatuzumab vedotin-piiq. If PML is confirmed, discontinue polatuzumab vedotin-piiq. Interrupt or discontinue the infusion for an infusion-related reaction and institute appropriate medical management; see Dose Adjustments. Resuscitate as necessary.

POOLED PLASMA (HUMAN)

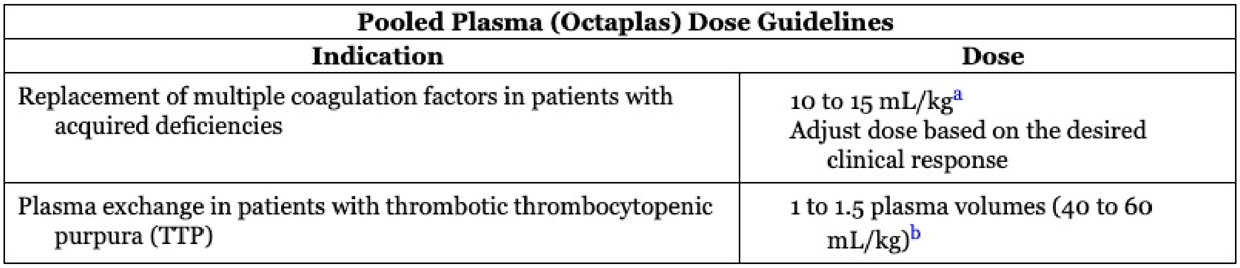
(**POOLD PLAZ**-ma **HUE**-man)
Octaplas
Plasma replacement and exchange

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Administer pooled plasma (Octaplas) based on ABO blood group compatibility.



Pooled Plasma (Octaplas) Dose Guidelines	
Indication	**Dose**
Replacement of multiple coagulation factors in patients with acquired deficiencies	10 to 15 mL/kg[a] Adjust dose based on the desired clinical response
Plasma exchange in patients with thrombotic thrombocytopenic purpura (TTP)	1 to 1.5 plasma volumes (40 to 60 mL/kg)[b]

[a] Patient's plasma coagulation factor levels should increase by approximately 15% to 25%. If hemostasis is not achieved, use higher doses.

[b] Completely replace plasma volume removed during plasmapheresis with Octaplas. In general, 1 to 1.5 plasma volumes corresponds to 40 to 60 mL/kg.

DOSE ADJUSTMENTS

Replacement of multiple coagulation factors in patients with acquired deficiencies:

Adjust dose based on desired clinical response.

DILUTION

Available as a frozen solution for infusion (specific to blood group A, B, AB, or O) containing 45 to 70 mg human plasma proteins per mL in a 200-mL volume. Administer after thawing using an infusion set with a filter. Avoid shaking.

To thaw in a water bath:

Thaw in outer wrapper for up to 30 minutes in a circulating water bath at 30° to 37° C (86° to 98.6° F). An overwrap bag may be used to provide further protection of contents if appropriate. Prevent water from contaminating the entry port. Thawing should not take more than 30 minutes.

To thaw by a dry tempering system:

See specific instructions in prescribing information.

Filters:

Administration through an in-line filter required.

Storage:

Store at −18° C (−0.4° F) or lower, protected from light. Thaw according to manufacturer's instructions. Use thawed product within 12 hours if stored at 2° to 4° C (35.6° to 39.2° F) or within 3 hours if stored at 20° to 25° C (68° to 77° F). Do not refreeze Octaplas. Discard unused product. Discard after expiration date on container label.

COMPATIBILITY

Manufacturer states, “Do not inject drugs containing calcium in the same IV line with Octaplas because precipitants may block the line.”

RATE OF ADMINISTRATION

Infusion rate should not exceed 0.020 to 0.025 mmol citrate/kg/min (i.e., less than 1 mL pooled plasma [Octaplas]/kg/min); see Precautions.

ACTIONS

Octaplas replaces human plasma proteins. It is a sterile, pyrogen-free, frozen solution of solvent/detergent (S/D) treated, pooled human plasma. It is manufactured from pooled plasma of a single ABO blood group (A, B, AB, or O). The finished product is tested for coagulation factors II, V, VII, VIII, X, and XI; protein C; protein S; alpha 2-antiplasmin (plasmin inhibitor); fibrinogen; and ADAMTS13. The content and distribution of plasma proteins in Octaplas are comparable to reference ranges for healthy blood donors, except for Protein S and alpha 2-antiplasmin, which are labile to S/D treatment and are controlled to ensure levels in the final product of equal to or greater than 0.4 IU/mL. Coagulation factor activities are controlled to obtain levels within the range of normal human plasma.

INDICATIONS AND USES

Replacement of multiple coagulation factors in patients who have acquired deficiencies due to liver disease or are undergoing cardiac surgery or liver transplant. ■ Plasma exchange in patients with thrombotic thrombocytopenic purpura (TTP).

CONTRAINDICATIONS

History of hypersensitivity to fresh frozen plasma (FFP) or plasma-derived products, including any plasma protein. ■ History of hypersensitivity reaction to Octaplas. ■ IgA deficiency. ■ Severe deficiency of Protein S.

PRECAUTIONS

Administration of Octaplas must be based on ABO blood group compatibility. Transfusion reactions can occur with ABO blood group mismatches. ■ Administer in a facility with equipment for monitoring the patient and responding to any medical emergency. ■ High infusion rates can induce hypervolemia with consequent pulmonary edema or cardiac failure. ■ Excessive bleeding due to hyperfibrinolysis can occur due to low levels of alpha 2-antiplasmin (plasmin inhibitor). ■ Thrombosis can occur due to low levels of Protein S. ■ Citrate toxicity can occur with volumes exceeding 1 mL/kg/min. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, hepatitis C). Numerous steps in the manufacturing process are used to make the potential for infection extremely remote.

Report suspected infections to manufacturer or FDA.

Monitor:

Replacement of multiple coagulation factors in patients with acquired deficiencies:

Obtain baseline aPTT, PT, and/or specific coagulation factors and monitor response with additional measurements.

All indications:

Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, chills, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, urticaria). ■ Monitor for S/S of pulmonary edema or cardiac failure. ■ Monitor for S/S of thrombosis in patients at risk. ■ Monitor for S/S of citrate toxicity (hypocalcemia [e.g., fatigue, muscle spasms, paresthesia]). Potential for citrate toxicity may be increased in patients with impaired hepatic function.

Liver transplant patients:

Monitor for S/S of excessive bleeding; may be due to hyperfibrinolysis.

Patient Education:

Promptly report S/S of a hypersensitivity reaction (e.g., chest pain, chills, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, urticaria). ■ Report development of edema or volume overload, including shortness of breath and/or difficulty breathing.

Maternal/Child:

Category C: use during pregnancy only if clearly needed. ■ Use caution in labor and delivery and during breast-feeding; safety and effectiveness unknown. ■ Safety and effectiveness for use in pediatric patients not evaluated.

Elderly:

Safety and effectiveness for use in geriatric patients not evaluated.

DRUG/LAB INTERACTIONS

May form a precipitate with **drugs containing calcium** (e.g., calcium gluconate).

SIDE EFFECTS

Headache, nausea, paresthesia, pruritus, and urticaria are most common. Anaphylactic shock, citrate toxicity, and severe hypotension are the most serious side effects reported.

Post-Marketing:

Abdominal pain, alkalosis, bronchospasm, cardiac arrest or failure, chest discomfort or pain, chills, circulatory overload, dyspnea, erythema, fever, hyperfibrinolysis, hypersensitivity reactions (including anaphylaxis), pulmonary edema, rash, respiratory arrest or failure, seroconversions (passive transfer of antibodies), tachycardia, tachypnea, thromboembolism, and vomiting have been reported.

ANTIDOTE

Notify the physician of all side effects. Minor side effects may be tolerated and treated symptomatically. For major side effects (e.g., hypervolemia, hyperfibrinolysis, thrombosis), discontinue Octaplas and treat symptomatically. Treat anaphylaxis immediately with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Treat citrate toxicity with calcium gluconate IV into another vein. Resuscitate as necessary.

PORFIMER SODIUM

(**POOR**-fih-mer **SO**-dee-um)
Photofrin
Photosensitizing agent
Antineoplastic
pH 7 to 8

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

A course is a two-stage process requiring administration of both drug and light.

Stage one:

Administration of porfimer:

A single IV injection of 2 mg/kg. No further injection of porfimer sodium should be given in any one course of therapy.

Stage two:

Illumination:

Illumination with nonthermal laser light at 40 to 50 hours post-injection.

Esophageal and Endobronchial Cancer

2 mg/kg of porfimer sodium as an IV injection. Approximately 40 to 50 hours after the injection, standard endoscopic techniques are used for light administration and débridement. The laser system must be approved for delivery of a stable power output at a wavelength of 630 ± 3 nm. Light is delivered to the tumor by cylindrical OPTIGUIDE fiber-optic diffusers passed through the operating channel of an endoscope/bronchoscope. The choice of diffuser tip length depends on the length of the tumor. Diffuser length should be sized to avoid exposure of nonmalignant tissue to light and to prevent overlapping of previously treated malignant tissue. A second laser light

application may be given 96 to 120 hours after injection. Before providing a second laser light treatment, the residual tumor should be gently débrided. Vigorous débridement may cause esophageal tumor bleeding; see Precautions.

Up to three courses may be given, but each must be separated by at least 30 days. Evaluate patients with esophageal cancer for the presence of a tracheoesophageal or bronchoesophageal fistula before each course. Evaluate all patients for possible erosion of the tumor into a major blood vessel.

Esophageal cancer:

2 mg/kg of porfimer sodium as an IV injection. A light dose of 300 joules/cm of diffuser length should be delivered by the specific process outlined previously. Light exposure time is set to 12 minutes and 30 seconds. Débridement of tumor may be performed 2 to 3 days later; see Precautions.

Endobronchial non–small-cell lung cancer:

2 mg/kg of porfimer sodium as an IV injection. A light dose of 200 joules/cm of diffuser length should be delivered by the specific process outlined previously. Light exposure time is set to 8 minutes and 20 seconds. Débridement of tumor should be performed 2 to 3 days later; see Precautions.

High-Grade Dysplasia (HGD in Barrett's Esophagus [BE])

2 mg/kg of porfimer sodium as an IV injection. Approximately 40 to 50 hours after the injection, administration of light should be delivered by an X-cell Photodynamic Therapy (PDT) balloon with a fiber-optic diffuser. The choice of fiber-optic/balloon diffuser combination will depend on the length of Barrett's mucosa to be treated (see manufacturer's information). The objective of therapy is to expose and treat all areas of HGD and the entire length of Barrett's esophagus. The light dose administered is 130 joules/cm of diffuser length. Acceptable light intensity for the balloon/diffuser combinations ranges from 200 to 270 mW/cm of diffuser. Treatment time is dependent on the fiber-optic/balloon diffuser combination used (see manufacturer's information). A maximum of 7 cm of esophageal mucosa may be treated at the first light session. If possible, the area treated should include normal tissue margins of a few millimeters at both the proximal and distal ends. Nodules are pretreated at a light dose of 50 joules/cm of diffuser length with a short (2.5 cm) fiber-optic diffuser placed directly against the nodule. A second laser light application may be given to a previously treated segment that shows a "skip" area using a 2.5-cm fiber-optic diffuser at a light dose of 50 joules/cm of the diffuser length. Patients with Barrett's esophagus greater than 7 cm should have the remaining untreated length of Barrett's epithelium treated with a second PDT course at least 90 days later. See Precautions.

Up to 3 courses (each separated by 90 days) may be given to a previously treated segment that still shows high-grade dysplasia, low-grade dysplasia, or Barrett's metaplasia, or to a new segment if the initial Barrett's segment was greater than 7 cm in length.

DOSE ADJUSTMENTS

No adjustments required.

DILUTION

Specific techniques required; see Precautions. Prepare immediately before use. Each vial of porfimer sodium must be reconstituted with 31.8 mL of D5W or NS. Concentration will be 2.5 mg/mL. Shake well until dissolved. An opaque solution; detection of particulate matter by visual inspection is difficult. Withdraw desired dose. Must be protected from bright light and used immediately.

Storage:

Store unopened vials at CRT in carton to protect from light.

COMPATIBILITY

Manufacturer states, “Do not mix porfimer sodium with other drugs in the same solution.”

RATE OF ADMINISTRATION

A single dose equally distributed over 3 to 5 minutes.

ACTIONS

The first light-activated drug (photosensitizing agent) for use in photodynamic therapy (PDT) to be approved in the United States. Treatment consists of a two-step process involving administration of drug and light. Cytotoxic and antitumor actions are light dependent and oxygen dependent and are the result of the propagation of radical reactions. PDT with porfimer causes direct intracellular damage by initiating radical chain reactions that damage intracellular membranes and mitochondria. After IV infusion of drug, it is allowed to circulate. It accumulates and is retained in tumors, skin, and organs of the reticuloendothelial system (e.g., liver, spleen) while largely clearing from other tissues. Has no apparent effect on tumors until it is activated by selective delivery of light (usually 40 to 50 hours postinfusion). Light activation induces a photochemical, not a thermal, effect that produces an active form of oxygen and releases thromboxane A_2. This process causes vasoconstriction, activation and aggregation of platelets, and increased clotting that contribute to ischemic necrosis leading to tissue and tumor death. The necrotic reaction and associated inflammatory response may evolve over several days. In patients with esophageal cancer, ability to swallow is improved, as is quality of life. Elimination half-life is very prolonged, up to several weeks. Highly protein bound.

INDICATIONS AND USES

Palliative treatment of patients with completely obstructing esophageal cancer or partially obstructing esophageal cancers that are unsuitable for treatment with thermal laser therapy. ■ Treatment of microinvasive endobronchial non–small-cell lung cancer (NSCLC) in patients for whom surgery and radiotherapy are not indicated. ■ Reduction of obstruction and palliation of symptoms in patients with completely or partially obstructing endobronchial non–small-cell lung cancer. ■ Ablation of high-grade dysplasia (HGD) of Barrett’s esophagus patients who do not undergo esophagectomy.

Unlabeled uses:

Treatment of AIDS-related cutaneous Kaposi's sarcoma, primary or recurrent basal cell carcinoma, and squamous cell carcinoma.

CONTRAINDICATIONS

Known allergies to porphyrins, an existing tracheoesophageal or bronchoesophageal fistula, porphyria, or tumors eroding into a major blood vessel. ■ Photodynamic therapy (PDT) is not suitable for emergency treatment of patients with severe acute respiratory distress caused by an obstructing endobronchial lesion because 40 to 50 hours are required between injection with porfimer sodium and laser light treatment. ■ PDT is not suitable for patients with esophageal or gastric varices or for patients with esophageal ulcers greater than 1 cm in diameter.

PRECAUTIONS

Use rubber gloves and eye protection during preparation and administration. Avoid any skin or eye contact since that area will become photosensitive. Wipe up spills with a damp cloth. Dispose of all contaminated materials in a polyethylene bag to avoid accidental contact by others. Protection from light will be necessary if accidental exposure or overexposure occurs. See process in Patient Education. ■ Administered by or under the direction of the physician specialist with appropriate knowledge of the selected laser system. Facilities for monitoring the patient and responding to any medical emergency must be available. ■ Requires laser systems and a fiber-optic diffuser to activate. The FDA has approved several photodynamic lasers and the OPTIGUIDE fiber-optic diffuser for use with porfimer sodium. ■ Avoid exposure of skin and eyes to direct sunlight or bright indoor light; see Patient Education. ■ Porfimer elimination may be prolonged in patients with hepatic or renal impairment, and they may require longer precautionary measures for photosensitivity. ■ In the original studies for esophageal tumors, some experienced investigators indicated that natural sloughing action in the esophagus might be sufficient and débridement could needlessly traumatize the area. However, débridement may be performed after each light activation to minimize the potential for obstruction caused by necrotic debris. ■ A minimum of 4 weeks after completion of radiation therapy is recommended before treatment with PDT. This allows the acute inflammation produced by radiotherapy to subside. ■ 2 to 4 weeks should be allowed after PDT is complete before beginning any radiotherapy. ■ Thromboembolic events can occur following PDT with porfimer. More common in patients with other risk factors for thromboembolism (e.g., advanced cancer, cardiovascular disease, after a major surgery, or prolonged immobilization).

Esophageal tumors:

Not recommended if the esophageal tumor is eroding into the trachea or bronchial tree; tracheoesophageal or bronchoesophageal fistula may result from treatment. Serious and sometimes fatal gastrointestinal and esophageal necrosis and perforation can occur after treatment. ■ Use extreme caution in patients with esophageal varices. Light should not be given directly to the variceal area because of the high risk of bleeding.

Endobronchial cancer:

Interstitial fiber placement is preferred to intraluminal activation in noncircumferential endobronchial tumors that are soft enough to penetrate. Results in less exposure of the normal bronchial mucosa to light. ■ Patients with obstructing lung cancer who have received prior radiation therapy or who have tumors that are large, centrally located, cavitating, or extensive and extrinsic to the bronchus have a higher incidence of fatal hemoptysis. ■ An endobronchial tumor that invades deeply into the bronchial wall may create a fistula as the tumor resolves. ■ Use with extreme caution in endobronchial tumors located where treatment-induced inflammation could obstruct the airway (e.g., long or circumferential tumors of the trachea, tumors of the carina that involve both mainstem bronchi circumferentially, or circumferential tumors in the mainstem bronchus in patients with prior pneumonectomy).

HGD in Barrett's esophagus:

Before initiating treatment with porfimer PDT, a diagnosis of HGD in Barrett's esophagus should be confirmed by a GI pathologist. ■ Long-term effect of PDT on HGD in Barrett's esophagus is unknown. There may be a risk of leaving cancerous cells behind or of leaving residual abnormal epithelium beneath the new squamous cell epithelium. ■ Esophageal strictures are a common adverse effect seen in patients treated with PDT for HGD in Barrett's esophagus. Nodule pretreatment and re-treatment of the same mucosal segment more than once may influence the risk of developing an esophageal stricture. Usually occur within 6 months following PDT. May be managed with esophageal dilation; several dilations may be required.

Monitor:

Obtain baseline CBC and monitor for anemia due to tumor bleeding. ■ Prevent extravasation at the injection site. Should extravasation occur, area must be protected from light. ■ Opiates may be required to control pain. ■ Observe patients carefully; most are critically ill, and many complications could occur. Monitor patients with ***endobronchial tumors*** closely between the laser light therapy and the mandatory débridement bronchoscopy for any evidence of respiratory distress, inflammation, mucositis, or necrotic debris that may cause obstruction of the airway. Immediate bronchoscopy may be required to remove secretions and debris to open the airway. ■ Monitor for hemoptysis; may be a sign of progressive disease, or may result from resolution of a tumor that has eroded into a pulmonary artery. ■ In patients who have received PDT for ***HGD in Barrett's esophagus,*** endoscopic biopsy surveillance should be conducted every 3 months until 4 consecutive negative evaluations for HGD have been recorded. Further follow-up should be performed every 6 to 12 months. ■ Photosensitivity not transferable through skin to caregivers. ■ See Precautions, Patient Education, and Drug/Lab Interactions.

Patient Education:

Must observe precautions to avoid exposure of skin and eyes to direct sunlight or bright indoor light for at least 30 days. Some patients may remain photosensitive for up to 90 or more days. Photosensitivity is due to residual drug, which is present in all parts of the skin. Ambient indoor light is beneficial as it gradually inactivates the remaining drug through a photobleaching reaction. Do not remain in a darkened room. Do expose skin to ambient indoor light. Avoid bright indoor light from examination lamps, dental lamps, operating room lamps, and unshaded light bulbs. Limit time outdoors to necessary excursions, and completely cover body with clothing and shade face before going out. Conventional ultraviolet sunscreens are of no value because photoactivation is caused by visible light, not UV rays. Eyes will be sensitive to sun, bright lights, and car headlights; wear dark sunglasses with an average white light transmittance of less than 4%. After several weeks and before exposing any area of skin to direct sunlight or bright indoor light, test a small area of skin (not the face) for residual photosensitivity. Expose the small area of skin for 10 minutes. If no photosensitivity reaction (redness, swelling, or blistering) occurs within 24 hours, gradually resume normal outdoor activities. Exercise caution and increase skin exposure gradually. If some photosensitivity reaction occurs, continue precautions for 2 more weeks and then retest. Retest level of photosensitivity if traveling to a different geographic area with greater sunshine. ■ Report chest pain (caused by inflammatory response within the area of treatment); may require prescription pain medication. ■ Avoid pregnancy. Effective contraception necessary for women of reproductive potential during treatment and for 5 months after the last dose. Men with female partners of reproductive potential should use condoms during treatment and for 5 months after the last dose.

Maternal/Child:

Based on animal studies, porfimer sodium can cause fetal harm. Effective contraception necessary. Has caused maternal and fetal toxicity in rats and rabbits (increased resorptions, decreased litter size, and reduced fetal body weight). ■ Discontinue breast-feeding during treatment and for 5 months after the last dose. Serious reactions could occur in the infant. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Dose modification based on age is not required.

DRUG/LAB INTERACTIONS

No specific studies have been completed, but the following interactions are likely to occur. ■ Use with **other photosensitizing agents** (e.g., griseofulvin, fluoroquinolones [e.g., ciprofloxacin], phenothiazines [e.g., prochlorperazine], sulfonamides [sulfisoxazole, ophthalmic solutions (AK-Sulf)], sulfonylurea hypoglycemic agents [tolbutamide], tetracyclines [doxycycline], thiazide diuretics [chlorothiazide]) could increase the photosensitivity reaction. ■ Antitumor activity may be decreased by **dimethyl sulfoxide, beta-carotene, ethanol, formate, mannitol.** ■ Antitumor activity may also be decreased by **allopurinol**, **calcium channel blockers** (e.g., diltiazem), **prostaglandin synthesis inhibitors** (NSAIDs [e.g., ibuprofen, naproxen]), **and tissue ischemia.** ■ Effectiveness may be reduced by **drugs that decrease clotting, vasoconstriction** (e.g., nicardipine), **or platelet aggregation** (e.g., dipyridamole). ■ **Glucocorticoid hormones** (e.g., dexamethasone) given before or with PDT may reduce the effectiveness of porfimer by inhibiting the production of thromboxane A_2.

SIDE EFFECTS

All diagnoses:

May cause constipation. Most toxicities are local effects in the region of illumination and occasionally in surrounding tissues. Usually an inflammatory response induced by the photodynamic effects. Photosensitivity reactions occurred in 20% of patients in clinical studies. Reactions were usually mild to moderate erythema, but also included blisters, burning sensation, itching, and swelling. Less common skin manifestations included increased hair growth, skin discoloration, skin nodules, increased wrinkles, and skin fragility. Cases of fluid imbalance and thromboembolic events have been reported. Cataracts have been reported in one man with a family history of cataracts. Relationship to porfimer sodium unknown.

Post-Marketing:

Infusion reactions (bradycardia, dizziness, hypertension, hypotension, urticaria).

Esophageal tumors:

Bronchoesophageal or tracheoesophageal fistula can occur as a result of the disease or treatment, including débridement. Abdominal pain, anemia (more prevalent if tumor is located in the lower third of the esophagus), anorexia, arrhythmias (atrial fibrillation [more prevalent if tumor is located in the middle third of the esophagus], tachycardia), candidiasis, chest pain, coughing, dyspepsia, dysphagia, dyspnea, edema, eructation, esophageal edema (more prevalent if tumor is located in the upper third of the esophagus), esophageal tumor bleeding, esophageal stricture, esophagitis, fever, hematemesis, hypertension, hypotension, insomnia, nausea, pleural effusion, and vomiting may occur, as well as numerous others.

Endobronchial tumors:

Coughing, dysphagia, dyspnea (may be life threatening), mucositis reaction (e.g., edema, exudate, and mucous plug obstruction), stricture, ulceration. Fatal hemoptysis has occurred (higher incidence in patients who have received radiation therapy).

High-grade dysplasia (HGD in Barrett's esophagus [BE]):

Esophageal narrowing and esophageal stricture are common side effects and may require multiple dilations. Other side effects may include abdominal pain, anorexia, anxiety, arthralgia, back pain, chest discomfort or pain, dehydration, depression, diarrhea, dyspepsia, dysphagia, dyspnea, eructation, esophageal pain, fatigue, fever, headache, hiccups, hypertension, infections (bronchitis, sinusitis), insomnia, nausea and vomiting, odynophagia (pain on swallowing), pleural effusion.

ANTIDOTE

If an overdose of porfimer sodium is given, do not give the laser light treatment. Porfimer sodium is not dialyzable. Increased side effects and damage to normal tissue can be expected if an overdose of light is given. Keep physician informed of all side effects; most will be treated symptomatically. Some may be life threatening. Respiratory obstruction may require immediate bronchoscopy and removal of the obstruction with suction or forceps. Stent placement may be required in endobronchial stricture. Chest pain may require the use of opiates.

POSACONAZOLE

(**POE**-sa-**KON**-a-zole)
Noxafil
Antifungal
(azole derivative)
pH 2.6

USUAL DOSE

Pretreatment:

Should be administered via a central venous line (e.g., central venous catheter or peripherally inserted central catheter [PICC]); see Precautions. Correct calcium, magnesium, and potassium deficiencies before initiating posaconazole. Baseline studies indicated; see Monitor.

Posaconazole dose:

300 mg as an IV infusion twice a day on the first day. Beginning on the second day, administer 300 mg once each day. Duration of treatment is based on recovery from immunosuppression or neutropenia and on clinical response.

Oral formulations may be substituted when appropriate.

DOSE ADJUSTMENTS

No dose adjustment is required in patients with an estimated glomerular filtration rate (eGFR) of 50 mL/min or greater; however, the intravenous vehicle Betadex Sulfobutyl Ether Sodium (SBECD) accumulates in patients with an eGFR of less than 50 mL/min. Use of oral posaconazole is recommended in these patients; see Precautions and Monitor. ■ No dose adjustment recommended in patients with mild to severe hepatic impairment (Child-Pugh Class A, B, or C); however, specific studies have not been conducted. ■ No dose adjustment indicated based on age, race, or gender. ■ Patients weighing more than 120 kg may have lower posaconazole levels. Monitor for breakthrough fungal infections.

DILUTION

Bring the 300-mg vial of posaconazole solution to RT. Aseptically transfer the contents of the vial (16.7 mL [18 mg/mL]) to a bag or bottle of ½NS, NS, D5W, D5½NS, D5NS, or D5W with 20 mEq KCl. Final concentration should be 1 to 2 mg/mL. Solution will be colorless to yellow.

Filters:

Must be administered through a 0.22-micron polyethersulfone (PES) or polyvinylidene difluoride (PVDF) filter.

Storage:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Contains no preservatives; immediate use of the admixed product is preferred, but it may be refrigerated for up to 24 hours. Discard any unused solution.

COMPATIBILITY

Posaconazole should be prepared only in the solutions listed under Dilution. Use of other infusion solutions may result in particulate formation. Do not coadminister any products or diluents that are not listed by the manufacturer.

Manufacturer states that posaconazole is **compatible** with and can be infused at the same time through the same IV line **(Y-site)** as solutions listed under Dilution and the following products prepared in D5W or NS: amikacin, caspofungin, ciprofloxacin, daptomycin, dobutamine, famotidine, filgrastim, gentamicin, hydromorphone, levofloxacin, lorazepam, meropenem, micafungin, morphine, norepinephrine, potassium chloride, and vancomycin.

Manufacturer states that posaconazole is **incompatible** with and must not be diluted with LR, D5LR, and 4.2% sodium bicarbonate.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Do not administer as an IV bolus. Administer through a 0.22-micron polyethersulfone (PES) or polyvinylidene difluoride (PVDF) filter.

Central venous catheter:

Each dose as an IV infusion equally distributed over 90 minutes.

Single or initial dose (if a central venous catheter is not available):

A single dose as an IV infusion equally distributed over 30 minutes.

ACTIONS

An azole antifungal agent. It blocks the synthesis of ergosterol, a key component of the fungal cell membrane, by inhibiting the cytochrome P_{450}–dependent enzyme lanosterol 14α-demethylase, which is responsible for the conversion of lanosterol to ergosterol. The depletion of ergosterol results in weakening of the structure and function of the fungal cell membrane (antifungal activity). Primarily circulates as the parent compound in plasma. Highly bound to human plasma proteins, predominantly albumin. Primarily metabolized via UDP glucuronidation and is a substrate for P-glycoprotein (P-gp) efflux. Mean terminal half-life is 27 hours. Primarily eliminated in feces as parent compound. Some minor excretion of metabolites occurs in urine and feces.

INDICATIONS AND USES

Prophylaxis of invasive *Aspergillus* and *Candida* infections in patients 18 years of age and older who are at high risk for developing these infections due to being severely immunocompromised, such as hematopoietic stem cell transplant (HSCT) recipients with graft-versus-host disease (GVHD) or patients with hematologic malignancies with prolonged neutropenia from chemotherapy.

CONTRAINDICATIONS

Known hypersensitivity to posaconazole or other azole antifungal agents. ■ Concomitant administration with sirolimus. ■ Concomitant administration with CYP3A4 substrates that prolong the QT interval (e.g., pimozide, quinidine). ■ Coadministration with HMG-CoA reductase inhibitors primarily metabolized through CYP3A4 (e.g., atorvastatin, simvastatin). ■ Coadministration with ergot alkaloids. ■ See Drug/Lab Interactions.

PRECAUTIONS

Should be administered via a central venous line (e.g., central venous catheter or peripherally inserted central catheter [PICC]). If necessary, the initial dose may be administered through a peripheral IV line in advance of central venous line placement or to bridge the period during which a central venous line is replaced or is in use for other treatment. In clinical trials, multiple peripheral infusions resulted in infusion site reactions. ***Do not administer as an IV bolus.*** ■ Avoid use of the IV formulation in patients with moderate or severe renal impairment (eGFR less than 50 mL/min) unless an assessment of the benefit versus risk to the patient justifies use; see Dose Adjustments. ■ Concomitant administration with cyclosporine or tacrolimus increases the whole blood trough concentrations of these calcineurin inhibitors; see Drug/Lab Interactions. Nephrotoxicity and leukoencephalopathy (including deaths) have been reported in patients with elevated cyclosporine or tacrolimus concentrations. ■ Has been associated with prolongation of the QT interval. Torsades de pointes has been reported. Use with caution in patients with potentially proarrhythmic conditions. Do not administer with drugs that are known to prolong the QTc interval and are metabolized through CYP3A4. Correct electrolyte abnormalities before administration. ■ Hepatic toxicity (e.g., mild to moderate elevations in ALT, AST, alkaline phosphatase, total bilirubin, and/or clinical hepatitis) has been reported. Cases of more severe hepatic reactions, including cholestasis or hepatic failure (including deaths), have been reported in patients with serious underlying medical conditions (e.g., hematologic malignancy). Consider discontinuing posaconazole in patients who develop S/S of hepatic toxicity. ■ Use with midazolam may prolong hypnotic and sedative effects of midazolam; see Drug/Lab Interactions. Benzodiazepine receptor antagonists should be available (e.g., flumazenil). ■ Concomitant administration with vincristine has been associated with neurotoxicity and other serious adverse reactions, including seizures, peripheral neuropathy, syndrome of inappropriate antidiuretic hormone secretion, and paralytic ileus. Reserve azole antifungals (including posaconazole) for patients receiving a vinca alkaloid (including vincristine) who have no alternative antifungal treatment options; see Drug/Lab Interactions. ■ Hypersensitivity reactions have been reported. ■ Cross-resistance between azoles may occur; clinical significance unknown.

Monitor:

Obtain baseline CBC, platelets, serum creatinine, and electrolytes. Monitor as indicated during therapy. ■ Electrolyte disturbances, especially those involving potassium, magnesium, or calcium levels, should be monitored and corrected as necessary before and during therapy. ■ Obtain baseline liver function tests and monitor throughout treatment. If elevations in ALT, AST, alkaline phosphatase, or total bilirubin occur, monitor for S/S of more severe hepatic injury. Consider discontinuation of posaconazole with the development of clinical S/S consistent with liver disease that may be attributable to posaconazole. ■ Monitor serum creatinine levels closely in patients with moderate or severe renal impairment who receive posaconazole. ■ Monitor for S/S of hypersensitivity reactions (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Closely monitor patients weighing more than 120 kg for breakthrough fungal infections; they may have lower posaconazole plasma drug exposure. ■ See Drug/Lab Interactions.

Patient Education:

Review of health history and complete medication profile, including over-the-counter medicines, vitamins, and herbal supplements, is imperative. ■ Do not start a new medicine without consulting your health care provider. ■ Review FDA-approved Patient Information. ■ Use of effective birth control may be indicated. ■ Promptly report S/S of a hypersensitivity reaction (e.g., itching, hives, shortness of breath). ■ Promptly report S/S of liver toxicity (e.g., feeling very tired, flu-like symptoms, itchy skin, nausea or vomiting, yellowing of the eyes). ■ Report a change in heart rate or rhythm. ■ Additional precautions may be required with transfer to oral posaconazole.

Maternal/Child:

May cause fetal harm when administered to pregnant women. ■ There are no data on the presence of posaconazole in human milk, the effects on the breast-fed infant, or the effects on milk production. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly:

Safety profile similar to younger adults; dose adjustment not indicated.

DRUG/LAB INTERACTIONS

Interactions are numerous. Review of drug profile by pharmacist imperative.

Primarily metabolized via **UDP glucuronosyltransferase** and is a **substrate of P-glycoprotein (P-gp) efflux. Inhibitors or inducers** of these clearance pathways may affect posaconazole plasma concentrations. ■ A strong **inhibitor of CYP3A4**. May increase plasma concentrations of drugs predominantly metabolized by CYP3A4. ■ Concomitant administration with **sirolimus** is ***contraindicated.*** Blood concentrations of sirolimus may be increased approximately ninefold and result in sirolimus toxicity. ■ Concomitant administration with **CYP3A4 substrates that prolong the QT interval** (e.g., pimozide, quinidine) is ***contraindicated.*** May result in increased plasma concentrations of the CYP3A4 substrates, leading to QTc prolongation and torsades de pointes. ■ Coadministration with **HMG-CoA reductase inhibitors primarily metabolized through CYP3A4** (e.g., atorvastatin, lovastatin, simvastatin) is ***contraindicated.*** Increased plasma concentrations of these drugs can lead to rhabdomyolysis. ■ Coadministration with **ergot alkaloids** is ***contraindicated.*** Increased plasma concentration of ergot alkaloids may lead to ergotism. ■ Concomitant administration with **cyclosporine** or **tacrolimus** increases the whole blood trough concentrations of these calcineurin inhibitors. Reduce dose of cyclosporine to approximately three-fourths of the original dose and reduce the dose of tacrolimus to approximately one-third of the original dose. Monitor concentrations frequently during coadministration and after discontinuation of posaconazole. ■ Concomitant use with **midazolam** increases midazolam plasma concentrations by approximately fivefold and prolongs the hypnotic and sedative effects of midazolam. Concurrent use with **other benzodiazepines** metabolized by CYP3A4 (e.g., alprazolam) could also result in increased plasma concentrations. If concomitant administration of these drugs with posaconazole is indicated, monitor patients closely, and a benzodiazepine receptor antagonist (e.g., flumazenil) should be available. ■ **Efavirenz, rifabutin,** and **phenytoin** induce UDP-glucuronidase and significantly decrease posaconazole plasma concentrations. Avoid concomitant use unless benefit outweighs risks. Monitor patients for breakthrough fungal infections. ■ **Rifabutin** is metabolized by CYP3A4; coadministration with posaconazole increases rifabutin plasma concentrations. If concomitant administration is indicated, monitor closely for breakthrough fungal infections and monitor full blood counts to avoid side effects (e.g., uveitis, leukopenia) from increased rifabutin plasma concentrations. ■ **Phenytoin** is metabolized by CYP3A4; coadministration with posaconazole increases phenytoin plasma concentrations. If concomitant administration is indicated, monitor closely for breakthrough fungal infections and monitor phenytoin concentrations frequently. Consider dose reduction of phenytoin. ■ **Atazanavir** and **ritonavir** are metabolized by CYP3A4, and posaconazole increases their plasma concentrations. Monitor frequently for adverse effects and toxicity of atazanavir and ritonavir if coadministration is indicated. ■ Concomitant administration with **fosamprenavir** may decrease posaconazole plasma concentrations; monitoring for breakthrough fungal infections is recommended. ■ **Vinca alkaloids** (e.g., vincristine, vinblastine) are substrates of CYP3A4; posaconazole may increase their plasma concentrations, leading to neurotoxicity and other adverse drug reactions. Reserve posaconazole for patients receiving a vinca alkaloid who have no alternative antifungal treatment options; see Precautions. ■ Posaconazole may increase the plasma concentrations of **calcium channel blockers** metabolized by CYP3A4. If coadministration is indicated, monitor frequently for side effects associated with calcium channel blockers. Dose reduction of the calcium channel blocker may be indicated. ■ May increase plasma concentrations of **digoxin**.

SIDE EFFECTS

Diarrhea, fever, hypokalemia, and nausea and vomiting are most common. The most serious side effects include arrhythmias and QT prolongation, hepatic toxicity, and hypersensitivity (including anaphylaxis). Abdominal pain, anemia, chills, constipation, cough, decreased appetite, dyspnea, epistaxis, fatigue, headache, hypertension, hypomagnesemia, peripheral edema, petechiae, rash, and thrombocytopenia have also been reported. Several other clinically significant adverse reactions were reported in fewer than 5% of patients during clinical trials.

Post-Marketing:

Pseudoaldosteronism.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. If a hypersensitivity reaction occurs, discontinue the infusion and treat with oxygen, epinephrine, antihistamines, corticosteroids, or bronchodilators as indicated. Consider discontinuation of posaconazole if liver function tests are elevated and/or clinical S/S of liver disease attributable to posaconazole develop. No known specific antidote. Not removed by hemodialysis. Resuscitate as indicated.

POTASSIUM ACETATE AND POTASSIUM CHLORIDE

(po-**TASS**-ee-um **AS**-ah-tayt, po-**TASS**-ee-um **KLOR**-eyed)
Electrolyte replenisher
pH 4 to 8

USUAL DOSE

Concentrated potassium solutions must be diluted before administration; direct injection of any concentrated solution can be instantly fatal.

Maintenance potassium requirements should be incorporated into maintenance IV fluids. Intermittent IV potassium administration should be reserved for treatment of hypokalemia when the oral route is not feasible.

Dose and rate of administration are dependent on specific patient condition. Starting dose based on losses, desired replacement, or maintenance.

Normal daily requirements:

Adults:

40 to 80 mEq/24 hr.

Serum potassium level greater than 2.5 mEq/L:

Rate should usually not exceed 10 mEq/hr or 200 mEq over a 24-hour period.

Serum potassium level less than 2 mEq/L and hypokalemia is a threat (e.g., potassium level less than 2 mEq/L and ECG changes and/or muscle paralysis):

Rates up to 40 mEq/hr or 400 mEq over a 24-hour period can be administered. Continuous monitoring of ECG and frequent serum potassium determinations are required to prevent hyperkalemia and cardiac arrest.

PEDIATRIC DOSE

See comments under Usual Dose.

Normal daily requirements:

Newborn: 2 to 6 mEq/kg/24 hr. ***Other pediatric patients:*** 2 to 3 mEq/kg/24 hr.
Another source recommends:

Maintenance:

2 to 4 mEq/kg/day.

Treatment of hypokalemia:

0.5 to 1 mEq/kg/dose infused at a rate of 0.5 mEq/kg/hr or less (maximum recommended single dose is 40 mEq). ECG and serum potassium monitoring recommended. Rates of 1 mEq/kg/hr have been used in critical care settings or critical care situations.

Potassium concentrate products may contain aluminum; see Precautions and Maternal/Child.

DOSE ADJUSTMENTS

Careful dose selection and adjustment is required in high-risk patients; see Precautions. ■ Reduce dose in impaired renal function. ■ Lower-end initial doses may be appropriate in the elderly based on potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Available in multiple forms. ***Direct injection of any concentrated solution can be instantly fatal. Potassium chloride or acetate concentrate (2 mEq/mL) must be diluted in a larger volume of suitable IV solution and given as an infusion.*** Compatible in most commonly used IV solutions; see chart on inside back cover. 40 mEq/L is the preferred dilution. 80 mEq/L is the usual maximum concentration and must be administered with caution. Avoid layering of potassium by thoroughly agitating the prepared IV solution. Also available as premixed concentrated solutions for administration via a peripheral or central line (route is dependent on concentration) and as premixed large volume solutions. In replacement therapy more concentrated solutions may be used and must be administered with caution.
40 mEq/100 mL is commonly used and must be controlled by an infusion pump and administered via a central line. In severe hypokalemia, solutions without dextrose are

preferred (dextrose might decrease serum potassium level). Use only clear solutions. Check labels for aluminum content; see Precautions.

Storage:

Most products may be stored at RT or CRT. See specific manufacturer requirements.

COMPATIBILITY

One manufacturer of premixed, highly concentrated solutions says, “Do not add supplementary medication.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Because pain associated with peripheral infusion of potassium has been reported, administration via a central route is recommended whenever possible. Higher concentrations (40 mEq/100 mL) should be exclusively administered via a central line.

In general, a maximum of 10 mEq/hr of potassium chloride in any given amount of infusion fluid should not be exceeded. With serious potassium depletion (serum potassium under 2 mEq/L), 20 to 40 mEq/hr has been given with extreme caution and patient must be on cardiac monitor and given via central line. Use of an infusion pump is recommended in all situations. Too-rapid infusion of hypertonic solutions may cause local pain and, rarely, vein irritation. Adjust rate of administration according to patient tolerance.

Pediatric rate:

Usual rate is 0.5 mEq/kg/hr (up to 10 to 20 mEq/hr) or less. Infusion rates of up to 1 mEq/kg/hr (up to 40 mEq/hr) have been used in critical care settings.

ACTIONS

Potassium:

Principal cation of intracellular fluid. Important for maintenance of body fluid composition and electrolyte balance. Participates in carbohydrate utilization and protein synthesis. Critical in the regulation of nerve conduction and muscle contraction, particularly in the heart. The normal serum potassium range is 3.5 to 5 mEq/L. The kidney normally regulates potassium balance but does not conserve potassium balance as well as or as promptly as it conserves sodium. Excreted in urine.

Chloride:

The major extracellular anion. Closely follows the metabolism of sodium. Changes in the acid-base balance of the body are reflected by the changes in chloride concentration.

Acetate:

An alternate source of bicarbonate by metabolic conversion in the liver.

INDICATIONS AND USES

Prevention or treatment of potassium deficiency when oral replacement is not feasible. ■ Potassium chloride in dextrose solutions is indicated as a source of water, electrolytes, and calories.

CONTRAINDICATIONS

Hyperkalemia, renal failure, and any condition in which potassium retention is present.

Potassium chloride:

Known hypersensitivity to potassium chloride.

Potassium acetate:

Adrenal insufficiency.

PRECAUTIONS

Highly concentrated, ready-to-use potassium chloride injection is intended for the maintenance of serum potassium levels and for potassium supplementation in fluid-restricted patients who cannot accommodate additional volumes of fluid associated with potassium solutions of lower concentration. ■ To avoid potassium intoxication, do not infuse potassium infusions rapidly. ■ Administer with extreme caution, if at all, to patients with conditions predisposing to hyperkalemia and/or associated with increased sensitivity to potassium (e.g., acute dehydration, certain cardiac disorders such as CHF or AV block, extensive tissue injury or burns, severe renal impairment, potassium-aggravated skeletal muscle channelopathies [e.g., hyperkalemic periodic paralysis, paramyotonia congenita, and potassium-aggravated myotonia/paramyotonia]). ■ Administer with caution to patients who are at risk for experiencing hyperosmolality or acidosis, patients who are undergoing correction of alkalosis (conditions associated with a shift of potassium from intracellular to extracellular space), and patients treated concurrently or recently with agents or products that can cause hyperkalemia; see Drug/Lab Interactions. ■ Use solutions containing potassium with caution in patients with cardiac disease, particularly in the presence of renal disease. Cardiac monitoring is recommended. ■ Administration of concentrated potassium solutions can cause cardiac conduction disorders (including complete heart block) and other cardiac arrhythmias at any time during infusion. Continuous cardiac monitoring is performed to aid in the detection of cardiac arrhythmias. Mild or moderate hyperkalemia may be asymptomatic and may be manifested only by increased serum potassium concentrations and, possibly, characteristic ECG changes. However, fatal arrhythmias can develop at any time during hyperkalemia. ■ Potassium chloride may cause hyponatremia. Risk is increased in pediatric patients, elderly patients, postoperative patients, patients with psychogenic polydipsia, and patients treated with medications that increase the risk of hyponatremia; see Drug/Lab Interactions. Acute hyponatremia can lead to acute hyponatremic encephalopathy. Avoid potassium chloride injection in patients with or at risk for hyponatremia. If use cannot be avoided, monitor serum sodium concentrations. ■ Solutions containing dextrose should be used with caution in patients with diabetes mellitus. ■ Use potassium acetate with caution; excess administration may result in metabolic alkalosis. ■ Use potassium acetate with caution in patients with metabolic or respiratory alkalosis and in patients with severe hepatic insufficiency. ■ Administration of IV solutions can cause fluid and/or solute overload, resulting in dilution of serum electrolyte concentrations, overhydration, congested states, or pulmonary edema. The risk of dilutional states is inversely proportional to the electrolyte concentration. The risk of solute overload causing congested states with peripheral and pulmonary edema is directly proportional to the electrolyte concentration. ■ Some solutions of potassium may contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation.

Monitor:

Patients requiring highly concentrated solutions should be kept on continuous cardiac monitoring and undergo frequent testing for serum potassium and acid-base balance. ■ Potassium replacement should be guided primarily by ECG monitoring and secondarily by serum potassium levels, especially in patients taking digoxin. Serum potassium levels are not necessarily dependable indicators of tissue potassium levels. ■ Continuous cardiac monitoring is preferable for infusions of over 10 mEq of potassium in 1 hour. ■ Monitor changes in fluid balance, electrolyte concentration, and acid-base balance (e.g., serum potassium, sodium, chloride, bicarbonate, urinary output, pH). Only extracellular potassium can be measured; intracellular potassium equals 98% of total body potassium. Entire clinical picture must be considered. ■ Confirm absolute patency of vein. Extravasation will cause severe tissue or nerve damage. Local pain and phlebitis may occur with concentrations greater than 40 mEq/L. ■ See Drug/Lab Interactions.

Patient Education:

Report burning or stinging at IV site promptly.

Maternal/Child:

Effect unknown; use caution and only if clearly needed in pregnancy and breast-feeding. ■ Safety and effectiveness for use of KCl in pediatric patients not established. However, use for treatment of potassium deficiency when oral therapy is not feasible is referenced in medical literature. Safety and effectiveness of potassium acetate for use in pediatric patients have been established.

Elderly:

See Dose Adjustments. Monitoring of renal function suggested. ■ Increased risk of hyperkalemia.

DRUG/LAB INTERACTIONS

Risk of hyperkalemia may be increased with concurrent administration of **angiotensin-converting enzyme inhibitors, angiotensin receptor blockers,**

tacrolimus, and **cyclosporine.** ■ Concurrent administration with **potassium-sparing diuretics** may cause hyperkalemia. ■ Concurrent use with **medications associated with hyponatremia** (e.g., certain diuretics, antiepileptic and psychotropic medications) may increase the risk of hyponatremia. If concomitant use cannot be avoided, monitor serum sodium levels carefully.

SIDE EFFECTS

Abdominal pain, diarrhea, nausea, and vomiting are common side effects of potassium administration and may progress to potassium intoxication. Asystole,[a] bradycardia, cardiac arrest,[a] chest pain, dyspnea, extravasation, fever, hyperkalemia, hypersensitivity (manifested by rash and angioedema), hypervolemia, hyponatremia, hyponatremic encephalopathy, infection or pain at the site of injection, phlebitis, venous thrombosis, or ventricular fibrillation[a] may occur.

Potassium intoxication:

Areflexia (absence of reflexes), cardiac arrest, cardiac arrhythmias (e.g., asystole, bradycardia, heart block, ventricular tachycardia or fibrillation), ECG abnormalities (including increased amplitude of T wave, disappearing P wave, QRS widening), hypotension, mental confusion, muscle weakness up to and including muscular and respiratory paralysis, paresthesias of the extremities, weakness. Progression of side effects may cause death.

Potassium deficit:

Disruption of neuromuscular function, intestinal ileus, and dilatation.

ANTIDOTE

For any side effect, notify the physician. In the event of hyperkalemia, discontinue the infusion immediately and eliminate potassium-containing foods and medicines. Institute close ECG, laboratory, and other monitoring and, as necessary, corrective therapy to reduce serum potassium levels. For severe hyperkalemia (over 6.5 mEq/L plasma), insulin and dextrose may be administered to shift potassium into cells. Several regimens are described in the literature. One regimen recommends a bolus injection of 10 units of regular insulin followed by 50 mL of 50% dextrose. One manufacturer recommends IV dextrose, 10% to 25%, containing 10 units of regular insulin per 20 Gm of dextrose infused at 300 to 500 mL per hour. If P waves are absent, give calcium gluconate or chloride 0.5 to 1 Gm over 2 to 3 minutes (exceeds usual rate of administration). Do not use calcium, or use with extreme caution, if patient is receiving digoxin. All of these measures cause a shift of potassium into the cells and may be used simultaneously. Sodium polystyrene sulfonate (Kayexalate) orally or as retention enemas is used to actually remove potassium from the body. Hemodialysis or peritoneal dialysis may be useful. Use caution in the digitalized patient; too-rapid removal of potassium may cause digoxin toxicity. Resuscitate as necessary. For extravasation, apply warm, moist compresses.

PRALATREXATE

(pral-a-**TREX**-ate)
Folotyn
Antineoplastic (Antifolate)
pH 7.5 to 8.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Vitamin supplementation required. 10 days before starting pralatrexate, begin folic acid 1 to 1.25 mg PO daily. Continue daily throughout the full course of therapy and for 30 days after the last dose of pralatrexate. Administer vitamin B_{12} (1 mg) IM within the 10 weeks before starting pralatrexate and every 8 to 10 weeks thereafter. Subsequent vitamin B_{12} injections may be given the same day as pralatrexate. Baseline studies indicated; see Monitor.

Pralatrexate:

30 mg/M^2 by IV push over 3 to 5 minutes via the side port of a free-flowing infusion of NS. Administer once weekly for 6 weeks in 7-week cycles until progressive disease or unacceptable toxicity occurs. Management of severe or intolerable side effects may require dose omission or reduction or interruption of therapy; see Dose Adjustments.

DOSE ADJUSTMENTS

Decrease initial dose to 15 mg/M^2 for patients with severe renal impairment (estimated glomerular filtration rate [eGFR] 15 to <30 mL/min/1.73 M^2). ■ Before administering any dose of pralatrexate, mucositis should be equal to or less than Grade 1, platelet count should be equal to or more than 100,000 cells/mm^3 for the first dose and equal to or greater than 50,000 cells/mm^3 for all subsequent doses, and the absolute neutrophil count (ANC) should be equal to or greater than 1,000 cells/mm^3. ■ Doses may be omitted or reduced based on patient tolerance. Do not make up omitted doses at the end of the cycle, and do not re-escalate once a dose reduction occurs for toxicity. See the following three charts for dose modifications based on patient symptoms.

Guidelines for Pralatrexate Dose Modifications for Mucositis

Mucositis Grade[a] on Day of Treatment	Action	Dose Upon Recovery to ≤ Grade 1	Dose Upon Recovery in Patients With Severe Renal Impairment
Grade 2	Omit dose	Continue prior dose	Continue prior dose
Grade 2 recurrence	Omit dose	20 mg/M^2	10 mg/M^2
Grade 3	Omit dose	20 mg/M^2	10 mg/M^2
Grade 4	Stop therapy		

[a] Per National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE), Version 4.0.

Guidelines for Pralatrexate Dose Modifications for Hematologic Toxicities

Blood Count on Day of Treatment	Duration of Toxicity	Action	Dose on Restart	Dose Upon Recovery in Patients With Severe Renal Impairment
Platelets <50,000/mm^3	1 week	Omit dose	Continue prior dose	Continue prior dose
	2 weeks	Omit dose	20 mg/M^2	10 mg/M^2
	3 weeks	Stop therapy		
ANC 500 to 1,000/mm^3 and no fever	1 week	Omit dose	Continue prior dose	Continue prior dose
ANC 500 to 1,000/mm^3 with fever or ANC <500/mm^3	1 week	Omit dose, give G-CSF or GM-CSF support	Continue prior dose with G-CSF or GM-CSF support	Continue prior dose with G-CSF or GM-CSF support
	2 weeks or recurrence	Omit dose, give G-CSF or GM-CSF support	20 mg/M^2 with G-CSF or GM-CSF support	10 mg/M^2 with G-CSF or GM-CSF support
	3 weeks or 2nd recurrence	Stop therapy		

G-CSF, Granulocyte colony-stimulating factor; *GM-CSF,* granulocyte macrophage colony-stimulating factor.

Guidelines for Pralatrexate Dose Modifications for All Other Treatment-Related Toxicities

Toxicity Grade[a] on Day of Treatment	Action	Dose Upon Recovery to ≤ Grade 2	Dose Upon Recovery in Patients With Severe Renal Impairment
Grade 3	Omit dose	20 mg/M²	10 mg/M²
Grade 4	Stop therapy		

[a] Per National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE), Version 4.0.

DILUTION

Specific techniques for handling required; see Precautions.

A clear yellow solution. ***Do Not Dilute.*** Aseptically withdraw the calculated dose directly into a syringe for immediate use. Available in single-dose vials containing 20 mg/mL or 40 mg/2 mL.

Filters:

Specific information not available.

Storage:

Refrigerate vials at 2° to 8° C (36° to 46° F) in original carton to protect from light until use. Unopened vial(s) are stable in original carton at RT for up to 72 hours. Discard if left at RT for more than 72 hours. Discard any unused portion of vial.

COMPATIBILITY

Manufacturer recommends administration via the side port of a free-flowing infusion of NS.

RATE OF ADMINISTRATION

A single dose by IV push over 3 to 5 minutes via the side port of a free-flowing infusion of NS.

ACTIONS

A folate analog metabolic inhibitor. It interferes with the growth of and leads to the destruction of cancer cells by inhibiting DNA, RNA, and protein synthesis. It competitively inhibits dihydrofolate reductase and folylpolyglutamyl synthetase. This inhibition results in the depletion of thymidine and other biologic molecules. May also affect healthy cells. Approximately 67% bound to plasma proteins. Half-life is 12 to 18 hours. Excreted as unchanged in urine (approximately 39%) and as unchanged drug and metabolites in feces.

INDICATIONS AND USES

Treatment of patients with relapsed or refractory peripheral T-cell lymphoma (PTCL). This indication is based on overall response rate. Clinical benefit such as improvement in progression-free survival or overall survival has not been demonstrated.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents; see Appendix A, p. 1308. ■ Administered under the direction of a physician knowledgeable in its use and in a facility with adequate diagnostic and treatment facilities to monitor the patients and respond to any medical emergency. ■ Bone marrow suppression can occur (e.g., anemia, neutropenia, and thrombocytopenia). Dose modification based on ANC and platelet count is required before each dose; see Dose Adjustments. ■ May cause mucositis; see Dose Adjustments. ■ To potentially reduce treatment-related hematologic toxicity and mucositis, folic acid and vitamin B_{12} supplementation is required. ■ Severe dermatologic reactions, including skin exfoliation, toxic epidermal necrolysis, and ulceration, have been reported. May increase in severity with continued treatment, may involve skin and subcutaneous sites of known lymphoma, and may result in death. ■ Tumor lysis syndrome has been reported. ■ Serious adverse drug reactions, including toxic epidermal necrolysis and mucositis, were reported in patients with ESRD undergoing dialysis. ■ Avoid pralatrexate use in patients with ESRD, including those undergoing dialysis, unless the potential benefit justifies the potential risk. ■ Can cause hepatic toxicity and liver function abnormalities. Persistent liver function test abnormalities may be indicators of liver toxicity. ■ Has not been studied in patients with hepatic impairment, and patients with selected liver test elevations were excluded from clinical trials.

Monitor:

Obtain baseline CBC and platelets and serum chemistry tests, including renal and hepatic function. ■ Monitor CBC and platelets and severity of mucositis weekly before each dose. ■ Repeat serum chemistry tests, including renal and hepatic function, before the start of the first and fourth dose of a given cycle. ■ Monitor patients with moderate to severe renal function closely. Adjust dose accordingly; see Dose Adjustments. ■ Monitor patients with elevated liver enzymes closely (e.g., AST, ALT, transaminases). If liver function test abnormalities are greater than or equal to Grade 3, omit or modify dose; see Dose Adjustments. ■ Observe for S/S of skin reactions (e.g., blisters, peeling and loss of skin, rash, sores); see Antidote. ■ Monitor closely for S/S of tumor lysis syndrome (e.g., flank pain, hematuria, hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure) and treat as appropriate. Allopurinol and hydration may be indicated for prevention and/or treatment of hyperuricemia. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Use prophylactic antiemetics to reduce nausea and/or vomiting and increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient.

Patient Education:

A patient information guide is available from the manufacturer. ■ Avoid pregnancy; effective birth control is recommended. ■ Blood counts will be required at regular intervals. ■ Take folic acid and vitamin B_{12} as prescribed to help reduce side effects. ■ Report soreness in the mouth, redness of mucous membranes, difficulty swallowing, or ulcerations in the mouth. Discuss ways to avoid and/or manage mucositis with a health care professional. ■ Promptly report S/S of infection (e.g., fever), S/S of bleeding (e.g., anemia, bruising), and S/S of tumor lysis syndrome (e.g., flank pain, hematuria). ■ Promptly report S/S of skin reactions (e.g., blisters, peeling and loss of skin, rash, sores). ■ Discuss medications (prescription and nonprescription) with a health care professional; see Drug/Lab Interactions. ■ Avoid vaccination with live virus vaccines. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: avoid pregnancy. Can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in effectiveness or safety based on age. ■ No dose adjustment required in elderly patients with normal renal function; however, dose selection should be cautious. Consider age-related organ impairment (e.g., bone marrow reserve, renal, hepatic) and monitor closely.

DRUG/LAB INTERACTIONS

Coadministration with **probenecid** (an inhibitor of multiple transporter systems, including the multidrug resistance–associated protein 2 [MRP2] efflux transporter) resulted in delayed renal clearance and an increase in pralatrexate exposure. ■ Concomitant administration of drugs that are substantially cleared by the renal system (e.g., **NSAIDs and sulfamethoxazole/trimethoprim**) may result in delayed clearance of pralatrexate. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Not a substrate, inhibitor, or inducer of CYP_{450} isoenzymes and has a low potential for drug-drug interactions with drugs metabolized by these isoenzymes.

SIDE EFFECTS

The most common side effects are fatigue, mucositis, nausea, and thrombocytopenia. The most common serious side effects are dehydration, dyspnea, febrile neutropenia, fever, mucositis (stomatitis or mucosal inflammation of the GI and GU tracts), sepsis, and thrombocytopenia. Mucositis and thrombocytopenia were the most common reasons for discontinuing treatment. Other reported side effects include abdominal pain, abnormal liver function tests (e.g., AST, ALT, transaminases), anemia, anorexia, asthenia, back pain, constipation, cough, diarrhea, edema, epistaxis, hypokalemia, leukopenia, neutropenia, night sweats, pain in extremities, pharyngolaryngeal pain, pruritus, rash, tachycardia, tumor lysis syndrome, upper respiratory infection, vomiting.

Post-Marketing:

Dermatologic reactions (e.g., skin exfoliation, toxic epidermal necrolysis, and ulceration).

ANTIDOTE

Treatment of most side effects will be supportive and may require dose adjustment or discontinuation. Discontinue pralatrexate if toxicity from side effects occurs (e.g., dermatologic reactions, Grade 4 treatment-related toxicities [e.g., mucositis], hematologic toxicities [persisting for 3 weeks], uncontrolled tumor lysis syndrome) and notify the physician; see Dose Adjustments. Administration of blood products and/or blood modifiers (e.g., darbepoetin, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Treat hypersensitivity reactions with epinephrine, antihistamines, and corticosteroids as needed. In addition to initiating supportive measures, leucovorin calcium (citrovorum factor, folinic acid) may be given PO, IM, or IV promptly to counteract inadvertent overdose. Resuscitate as indicated.

PRALIDOXIME CHLORIDE

(prah-lih-**DOX**-eem **KLOR**-eyed)
Protopam Chloride
Antidote (anticholinesterase antagonist)
pH 3.5 to 4.5

USUAL DOSE

Pretreatment:

In poisonings, correct any existing hypoxemia and obtain baseline studies; see Monitor.

Administer atropine as directed in the following paragraphs. After the effects of atropine have become apparent, pralidoxime may be administered. See Contraindications. If IV administration is not possible, may be given IM or SC.

Organophosphate Pesticide Poisoning

Atropine:

Must be given before pralidoxime and as soon as possible after adequate ventilation has been established (hypoxemia corrected). Ventricular fibrillation can occur if oxygenation is inadequate. Give atropine, 2 to 4 mg IV, after cyanosis disappears, then give initial dose of pralidoxime. Repeat atropine every 10 minutes until atropine toxicity (delirium, dilated pupils, dry mouth, muscle twitching, pulse 140 beats/min). Maintain atropinization for at least 48 hours.

Pralidoxime:

1 to 2 Gm initially after hypoxemia has been corrected, initial dose of atropine has been given, and effects of atropine are apparent (secretions are inhibited). Repeat in 1 hour if indicated. If muscle weakness continues, additional doses can be given with extreme caution, usually every 10 to 12 hours (has been given more frequently). Evidence suggests that a loading dose followed by a continuous infusion may maintain therapeutic levels longer than the traditional short intermittent infusion therapy; see prescribing information for studied regimens.

Organophosphate Chemical Poisoning

Usually administered IM by an autoinjector system (survival technology). Atropine must be given first. After the effects of atropine are apparent (e.g., dry mouth), give pralidoxime 600 mg. Repeat both drugs at 15-minute intervals times 2 if indicated. If muscle weakness persists, seek medical help; IV doses may be required.

Anticholinesterase Overdose (e.g., Neostigmine, Pyridostigmine)

1 to 2 Gm followed by 250 mg every 5 minutes.

PEDIATRIC DOSE

See Maternal/Child.

Organophosphate pesticide/chemical poisoning:

Give **atropine** 0.05 to 0.1 mg/kg. See Usual Dose for order of administration and specific criteria.

Pralidoxime—Loading dose followed by a continuous infusion:

Administer a loading dose of 20 to 50 mg/kg (not to exceed 2,000 mg) over 15 to 30 minutes. Follow with a continuous infusion of 10 to 20 mg/kg/hr.

Pralidoxime—Intermittent Infusion:

Administer 20 to 50 mg/kg (not to exceed 2,000 mg) over 15 to 30 minutes. May repeat dose in 1 hour if muscle weakness has not been relieved. Repeat every 10 to 12 hours as needed.

DOSE ADJUSTMENTS

Reduce dose in renal impairment. ■ Lower-end initial doses may be indicated in the elderly. Dose selection should be cautious in the elderly. Consider age-related organ impairment and concomitant disease or drug therapy.

DILUTION

Each 1 Gm of sterile powder is diluted with 20 mL of SWFI. Should be further diluted in 100 mL of NS and given as an IV infusion. If reduced fluids are indicated (e.g., pulmonary edema is present) or rapid administration is required, a 5% solution (1 Gm in 20 mL SWFI) given over no less than 5 minutes may be used.

Storage:

Store at CRT. Use promptly after reconstitution; discard remaining solution.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Too-rapid injection may cause laryngospasm, muscle rigidity, or tachycardia. Do not exceed a rate of 200 mg/min.

IV injection diluted in 20 mL SWFI:

Each 1 Gm or fraction thereof over no less than 5 minutes. Used only if pulmonary edema present or infusion not practical.

Infusion (diluted in 100 mL NS, preferred):

A single dose over 15 to 30 minutes.

ACTIONS

An anticholinesterase antagonist that reactivates cholinesterase inhibited by phosphate esters. Slows the conversion of phosphorylated cholinesterase to a nonreactivatable form and detoxifies certain organophosphates by direct chemical reaction. Its most critical effect is in relieving paralysis of the respiratory muscles. Because pralidoxime is less effective in relieving depression of the respiratory center, atropine is always required concomitantly to block the effect of accumulated acetylcholine at this site. Rapidly dispersed throughout body fluids. Onset of action is within 10 to 40 minutes; half-life is short (about 1.2 hours), requiring repeated doses as more poison is absorbed. Partially metabolized by the liver. Most of a single dose is excreted within 6 hours in the urine.

INDICATIONS AND USES

Principal indications for the use of pralidoxime are muscle weakness and respiratory depression. In severe poisoning, respiratory depression may be due to muscle weakness. ■ An antidote (treatment adjunct) in organophosphate pesticide or chemical poisoning. Primarily useful for many phosphate ester insecticide poisons with anticholinesterase activity (e.g., diazinon, malathion) or chemicals with anticholinesterase activity (e.g., nerve gas). ■ Control of overdose of anticholinesterase drugs used to treat myasthenia gravis. Confirm diagnosis with edrophonium (Tensilon).

CONTRAINDICATIONS

No known absolute contraindications to use of pralidoxime. Relative contraindications include known hypersensitivity to pralidoxime or any component of the product. ■ See Precautions.

PRECAUTIONS

In poisoning:

Most effective if administered immediately after poisoning. May be ineffective if more than 36 hours have passed since exposure; some response may be obtained in severe poisoning; see Contraindications. ■ Not recommended in carbamate poisoning (increases toxicity of Sevin [carbamate insecticide]). ■ Not effective for treatment of poisoning with phosphorus, inorganic phosphates, or organophosphates not having anticholinesterase activity. ■ Rapid IV administration may lead to temporary worsening of cholinergic manifestations. Continuous or intermittent infusion is preferred; see Rate of Administration. ■ Caregivers must protect themselves from contamination. Wear gowns and gloves. ■ Remove contaminated clothing and cleanse contaminated skin surfaces, hair, and fingernails with water, sodium bicarbonate solution, or alcohol. ■ Gently flush eyes with water for at least 15 minutes. ■ Diazepam (Valium) may be required to stop convulsions. ■ Use caution in myasthenia gravis; may cause a myasthenic crisis.

Monitor:

Before any medication is given, establish and maintain an adequate airway and controlled respiration as indicated. Suctioning of secretions and oxygen usually required. Cardiovascular support, correction of metabolic abnormalities, and seizure control may be necessary. ■ Draw blood samples for baseline RBC acetylcholinesterase and pseudocholinesterase concentrations. ■ In suspected poisoning, initiate treatment without waiting for lab confirmation of diagnosis. Combined with a history of possible poisoning, a RBC cholinesterase concentration less than 50% of normal is indicative of organophosphate ester poisoning. ■ Gastric lavage and activated charcoal are indicated if organophosphates are ingested; most effective if started within 30 minutes of ingestion. Avoid emesis as patient may lose consciousness and aspirate. ■ Monitor vital signs and ECG continuously. ■ Maintain adequate urine output. ■ In cases of ingested poison, toxicity may recur as poison is absorbed from bowel; monitor for 48 to 72 hours. ■ In all cases of organophosphate poisoning, patient should be observed for at least 48 to 72 hours. ■ See Drug/Lab Interactions.

Maternal/Child:

Category C: effects not known; use only if clearly needed. ■ Safety for breast-feeding not established. ■ Efficacy in pediatric patients is extrapolated from the adult population and is supported by nonclinical studies, pharmacokinetic studies in adults, and experience in pediatric patients. Muscle fasciculations, apnea, and convulsions have been reported; see Rate of Administration.

Elderly:

Response similar to younger adults. ■ Dose selection should be cautious; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Used in combination with **atropine.** Signs of atropinization (e.g., dryness of mouth and nose, flushing, mydriasis, tachycardia) may occur earlier than when atropine is used alone. ■ **CNS depressants** (e.g., anticonvulsants, antihistamines, muscle relaxants, narcotics, reserpine compounds, phenothiazines) and xanthines (e.g., aminophylline, caffeine) will intensify the effects of organophosphate poisoning and defeat effectiveness of treatment. ■ **Barbiturates** are potentiated by anticholinesterases; use with caution in treatment of seizures. ■ **Succinylcholine** may cause prolonged respiratory paralysis. ■ **Thiamine** delays excretion of pralidoxime.

SIDE EFFECTS

Blurred vision, diplopia, dizziness, drowsiness, headache, hyperventilation, impaired accommodation, increased diastolic and systolic BP, laryngospasm, muscle rigidity, muscular weakness, nausea, pharyngeal pain, tachycardia, transient elevated AST, ALT, and CPK. Excitement and manic behavior may occur (atropinization) if pralidoxime is delayed after atropine has been given.

ANTIDOTE

Has not been needed. Patient should be observed for atropine intoxication. Artificial ventilation and other supportive therapy should be administered as needed.

PROCAINAMIDE HYDROCHLORIDE

(proh-**KAYN**-ah-myd hy-droh-**KLOR**-eyed)
Antiarrhythmic
pH 4 to 6

USUAL DOSE

Loading dose:

0.2 to 1 Gm (100 mg/mL). 100 mg every 5 minutes or 20 mg every 1 minute may be given as an infusion until arrhythmia is suppressed or 500 mg is administered. Wait 10 minutes to allow adequate distribution, then resume dosing until arrhythmia is suppressed, maximum initial dose of 1 Gm is reached, or side effects appear (e.g., hypotension, QRS complex widening by 50%). Dose cautiously to avoid a hypotensive response. AHA recommends 20 mg/min as an infusion to a maximum total dose of 17 mg/kg. ***Maintenance dose:*** After arrhythmia is suppressed or maximum dose is reached, follow initial dose with an infusion of 1 to 4 mg/min (may require up to 6 mg/min). Titrate to control arrhythmias. Maintain with oral procainamide as soon as possible but at least 4 hours after last IV dose.

Recurrent VT/VF:

AHA recommends 20 mg/min as an infusion. Up to 50 mg/min may be used in urgent situations. Maximum total dose is 17 mg/kg.

PEDIATRIC DOSE

See Maternal/Child; pediatric doses are unlabeled.

2 to 5 mg/kg of body weight. Do not exceed 100 mg/dose. Repeat as indicated every 10 to 30 minutes. Maximum dose in 24 hours is 30 mg/kg or 2 Gm. An alternate dose

regimen is 2 to 6 mg/kg as a ***loading dose*** given over 5 minutes; follow with a ***maintenance infusion*** of 20 to 80 mcg/kg/min to control arrhythmias.

Supraventricular tachycardia (SVT), atrial flutter, VT with pulse:

AHA recommends 15 mg/kg over 30 to 60 minutes.

DOSE ADJUSTMENTS

Maintenance dose may be reduced in impaired or reduced renal function and in individuals over 50 years of age. ■ See Drug/Lab Interactions.

DILUTION

IV injection:

Dilute each 100 mg with 5 to 10 mL of D5W.

Infusion:

Add 1 Gm of procainamide to 50, 250, or 500 mL of D5W. Yields 20 mg/mL, 4 mg/mL, or 2 mg/mL, respectively. 20 mg/mL should be used only as a loading dose. 2 and 4 mg/mL dilutions may be used for loading or maintenance based on fluid restrictions. Solution should be clear; may be light yellow. Discard if darker than light amber.

Pediatric infusion:

Loading dose:

Add a calculated loading dose (2 to 5 mg/kg) to a minimum of 10 mL D5W for each 100 mg or fraction thereof. More diluent may be used based on size of child and fluid restriction.

Maintenance infusion:

See chart under Rate of Administration (Pediatric).

Storage:

Photosensitive; protect from light. Store at CRT.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

20 mg or fraction thereof over 1 minute. Use an infusion pump or a microdrip (60 gtt/mL) for infusion to deliver a constant rate. Up to 50 mg may be given by IV injection over 1 minute with extreme caution. After stabilized with loading dose, follow with a maintenance infusion at 1 to 6 mg/min.

Procainamide Infusion Rate (Adult)

Desired Dose	1 Gm in 500 mL D5W 2 mg/mL			1 Gm in 250 mL D5W 4 mg/mL		
mg/min	**mg/hr**	**mL/min**	**mL/hr**	**mg/hr**	**mL/min**	**mL/hr**
1 mg/min	60	0.5	30	60	0.25	15
2 mg/min	120	1	60	120	0.5	30
3 mg/min	180	1.5	90	180	0.75	45
4 mg/min	240	2	120	240	1	60
5 mg/min	300	2.5	150	300	1.25	75
6 mg/min	360	3	180	360	1.5	90

Procainamide Infusion Rate (Pediatric)

Desired Dose	200 mg in 500 mL D5W 400 mcg/mL	200 mg in 125 mL D5W 1,600 mcg/mL
mcg/kg/min	**mL/kg/min × kg = mL/min**	**mL/kg/min × kg = mL/min**
20 mcg/kg/min	0.05 × wt in kg	0.0125 × wt in kg
30 mcg/kg/min	0.075 × wt in kg	0.01875 × wt in kg
40 mcg/kg/min	0.1 × wt in kg	0.025 × wt in kg
50 mcg/kg/min	0.125 × wt in kg	0.03125 × wt in kg
60 mcg/kg/min	0.15 × wt in kg	0.0375 × wt in kg
70 mcg/kg/min	0.175 × wt in kg	0.04375 × wt in kg
80 mcg/kg/min	0.2 × wt in kg	0.05 × wt in kg

Example: To deliver 30 mcg/kg/min of a 400 mg/mL solution to a child weighing 20 kg, multiply 0.075 (mL/kg/min) × 20 (wt in kg) = an infusion rate of 1.5 mL/min.

ACTIONS

A procaine derivative. Exerts a depressing antiarrhythmic action on the heart, slowing the rate, slowing conduction, reducing myocardial irritability, and prolonging the refractory period. Decreases membrane permeability of the cell and prevents loss of sodium and potassium ions. Onset of action should occur in 2 to 3 minutes. Half-life is 3 to 4 hours. Crosses the placental barrier. Plasma levels decrease slowly; partially metabolized to the active metabolite NAPA; remaining drug excreted in the urine.

INDICATIONS AND USES

Suppress PVCs and recurrent ventricular tachycardia when lidocaine is contraindicated or has not suppressed ventricular arrhythmias. ■ Treat wide-complex tachycardias difficult to distinguish from VT (lidocaine preferred). ■ Rarely used in atrial fibrillation, paroxysmal atrial tachycardia, or arrhythmias caused by anesthesia. Safer drugs (e.g., verapamil, diltiazem) are readily available.

CONTRAINDICATIONS

Complete atrioventricular heart block, second- and third-degree AV block unless an electrical pacemaker is operative, pre-existing QT prolongation, torsades de pointes, known sensitivity to procainamide or any other local anesthetic of the ester type, myasthenia gravis, systemic lupus erythematosus.

PRECAUTIONS

Oral or IM administration is the route of choice; IV route for emergencies only. ■ Use extreme caution in first- or second-degree blocks, ventricular tachycardia after a myocardial infarction, digoxin intoxication, CHF, any structural heart disease, and impaired liver or reduced kidney function. ■ Predigitalize or cardiovert patients with atrial flutter or fibrillation to reduce incidence of sudden increase in ventricular rate as atrial rate is slowed. Use caution if used concurrently with other drugs that prolong QT interval (e.g., amiodarone). ■ Some clinicians recommend giving a dose the night before surgery and then discontinuing until after surgery. If an arrhythmia occurs, use lidocaine for ventricular arrhythmias and calcium channel blockers (e.g., diltiazem, verapamil) or beta-blockers (e.g., atenolol, propranolol) for supraventricular arrhythmias. Resume dosing after surgery and utilize oral dosing as soon as possible.

Monitor:

Monitor the patient's ECG and BP continuously. Keep patient in a supine position. Avoid a hypotensive response. ■ Discontinue IV use when the cardiac arrhythmia is interrupted or when the ventricular rate slows without regular atrioventricular conduction. ■ Small emboli may be dislodged when atrial fibrillation is corrected. ■ Monitor blood levels of procainamide and NAPA (active metabolite) in patients with renal impairment and in any patient receiving a constant infusion over 3 mg/min for more than 24 hours. ■ Monitor CBC, including WBC, differential, and platelets, with continued use; fatal blood dyscrasias have occurred with usual doses. ■ See Drug/Lab Interactions.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding and in pediatric patients not established. Consider quinidine as an alternate for use during pregnancy.

Elderly:

Half-life of parent drug and active metabolite is prolonged; renal excretion reduced about 25% at age 50 and 50% at age 75. ■ Increased risk of hypotension.

DRUG/LAB INTERACTIONS

Potentiates or is potentiated by **neuromuscular blocking antibiotics** (e.g., kanamycin), **anticholinergics** (e.g., atropine), **thiazide diuretics, antihypertensive agents, muscle relaxants, succinylcholine, cimetidine, and others**. ■ May cause serious arrhythmias (e.g., prolongation of QT interval or other additive effects) with **other antiarrhythmic agents** (e.g., amiodarone, digoxin, disopyramide, lidocaine, quinidine). Lower doses of both drugs may be required. ■ Antagonizes **anticholinesterases** (e.g., neostigmine). ■ **Alcohol** may increase hepatic metabolism. ■ May **elevate AST levels.**

SIDE EFFECTS

Anorexia, bleeding, bruising, chills, dizziness, fever, flushing, giddiness, hallucinations, joint swelling or pain, mental confusion, nausea, skin rash, tremor, vomiting, weakness. May indicate onset of more serious side effects.

Major:

Blood dyscrasias (e.g., agranulocytosis, bone marrow suppression, hypoplastic anemia, neutropenia, thrombocytopenia), hypotension with a BP drop over 15 mm Hg, lupus erythematosus-like symptoms, PR interval prolongation, QRS complex widening, QT interval prolongation, ventricular asystole, ventricular fibrillation, ventricular tachycardia.

ANTIDOTE

Notify the physician of any side effect. If minor symptoms progress or any major side effect appears, discontinue the drug immediately and notify the physician. Use dopamine or phenylephrine hydrochloride to correct hypotension. Treatment of toxicity is symptomatic and supportive. Infusion of ⅙ M sodium lactate injection may reduce cardiotoxic effects. Hemodialysis may be indicated or urinary acidifiers may increase renal clearance. Resuscitate as necessary. Depending on arrhythmia, quinidine or lidocaine is an effective alternate. Consider insertion of a ventricular pacing electrode as a precautionary measure in case serious AV block develops.

PROCHLORPERAZINE EDISYLATE

(proh-klor-**PAIR**-ah-zeen eh-**DIS**-ah-layt)
Compazine
Phenothiazine
Antiemetic
Antipsychotic
pH 4.2 to 6.2

USUAL DOSE

A single IV dose should not exceed 10 mg. The maximum daily IV dose should not exceed 40 mg.

Control of severe nausea and vomiting:

2.5 to 10 mg; may be repeated one time in 1 to 2 hours if indicated.

Control of severe nausea and vomiting in adult surgical patients:

5 to 10 mg 15 to 30 minutes before induction of anesthesia or to control symptoms during or after surgery. Repeat once if necessary. Another source suggests 20 mg diluted in 1 L solution (see Dilution) during and/or after surgery.

Management of nausea and vomiting in emetic-inducing chemotherapy (unlabeled):

One source suggests 10 to 20 mg 30 minutes before and 3 hours after treatment. Another source suggests 30 to 40 mg 30 minutes before and 3 hours after treatment. A third source suggests 0.8 mg/kg 30 minutes before and 3 hours after treatment and cites precipitous hypotension with larger doses; but another source suggests 2 mg/kg for highly emetogenic agents (e.g., cisplatin, dacarbazine) and 1 mg/kg for less emetogenic agents. Begin 30 minutes before chemotherapy, repeat every 2 hours for 2 doses, then every 3 hours for 3 doses. Treat extrapyramidal symptoms with diphenhydramine IM. These doses have not been recommended by the manufacturer and exceed the recommended maximum daily IV dose of 40 mg/24 hr.

Control of severe vascular and tension headaches (unlabeled):

10 mg given as an injection over 2 minutes. Sometimes given concurrently with dihydroergotamine 1 mg as an infusion over 30 minutes. Another regimen administers 3.5 mg of prochlorperazine over 5 minutes followed by dexamethasone 20 mg over 10 minutes.

PEDIATRIC DOSE

IV route not recommended for pediatric patients; safety has not been established; see Contraindications, Precautions, and Maternal/Child.

DOSE ADJUSTMENTS

Lower-end initial doses and more gradual adjustments may be indicated in the elderly and in debilitated or emaciated patients. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted or each 5 mg (1 mL) may be diluted with 9 mL of NS to facilitate titration. 1 mL will equal 0.5 mg. Larger amounts of NS may be used. May add doses over 10 mg to 50 mL to 1 liter of commonly used IV solution (e.g., D5W, NS, D5/½NS, Ringer’s or LR), and give as an intermittent or prolonged infusion. Handle carefully; may cause contact dermatitis. Slightly yellow color does not affect potency. Discard if markedly discolored.

Storage:

Store below 40° C and protect from light and freezing.

COMPATIBILITY

Manufacturer recommends not mixing with other agents in a syringe.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Each 5 mg or fraction thereof over 1 minute.

Infusion:

May be given at ordered rate, or rate may be increased or decreased as symptoms indicate. Use an infusion pump for infusion.

Management of nausea and vomiting associated with emetic-inducing chemotherapy:

A single dose over 15 to 20 minutes as an ***intermittent IV.***

ACTIONS

A phenothiazine derivative approximately six times more potent than chlorpromazine, with effects on the central, autonomic, and peripheral nervous systems. Has weak anticholinergic effects, moderate sedative effects, and strong extrapyramidal effects. A potent antiemetic, acting both centrally at the chemoreceptor trigger zone and peripherally by blocking the vagus nerve in the GI tract. Onset of action is prompt and lasting. Metabolized in the liver and excreted in urine and feces. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Control of severe nausea and vomiting. ■ Used IM or PO in the treatment of schizophrenia and nonpsychotic anxiety.

Unlabeled uses:

Use of higher doses to control nausea and vomiting associated with emetic-inducing chemotherapy. ■ Treatment of severe vascular and tension headaches.

CONTRAINDICATIONS

Pediatric patients under 2 years or 10 kg (22 lb); pediatric patients with conditions that do not have an established dose; comatose or severely depressed states or in the presence of large amounts of CNS depressants (e.g., alcohol, barbiturates, narcotics); hypersensitivity to phenothiazines; breast-feeding and pregnancy, except labor and delivery; do not use in pediatric surgery.

PRECAUTIONS

Use IV only when absolutely necessary. IV not recommended for pediatric patients. ■ Extrapyramidal symptoms caused by prochlorperazine may be confused with undiagnosed disease (e.g., Reye’s syndrome, encephalopathy). ■ May mask diagnosis of other conditions, including Reye’s syndrome, brain tumor, drug intoxication, and intestinal obstruction. ■ May produce ECG changes (e.g., prolonged QT interval, changes in T waves). ■ Use caution in coronary disease, glaucoma, severe hypertension or hypotension, and in patients with bone marrow suppression. ■ Use caution in patients with epilepsy. May lower the seizure threshold. ■ Neuroleptic malignant syndrome (NMS), characterized by hyperpyrexia, muscle rigidity, autonomic instability, and altered mental status, has been reported with phenothiazine use. ■ Tardive dyskinesia (potentially irreversible involuntary dyskinetic movements) may develop.

Use the smallest doses and shortest duration of therapy to minimize risk. ■ Anticholinergic and cardiac effects may be troublesome during anesthesia. For patients receiving phenothiazines, taper and discontinue preoperatively if they will not be continued after surgery. ■ May discolor urine pink to reddish brown. ■ Photosensitivity of skin is possible. ■ May cause paradoxical excitation in pediatric patients and the elderly. ■ Do not re-expose patients who have experienced jaundice, skin reactions, or blood dyscrasias in reaction to a phenothiazine. Cross-sensitivity may occur. ■ May contain sulfites; use caution in patients with allergies.

Monitor:

Keep patient in supine position and monitor BP and pulse before administration and between doses. ■ Cough reflex may be suppressed. Monitor closely if nauseated or vomiting to prevent aspiration. ■ See Drug/Lab Interactions.

Patient Education:

Avoid use of alcohol or other CNS depressants (e.g., antihistamines, barbiturates). ■ Request assistance for ambulation; may cause dizziness or fainting. ■ Use caution performing tasks that require alertness. ■ May cause skin and eye photosensitivity. Avoid unprotected exposure to sun.

Maternal/Child:

Safety for use in pregnancy, breast-feeding, and pediatric patients not established; see Contraindications. ■ Has been used during pregnancy for intractable nausea and vomiting; physician must decide if benefit outweighs risk. ■ Use near term may cause maternal hypotension and adverse neonatal effects (e.g., extrapyramidal syndrome, hyperreflexia, hyporeflexia, jaundice). ■ Fetuses and infants have a reduced capacity to metabolize and eliminate. ■ Pediatric patients may metabolize antipsychotic agents more rapidly than adults. ■ Incidence of extrapyramidal reactions is relatively high in pediatric patients, especially in the presence of acute illness (e.g., measles, chickenpox, gastroenteritis).

Elderly:

See Dose Adjustments and Precautions. ■ Have a reduced capacity to metabolize and eliminate and may have increased sensitivity to postural hypotension, anticholinergic and sedative effects. ■ Increased risk of extrapyramidal side effects (e.g., tardive dyskinesia, parkinsonism).

DRUG/LAB INTERACTIONS

Use with **epinephrine** not recommended; may cause precipitous hypotension. ■ Increased CNS respiratory depression and hypotensive effects with **narcotics, alcohol, anesthetics, barbiturates;** reduced doses of these agents usually indicated. ■ Additive effects with **MAO inhibitors, anticholinergics, antihistamines, antihypertensives, hypnotics, muscle relaxants, phenytoin, propranolol, rauwolfia alkaloids, and thiazide diuretics;** dose adjustment may be necessary. ■ Risk of cardiotoxicity increased with **pimozide**; concurrent use not recommended. ■ Risk of additive QT interval prolongation, cardiac depressant effects, and cardiac arrhythmias increased with **amiodarone, disopyramide, erythromycin, probucol, procainamide, and quinidine**. ■ Concurrent use with **antidepressants** or **MAO inhibitors** may increase effects of both drugs; risk of neuroleptic malignant syndrome may be increased. ■ Encephalopathic syndrome has been reported with concurrent use of **lithium;** monitor for S/S of neurologic toxicity. ■ May diminish effects of **oral anticoagulants.** ■ May lower seizure threshold. Dose adjustment of **anticonvulsants** may be necessary. ■ Use with **metrizamide** may lower seizure threshold; discontinue prochlorperazine 48 hours before **myelography,** and do not resume for 24 hours after test is completed. ■ Use caution during anesthesia with **barbiturates** (e.g., methohexital, thiopental); may increase frequency and severity of hypotension and neuromuscular excitation. ■ Capable of innumerable other interactions.

SIDE EFFECTS

Usually transient if drug discontinued but may require treatment if severe: anaphylaxis, blurring of vision, cardiac arrest, dermatitis, dizziness, drowsiness, dryness of mouth, dysphagia, elevated BP, extrapyramidal symptoms (e.g., abnormal positioning, extreme restlessness, pseudoparkinsonism, weakness of extremities), excitement, fever without etiology, hematologic toxicities (e.g., agranulocytosis, aplastic anemia, leukopenia, thrombocytopenia), hypersensitivity reactions, hypotension, photosensitivity, slurred speech, spastic movements (especially about the face), tachycardia, tardive dyskinesia, tightness of the throat, tongue discoloration, tongue protrusion, and many others. Overdose can cause convulsions, hallucinations, and death.

ANTIDOTE

Discontinue the drug at onset of any side effect and notify the physician. Discontinue prochlorperazine and all drugs not essential to concurrent therapy immediately if NMS occurs. Will require intensive symptomatic treatment, medical monitoring, and management of concomitant medical problems. Counteract hypotension with IV fluids and norepinephrine or phenylephrine; counteract extrapyramidal symptoms with benztropine mesylate or diphenhydramine. Maintain a clear airway and adequate hydration. ***Epinephrine is contraindicated for hypotension.*** Further hypotension will occur. Use diazepam for convulsions or hyperactivity. Follow with phenytoin. Phenytoin may be helpful in ventricular arrhythmias. In treating respiratory depression and unconsciousness, avoid analeptics such as doxapram; they may cause convulsions. Not removed by dialysis. Resuscitate as necessary.

PROMETHAZINE HYDROCHLORIDE BBW

(proh-**METH**-ah-zeen hy-droh-**KLOR**-eyed)
Phenergan
Phenothiazine
Antiemetic
Histamine H_1 antagonist
pH 4 to 5.5

USUAL DOSE

A vesicant; see Dilution, Rate of Administration, Contraindications, Precautions, Monitor, and Antidote. Deep IM injection is the preferred route of administration.

All uses:

The Institute for Safe Medication Practices (ISMP) recommends 6.25 to 12.5 mg as a starting IV dose and limiting the concentration available to the 25 mg/mL product.

Nausea and vomiting:

12.5 to 25 mg every 4 to 6 hours as needed.

Allergic conditions:

25 mg. May repeat in 2 hours if necessary. Change to oral therapy as soon as possible.

Sedation, nighttime:

25 to 50 mg.

Sedation, perioperative:

25 to 50 mg. May combine with a reduced dose of narcotic analgesic and an anticholinergic drug (e.g., atropine).

Sedation, labor and delivery:

50 mg during early stage of labor. When labor fully established, may administer 25 to 75 mg with a reduced dose of a narcotic analgesic. May repeat every 4 hours to a maximum dose of 100 mg in a 24-hour period.

PEDIATRIC DOSE

IV use is rare and is limited to pediatric patients 2 years of age or older; see Contraindications and Maternal/Child. Adjust dose to the age, weight, and severity of condition. Use the minimum effective dose and avoid concomitant administration with other drugs with respiratory depressant effects. Do not exceed one-half of adult dose.

Adjunct to premedication:

1.1 mg/kg/dose.

DOSE ADJUSTMENTS

Reduced dose may be indicated in the elderly. See Drug/Lab Interactions.

DILUTION

Concentration should never exceed 25 mg/mL. 1 mL (25 to 50 mg) diluted with 9 mL of NS equals 2.5 to 5 mg/mL. **The ISMP recommends further dilution with an additional 10 to 20 mL of NS.** Administer through Y-tube or three-way stopcock of a free-flowing IV.

Storage:

Store at CRT. Protect from light. Do not use if solution has developed color or contains a precipitate.

COMPATIBILITY

May form a precipitate with heparin; flush heparinized infusion sets with SWFI or NS before and after administration.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

The ISMP recommends administration of a single dose over 10 to 15 minutes administered at a port farthest from the patient vein; observe continuously if given in a peripheral vein.

A maximum rate of 25 mg or fraction thereof over 1 minute is suggested by the manufacturer.

ACTIONS

A phenothiazine derivative with effects on the central, autonomic, and peripheral nervous systems. It has antihistaminic, antiemetic, anticholinergic, anti–motion-sickness, and sedative effects. Promethazine is a competitive H_1 histamine receptor antagonist but does not block the release of histamine. Clinical effects are generally apparent within 5 minutes after an IV dose. Duration of action is 4 to 6 hours, but effects may persist up to 12 hours. Half-life ranges from 9 to 16 hours. Primarily metabolized in the liver and excreted in the urine.

INDICATIONS AND USES

Amelioration of allergic reactions to blood or plasma. ■ An adjunct to the treatment of anaphylaxis after acute symptoms have been controlled with epinephrine and other standard measures. ■ Treatment of other uncomplicated hypersensitivity reactions when oral therapy is impossible or contraindicated. ■ Treatment of motion sickness. ■ Preoperative, postoperative, and obstetric (during labor) sedation. ■ Adjunct to analgesics for control of postoperative pain. ■ Sedation and relief of apprehension; production of a light sleep from which a patient can be easily aroused. ■ Prevention and control of nausea and vomiting associated with certain types of anesthesia and surgery. ■ An adjunct to anesthesia and analgesia in selected surgical situations (e.g., repeated bronchoscopy, ophthalmologic surgery, and poor-risk patients). Given in conjunction with reduced amounts of narcotic analgesics.

CONTRAINDICATIONS

Comatose or severely depressed states. ■ Hypersensitivity or an idiosyncratic reaction to phenothiazines. ■ Pediatric patients under 2 years of age. ■ Injection into an artery; may cause arteriospasm resulting in gangrene. ■ SC administration; chemical irritation may result in necrotic lesions.

PRECAUTIONS

Ampule must state “for IV use.” Deep IM injection preferred. ■ Use with extreme caution in pediatric patients and the elderly; see Maternal/Child and Elderly. ■ Can cause severe chemical irritation and tissue damage regardless of route of administration. Irritation and damage can result from perivascular extravasation, unintentional intra-arterial injection, and intraneuronal or perineuronal infiltration. Adverse event reports include abscesses, burning, erythema, gangrene, pain, palsies, paralysis, sensory loss, severe spasm of the distal vessels, swelling, thrombophlebitis, tissue necrosis, and venous thrombosis. ■ Use should be avoided in patients with compromised respiratory function or in patients at risk for respiratory failure (e.g., COPD, sleep apnea); risk of potentially fatal respiratory depression is increased. ■ May cause paradoxical excitation in pediatric patients and the elderly. ■ Use with caution in patients with bladder neck obstruction, cardiovascular disease, narrow-angle glaucoma, liver dysfunction, prostatic hypertrophy, pyloroduodenal obstruction, or stenosing peptic ulcer. ■ May produce ECG changes (e.g., prolonged QT interval, changes in T waves). ■ May lower seizure threshold; use extreme caution in patients with known seizure disorders and with narcotics or local anesthetics that also lower seizure threshold. ■ May contain sulfites; use caution in patients with allergies. ■ Neuroleptic malignant syndrome (NMS), a rare syndrome manifested by hyperpyrexia, muscle rigidity, altered mental status, and autonomic instability (irregular BP and HR, tachycardia, diaphoresis, and cardiac dysrhythmias) has been reported in association with promethazine alone or in combination with antipsychotic drugs. ■ Cholestatic jaundice has been reported.

Monitor:

A vesicant; determine absolute patency of vein; extravasation will cause necrosis; see Contraindications and Precautions. ISMP suggests administering through large-bore veins. Administration through hand or wrist veins is strongly discouraged. ■ Monitor frequently for S/S of extravasation (e.g., burning, erythema, pain, palsies, sensory loss, and swelling along IV site), especially along peripheral sites. ■ Monitor for CNS effects (e.g., extrapyramidal effects, sedation). ■ Sedative effect may require ambulation to be monitored. ■ See Drug/Lab Interactions.

Patient Education:

Avoid use of alcohol or other CNS depressants (e.g., antihistamines, barbiturates). ■ Request assistance for ambulation; may cause dizziness or fainting. ■ Use caution performing tasks that require alertness. ■ May cause skin and eye photosensitivity. Avoid unprotected exposure to sun. ■ Report stinging or burning at IV site promptly. ■ Report any involuntary muscle movements.

Maternal/Child:

Category C: safety for use in pregnancy and pediatric patients not established. Use only when clearly needed. ■ Discontinue breast-feeding. ■ Contraindicated in pediatric patients under 2 years of age. Post-marketing cases of respiratory depression and death have been reported. Concomitant administration with other respiratory depressants increases this risk. ■ Use caution in pediatric patients 2 years of age or older. Use the minimum effective dose. ■ Do not use for vomiting of unknown etiology in pediatric patients. Antiemetics are not recommended for treatment of uncomplicated vomiting in pediatric patients. Use should be limited to prolonged vomiting of known etiology. ■ Extrapyramidal symptoms that can occur secondary to promethazine administration may be confused with CNS signs of an undiagnosed primary disease (e.g., encephalopathy or Reye's syndrome). Avoid use in pediatric patients with S/S suggestive of Reye's syndrome or other hepatic diseases. ■ Excessively large doses of antihistamines in pediatric patients have caused sudden death. Hallucinations and convulsions have occurred with therapeutic doses and overdoses. Incidence of extrapyramidal reactions is increased in pediatric patients, especially in the presence of acute illness (e.g., measles, chickenpox, gastroenteritis). ■ See Precautions and Contraindications.

Elderly:

See Dose Adjustments and Precautions. ■ May exhibit increased sensitivity to adverse effects, including anticholinergic (e.g., dry mouth, urinary retention), CNS, and extrapyramidal (e.g., tardive dyskinesia, parkinsonism) side effects.

DRUG/LAB INTERACTIONS

Promethazine may increase, prolong, or intensify the sedative action of **CNS depressants**. Avoid concurrent use or administer CNS depressants in reduced dosage. The dose of barbiturates should be reduced by at least one-half, and the dose of narcotics should be reduced by one-fourth to one-half. Dosage must be individualized. ■ Additive effects with **MAO inhibitors, anticholinergics, antihistamines, antihypertensives, hypnotics,** and **muscle relaxants**; monitor for adverse effects. ■ Use with epinephrine not recommended; may cause precipitous hypotension. ■ Concurrent use with **other neuroleptic agents** (e.g., haloperidol) may increase the risk of NMS. ■ Capable of innumerable other interactions. ■ Selected **pregnancy tests** may show a false-negative or false-positive result. ■ May cause an increase in blood glucose; consider when a **glucose tolerance test** is indicated.

SIDE EFFECTS

Angioneurotic edema, apnea, asthma, blurred vision, bradycardia, confusion, dermatitis, disorientation, dizziness, drowsiness, dryness of mouth, extrapyramidal symptoms, faintness, hallucinations, hematologic side effects (e.g., agranulocytosis, leukopenia, thrombocytopenia, thrombocytopenic purpura), hypersensitivity reactions, hypertension, halypotension, jaundice, nasal stuffiness, nausea, neuroleptic malignant syndrome, paradoxical reactions (e.g., abnormal movements, agitated behavior, delirium, hyperexcitability, nightmares), photosensitivity, respiratory depression, sedation, severe tissue injury (including gangrene), somnolence, tachycardia, urticaria, vomiting.

Overdose:

Ataxia, athetosis, atropine-like S/S (e.g., dry mouth; fixed, dilated pupils; flushing), Babinski reflex, convulsions, deep sedation, GI symptoms, hyperreflexia, hypertonia, profound hypotension, respiratory depression, unconsciousness, and sudden death.

ANTIDOTE

Discontinue the drug immediately at onset of any side effect and notify the physician. Sympathetic block and heparinization have been used during acute management of promethazine extravasation (unintentional intra-arterial injection or perivascular extravasation). In some cases surgical intervention, including fasciotomy, skin graft, and/or amputation, has been required. Treatment of overdose is essentially symptomatic and supportive. Counteract hypotension with IV fluids, Trendelenburg position, norepinephrine, or phenylephrine; counteract extrapyramidal symptoms with benztropine mesylate or diphenhydramine. Epinephrine is contraindicated for hypotension; further hypotension will occur. Use diazepam or phenobarbital for convulsions or hyperactivity. Treatment of NMS includes discontinuation of all unnecessary drugs and intensive symptomatic treatment and monitoring. Dialysis does not appear to be helpful in overdose situations. Resuscitate as necessary.

PROPOFOL INJECTION

(**PROH**-poh-fohl in-**JEK**-shun)
Diprivan
General anesthetic
Anesthesia adjunct
Sedative
pH 7 to 8.5

USUAL DOSE

Pretreatment:

Fluid correction required; see Monitor.

Lidocaine may be administered to minimize pain on injection of propofol. Administer before propofol injection or add to propofol immediately before administration. Do not exceed more than 20 mg lidocaine to 200 mg propofol.

Sedation of Intubated, Mechanically Ventilated ICU Patients

Must be individualized and titrated to desired response. Given as a continuous infusion. Begin with an initial dose of 5 mcg/kg/min (0.3 mg/kg/hr) for 5 minutes. Allow at least 5 minutes between adjustments to reach peak drug effect and to avoid hypotension. Increase slowly over 5 to 10 minutes by 5 to 10 mcg/kg/min (0.3 to 0.6 mg/kg/hr) to desired level of sedation. Individualize to patient condition, response, blood lipid profile, and vital signs. Administration should not exceed 4 mg/kg/hr unless the benefits outweigh the risks. Some clinicians recommend reducing dose by approximately one-half for elderly (over 55 years) and debilitated. Check urinalysis and urine sediment before administration of propofol in patients at risk for renal failure; see Precautions and Monitor.

Maintenance of Sedation in Mechanically Ventilated or Respiratory-

Controlled ICU Patients

5 to 50 mcg/kg/min (0.3 to 3 mg/kg/hr) or higher as a continuous infusion slowly titrated to desired level of sedation. Use caution with doses higher than 50 mcg/kg/min; may increase risk of hypotension. Bolus doses of 10 to 20 mg may be used to rapidly increase the depth of sedation in patients in whom hypotension is not likely to occur. Temporarily reduce dose once each day to assess neurologic and respiratory function and to determine minimum dose required for desired level of sedation. Average maintenance dose ***under 55 years*** is 38 mcg/kg/min; ***over 55 years,*** 20 mcg/kg/min. Average maintenance dose for ***post–coronary artery bypass graft (CABG) patients*** is usually low (median of 11 mcg/kg/min) because of high intraoperative opiates.

Relief of Pruritus Associated with Use of Spinal Opiates or Cholestasis (Unlabeled)

Subhypnotic doses of 10 to 15 mg as an IV injection or 0.5 to 1.5 mg/kg/hr as an infusion.

Management of Refractory Status Epilepticus (Unlabeled)

Administer doses of 1 to 2 mg/kg as an IV injection over 5 minutes; may be repeated if seizure activity recurs. If indicated, follow with a maintenance infusion of 2 to 10 mg/hr. Adjust to achieve the lowest rate needed to suppress seizure activity. Decrease gradually to prevent withdrawal seizures.

PEDIATRIC DOSE

To minimize pain on injection of propofol in pediatric patients, administer through larger veins or pretreat smaller veins with lidocaine. See Maternal/Child.

DOSE ADJUSTMENTS

All situations:

Reduced dose required in presence of other CNS depressants. See Drug/Lab Interactions. ■ No dose adjustment required for gender, chronic hepatic cirrhosis, or chronic renal failure.

ICU sedation:

Adjust infusion to maintain a light level of sedation through the wake-up assessment or weaning process.

DILUTION

Supplied in ready-to-use vials containing 10 mg/mL. Shake well before use. Do not use if there is evidence of excessive creaming or aggregation, if large droplets are visible, or if there are other forms of phase separation. Slight creaming, which should disappear after shaking, may be visible with prolonged standing. May be further diluted only with D5W. Do not dilute to a concentration less than 2 mg/mL (4 mL diluent to 1 mL propofol yields 2 mg/mL). More stable in glass than in plastic. Strict aseptic technique imperative; emulsion supports rapid growth of microorganisms. Failure to use strict aseptic technique has been associated with microbial contamination of the product with resultant fever, infection, sepsis, other life-threatening illnesses, and/or death. Prepare immediately before each use. Vials are never to be accessed more than once or used on more than one person because of the possible transmission of bloodborne pathogens (e.g., hepatitis B, hepatitis C, and HIV). Flush IV line at end of every 6 hours in extended procedures to remove residual propofol.

Filters:

Use filters with caution. The pore size should be equal to or greater than 5 microns. Filters with a pore size less than 5 microns may impede the flow of propofol and/or cause a breakdown of the emulsion.

Storage:

Protect from light and store below 22° C (72° F) but do not refrigerate. Discard infusion and tubing every 12 hours or every 6 hours if propofol has been transferred from the original container.

COMPATIBILITY

Manufacturer states, “Should not be mixed with other therapeutic agents prior to administration. **Compatibility** with blood/serum/plasma has not been established.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Use of a syringe pump or volumetric pump recommended to provide controlled infusion rates. See Usual Dose for specific rates for specific age and/or indication. Decrease rate based on age, debilitation, or calculated risk. Must be individualized and titrated to desired level of sedation and changes in vital signs. Monitor respiratory function continuously. Continuous administration preferable to intermittent to avoid periods of undersedation or oversedation. Too-rapid administration (bolus dosing, too-rapid increase in infusion rate, overdose) can cause severe cardiorespiratory complications, especially in pediatric patients, adults over 55 years, debilitated or ASA III or IV risk patients. In all anesthesia, higher rates are generally required for the first 15 minutes, then appropriate responses can usually be maintained with a decrease of 30% to 50%. Always titrate rates downward until there is a mild response to surgical stimulation. This avoids administration at rates higher than clinically necessary. Control increased response to surgical stimulation or lightening of anesthesia (increased pulse rate, BP, sweating and/or tearing) with bolus injections of 25 to 50 mg ***(adults under 55 years of age only),*** slow injection of reduced doses, or by increasing the infusion rate ***(adults under or over 55 years of age)*** or by increasing the infusion rate ***(pediatric patients).*** If control not effective within 5 minutes, consider use of an opioid, barbiturate, or inhalation agent.

ACTIONS

A potent emulsified IV general anesthetic and sedation drug. Mechanism of action is poorly understood. Propofol is thought to produce its sedative/anesthetic effects by the positive modulation of the inhibitory function of the neurotransmitter GABA through the ligand-gated $GABA_A$ receptors. Can provide conscious (verbal contact maintained) or unconscious sedation depending on dose. Induces anesthesia rapidly and smoothly with minimal excitation, usually within 40 seconds. Depth of sedation easily and rapidly controlled by adjusting rate of infusion. Rapid onset of action facilitates accurate titration and minimizes oversedation. Due to extensive redistribution from the central nervous system to other tissues and high metabolic clearance, recovery from anesthesia or sedation is rapid. Time to awakening is dependent on duration of infusion. Discontinuation of an infusion after maintenance of anesthesia for 1 hour or sedation in the ICU for 1 day will result in rapid awakening. Prolonged infusions (e.g., 10 days in ICU) will result in drug accumulation and an increased time to awakening. By daily titration of the propofol dose to achieve only the minimum effective therapeutic concentration, rapid awakening within 10 to 15 minutes can occur even after long-term administration. Terminal half-life is 4 to 7 hours but may be up to 1 to 3 days after a 10-day infusion. Metabolized in the liver and excreted as metabolites in urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Adults:

Induce and/or maintain anesthesia as part of a balanced anesthetic technique for inpatient and outpatient surgery. ■ Initiate and maintain monitored anesthesia care (MAC) during diagnostic procedures (e.g., colonoscopy, dental procedures) and in conjunction with local/regional anesthesia during surgical procedures. ■ Continuous sedation and control of stress responses in intubated, mechanically ventilated ICU patients (e.g., post-CABG, postsurgical, neuro/head trauma, ARDS, COPD, asthma, status epilepticus, tetanus). Continuous infusion of low doses allows controlled recovery of consciousness when required and for assessment.

Pediatric patients:

Induction of anesthesia as a part of a balanced anesthetic technique for inpatient and outpatient surgery in pediatric patients over 3 years of age. ■ Maintenance of anesthesia as part of a balanced anesthetic technique for inpatient and outpatient surgery in pediatric patients over 2 months of age. ■ Not recommended for induction of anesthesia for pediatric patients under 3 years of age or for maintenance of anesthesia under 2 months of age. ■ Not indicated for use in pediatric patients for ICU sedation or for MAC sedation for surgical, nonsurgical, or diagnostic procedures.

Unlabeled uses:

Subhypnotic doses used for relief of pruritus associated with use of spinal opiates or cholestasis; treatment of status epilepticus refractory to standard anticonvulsant therapy.

CONTRAINDICATIONS

Known hypersensitivity to propofol or its components (e.g., soybean oil, glycerol, egg lecithin, sodium hydroxide) or any time general anesthesia or sedation is contraindicated.

PRECAUTIONS

All situations:

For IV use only. ■ Administered by or under the direct observation of the anesthesiologist. Must have responsibility only for anesthesia during surgery and/or procedures. In the ICU setting, may be administered to intubated, mechanically ventilated patients by persons skilled in medical management of critically ill patients and trained in cardiovascular resuscitation and airway management. Both life-threatening and fatal anaphylactoid and anaphylactic reactions have been reported. ■ Strict aseptic technique required; see Dilution. ■ Use caution in patients with compromised myocardial function, intravascular volume depletion, or abnormally low vascular tone (e.g., sepsis); may be more susceptible to hypotension. ■ Avoid rapid bolus administration in the elderly, debilitated, or ASA-PS III or IV patients. May cause undesirable cardiopulmonary depression, including apnea, airway obstruction, hypotension, and oxygen desaturation. ■ An emulsion; use caution in patients with lipid metabolism disorders (e.g., diabetic hyperlipidemia, pancreatitis, and primary hyperlipoproteinemia). ■ May cause convulsions during recovery phase in patients with epilepsy. ■ Use caution in patients with increased intracranial pressure or impaired cerebral circulation. Decrease in mean arterial pressure may cause decreases in cerebral perfusion. ■ Propofol infusion syndrome has been reported and is characterized by severe metabolic acidosis, hyperkalemia, lipemia, rhabdomyolysis, hepatomegaly, renal failure, and ECG changes and/or cardiac failure. Major risk factors for the development of these events include decreased oxygen delivery to tissues; serious neurologic injury and/or sepsis; high dosages of one or more of the following pharmacologic agents: vasoconstrictors, steroids, or inotropes; and/or prolonged, high-dose infusions of propofol (greater than 5 mg/kg/hr for more than 48 hours). Deaths have occurred. Consider alternative means of sedation when there is a prolonged need for sedation, when large doses of propofol are required to maintain a desired level of sedation, or if a patient develops metabolic acidosis. ■ Has no analgesic properties; provide pain relief or local anesthetic as indicated. Has been used successfully with midazolam (Versed), 1 to 3 mg, for initial induction. Midazolam provides better amnesia and causes less pain on injection, whereas propofol sustains sedation and allows more rapid recovery. ■ May contain sulfites; use caution in patients with allergies. ■ Abuse of propofol for recreational and other improper purposes has resulted in fatalities and other injuries. ■ See Maternal/Child.

Monitor:

All situations:

Correct fluid volume deficiencies before administration. ■ Will cause transient local pain during IV injection; minimize by using larger veins and lidocaine previous to injection. Use with midazolam reduces awareness of this pain. ■ Apnea may occur during induction and last for more than 60 seconds. Intubation equipment, controlled ventilation equipment, oxygen, and facilities for resuscitation and life support must be available. Maintain a patent airway and ascertain adequate ventilation at all times. ■ All vital signs must be monitored continuously. Use of a respiratory monitor required. ■ Hypotension common during first 60 minutes; monitor closely. Significant hypotension or cardiovascular depression can be profound. ■ To prevent profound bradycardia, anticholinergic agents (e.g., atropine, glycopyrrolate) may be required to modify increases in vagal tone due to concomitant agents (e.g., succinylcholine) or surgical stimulation. ■ Bed rest required for a minimum of 3 hours after IV injection, or satisfy specific hospital rules for discharge. ■ See Precautions and Drug/Lab Interactions.

ICU sedation:

Observe for signs and symptoms of pain; may indicate need for opioids or analgesia, not an increase in propofol dose. ■ Benzodiazepines (e.g., diazepam) and/or neuromuscular blocking agents (e.g., atracurium, succinylcholine) may also be used. ■ Monitor triglycerides with long-term use (ICU sedation). Adjust if fat is inadequately cleared from body, and reduce other lipid administration. 1 mL of propofol contains approximately 0.1 Gm of fat (1.1 kcal). ■ Dose may be reduced carefully to allow patient to awaken to a lighter level of sedation, allowing neurologic and respiratory assessment daily. Avoid rapid awakening; will cause anxiety, agitation, and resistance to mechanical ventilation. ■ Monitor urinalysis and urine sediment on alternate days in patients at risk for renal impairment. ■ Some formulations contain EDTA, a trace metal chelator. Formulations containing EDTA should not be infused for longer than 5 days without providing a drug holiday to safely replace estimated or measured zinc losses. Consider zinc supplementation in patients who may be predisposed (e.g., patients with burns, diarrhea, or major sepsis). ■ Discontinue opioids and paralytic agents and optimize respiratory function before weaning from mechanical ventilation. ■ Maintain light sedation until 15 minutes before extubation.

Patient Education:

Avoid alcohol or other CNS depressants (e.g., antihistamines, benzodiazepines) for 24 hours following anesthesia. ■ Do not perform tasks requiring mental alertness (e.g., driving, operating hazardous machinery, or signing legal documents) until the day after surgery or longer. All effects must have subsided. ■ Discuss with parents or caregivers the risks, benefits, timing, and duration of surgery or procedures requiring anesthetic and sedation drugs; see Maternal/Child.

Maternal/Child:

Use during pregnancy only if clearly needed. ■ Not recommended for use in obstetric procedures, including cesarean section; no assurance of safety for fetus. ■ Not recommended for use during breast-feeding. ■ Has been approved for induction of anesthesia in pediatric patients 3 years to 16 years of age. Has been approved for maintenance of anesthesia in pediatric patients 2 months to 16 years of age. ■ Distribution and clearance in pediatric patients 3 years to 12 years of age is similar to that seen in adults. ■ Published studies suggest that repeated or prolonged exposures to anesthetic agents in utero (third trimester) and early in life (up to 3 years of age) may have negative effects on the developing brain, resulting in adverse cognitive or behavioral effects; see prescribing information for further discussion. Balance the benefits of appropriate anesthesia in pregnant women, neonates, and young children who require procedures with the potential risks described. ■ Serious bradycardia may result with concomitant administration of fentanyl. ■ Serious adverse effects (e.g., metabolic acidosis) occurred during ICU sedation in pediatric patients with respiratory infections and/or with doses in excess of recommendations for adults. Fatalities have occurred. ■ A recent study identified an increase in deaths with propofol versus standard sedative agents. Manufacturer has issued a warning letter stating that propofol should not be used for sedation of pediatric patients in ICU. ■ See Side Effects.

Elderly:

Dose requirements decrease after age 55 due to reduced clearance and volume distribution and higher blood levels. Minimize undesirable cardiorespiratory depression (hypotension, apnea, airway obstruction, and/or oxygen desaturation) by using reduced doses and rates of administration. Avoid rapid single or repeated bolus doses; see Precautions. See Usual Dose and Dose Adjustments.

DRUG/LAB INTERACTIONS

Potentiated by **inhalational anesthetics, narcotics,** and **sedatives**. Anesthetic and sedative effects increased; systolic, diastolic, mean arterial pressure, and cardiac output are decreased. Dose adjustment may be indicated with concomitant use. ■ Competition for chemoreceptor binding sites may occur if used in combination with **droperidol;** use of propofol as a single agent is suggested to control nausea and vomiting. ■ In pediatric patients, serious bradycardia may result with concomitant administration of **fentanyl.** ■ Concomitant use with **valproate** may lead to increased blood levels of propofol. Reduce the dose of propofol when coadministering with valproate. Monitor for signs of increased sedation or cardiorespiratory depression.

SIDE EFFECTS

Adults and pediatric patients:

More likely to occur during loading boluses, with supplemental boluses, or during higher rate of administration. Apnea; bradycardia (profound); cough; dyspnea; headache; hypotension; hypoventilation; injection site burning, pain, stinging; nausea; and upper airway obstruction are most common. Urine may be green. Abdominal cramping, anaphylaxis (including bronchospasm, erythema, and hypotension), bucking/jerking/thrashing, clonic/myoclonic movement (rarely including convulsions and opisthotonos), dizziness, fever, flushing, hiccups, hypertension, tingling/numbness/coldness at injection site, twitching, and vomiting may occur.

Pediatric patients:

Increased incidences of agitation, bradycardia, and jitteriness have occurred; apnea has been observed frequently. Abrupt discontinuation following prolonged infusion may result in agitation, flushing of the hands and feet, hyperirritability, and tremulousness.

Overdose:

Cardiorespiratory depression (hypotension, apnea, airway obstruction, and/or oxygen desaturation).

ANTIDOTE

Keep physician informed of all side effects. Reduction of dose may be required or will be treated symptomatically. Discontinue the drug for major side effects, paradoxical reactions, or accidental overdose. A short-acting drug, a patent airway, and continuous controlled ventilation with oxygen until normal function assured should be adequate. Treat bradycardia and/or hypotension with increased rate of IV fluids, Trendelenburg position, vasopressors. Anticholinergic agents (e.g., atropine or glycopyrrolate) may be required. Treat hypersensitivity reactions and resuscitate as necessary.

PROPRANOLOL HYDROCHLORIDE

(proh-**PRAN**-oh-lohl hy-droh-**KLOR**-eyed)
Beta-adrenergic blocking agent
Antiarrhythmic
pH 2.8 to 3.5

USUAL DOSE

1 to 3 mg given 1 mg at a time under careful monitoring (e.g., CVP, ECG); see Monitor and Rate of Administration. Do not give additional propranolol if desired change in rate or rhythm is achieved. If there is no change in rhythm for at least 2 minutes after initial dose, cycle may be repeated one time. (AHA recommends 0.5 to 1 mg over 1 minute, repeated as needed up to a total dose of 0.1 mg/kg.) ***No further propranolol may be given by any route for at least 4 hours.*** Best results achieved if administered within 2 to 4 hours of symptom onset or thrombolytic therapy. Transfer to oral therapy as soon as possible.

PEDIATRIC DOSE (UNLABELED)

0.01 to 0.1 mg/kg/dose over 10 minutes. Maximum dose is 1 mg for infants and 3 mg for other pediatric patients. Repeat at 6- to 8-hour intervals if needed.

Tetralogy spells (hypercyanotic spells):

0.15 to 0.25 mg/kg/dose may be given slowly. May repeat once in 15 minutes. Another source recommends 0.01 to 0.2 mg/kg/dose. Should not exceed 5-mg dose.

DOSE ADJUSTMENTS

Lower-end initial doses may be indicated in the elderly based on potential for decreased organ function and concomitant disease or drug therapy. ■ Consider dose reduction in patients with impaired hepatic function. ■ See Drug/Lab Interactions. ■ Reduce dose gradually to avoid rebound angina, myocardial infarction, or ventricular arrhythmias.

DILUTION

May be given undiluted; however, further dilution of each 1 mg in 10 mL D5W or NS is preferred to facilitate titration of an exact dose while monitoring effect. May be diluted in 50 mL of D5W, D5/½NS, D5NS, or NS for infusion.

Storage:

Store at CRT. Protect from freezing or excessive heat.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each 1 mg or fraction thereof must be given over 1 minute to avoid excessive hypotension and/or cardiac standstill. A single dose may be given as an infusion over 10 to 15 minutes. Allow adequate time for distribution; consider slow circulation time. Observe monitor and discontinue propranolol as soon as rhythm change occurs.

Pediatric rate:

Extend rate of administration of a single dose by injection to a minimum of 5 minutes in pediatric patients.

ACTIONS

Propranolol is a nonselective beta-adrenergic blocker with antiarrhythmic effects. Cardiac response to sympathetic nerve stimulation is inhibited, slowing the HR (especially ventricular rate) by inhibiting atrioventricular conduction. Decreases the force of cardiac contractility, and decreases arterial pressure and cardiac output. Blockade of beta_2-adrenergic receptors found predominantly in smooth muscle (e.g., vascular, bronchial, gastrointestinal, and genitourinary); leads to constriction in these tissues. Well distributed throughout the body, the onset of action occurs within 1 to 2 minutes and lasts about 4 hours. Half-life is 2 to 5.5 hours. Metabolized in the liver. Excreted primarily in the urine. Secreted in breast milk.

INDICATIONS AND USES

Reserve IV use for life-threatening situations or for those occurring under anesthesia. ■ Short-term treatment to decrease ventricular rate in supraventricular tachycardia, including Wolff-Parkinson-White syndrome and thyrotoxicosis. ■ Treatment of persistent and symptomatic PVCs that do not respond to conventional measures. ■ Use in patients with atrial flutter or atrial fibrillation should be reserved for arrhythmias unresponsive to standard therapy or when more prolonged control is required. ■ Control of ventricular rate in life-threatening, digoxin-induced arrhythmias (severe bradycardia may occur). ■ Treatment of tachyarrhythmias due to excessive catecholamine action during anesthesia when other measures fail. ■ Not the drug of first choice for treatment of ventricular arrhythmias unless arrhythmia is induced by catecholamines or digoxin. In critical situations, when cardioversion or other drugs are not indicated or effective, propranolol may be used with caution. (Use a low dose and administer very slowly so the failing heart maintains some sympathetic drive to maintain myocardial tone. May respond with NSR, but a reduction in ventricular rate is more likely.) ■ Numerous other uses PO.

Unlabeled uses:

Other beta-blockers (e.g., atenolol, esmolol) have been used in the perioperative period to reduce cardiac morbidity and mortality in patients at risk; propranolol was not used in these studies. ■ Has been used for adjunctive treatment of pheochromocytoma following primary treatment with an alpha-adrenergic blocking agent (e.g., phenoxybenzamine, phentolamine) and for treatment of other refractory arrhythmias when benefit outweighs risk.

CONTRAINDICATIONS

Cardiogenic shock, sinus bradycardia, greater than first-degree heart block, bronchial asthma, known hypersensitivity to propranolol.

PRECAUTIONS

Oral administration is preferred. Use IV administration only when necessary. ■ Not considered the drug of choice for arrhythmias in myocardial infarction. ■ Used concurrently with digoxin or alpha-adrenergic blockers as indicated. ■ Use with caution in overt CHF. May precipitate more severe failure. ■ Use with extreme caution in asthmatics or in patients with lung disease or bronchospasm; can block bronchodilation produced by endogenous and exogenous catecholamine stimulation of beta receptors. ■ Use with caution in patients with diabetes or in patients with a history of hypoglycemia. May cause hypoglycemia and mask the symptoms. ■ Beta-blockade can mask symptoms of hyperthyroidism. Abrupt withdrawal of propranolol may be followed by exacerbation of symptoms, including thyroid storm. ■ Use caution in patients with hepatic or renal impairment. ■ May cause arrhythmia, angina, MI, or death if stopped abruptly. ■ Beta-adrenergic receptor blockade can cause a reduction in intraocular pressure. Withdrawal of propranolol may lead to a return of elevated intraocular pressure. May also interfere with the screening test for glaucoma. ■ IV dose used during surgery to replace an oral dose should be one-tenth of the oral dose. ■ May cause severe bradycardia in patients with Wolff-Parkinson-White syndrome. See Drug/Lab Interactions.

Monitor:

Continuous ECG and BP monitoring is mandatory during administration of IV propranolol. Monitoring of pulmonary wedge pressure or central venous pressure is recommended. Discontinue the drug when a rhythm change is noted and wait to note full effect before giving additional medication if indicated. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Report any breathing difficulty promptly.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding and in pediatric patients not established. Use only when clearly indicated. ■ Bradycardia, hypoglycemia, and respiratory depression have been seen in neonates whose mothers received propranolol during labor or delivery.

Elderly:

Lower-end initial doses may be indicated; see Dose Adjustments. ■ Response of elderly versus younger patients not documented. ■ Use with caution in age-related peripheral vascular disease; risk of hypothermia increased. ■ May exacerbate mental impairment.

DRUG/LAB INTERACTIONS

Metabolism involves multiple pathways in the **cytochrome P_{450} system.** Interactions with inhibitors, inducers, or substrates of this system are documented. ■ Blood levels of propranolol **increased** when administered concurrently **with substrates or inhibitors** such as amiodarone, cimetidine, ciprofloxacin, delavirdine, fluconazole, fluoxetine, fluvoxamine, imipramine, isoniazid, paroxetine, quinidine, ritonavir, rizatriptan, teniposide, theophylline, tolbutamide, zileuton, zolmitriptan. ■ Blood levels of propranolol **decreased** when administered concurrently with **inducers** such as cigarette smoke, ethanol, and rifampin. ■ Concurrent use with **propafenone** may produce additive negative inotropic and beta-blocking effects. ■ Concurrent administration with **quinidine** results in additive negative inotropic effects and beta-blockade and postural hypotension. ■ Concurrent use with **disopyramide** has been associated with additive hypotension, severe bradycardia, asystole, and heart failure. ■ Concurrent use with **amiodarone** results in additive negative chronotropic properties. ■ Decreases **lidocaine** clearance; lidocaine toxicity has been reported with concurrent use. ■ Effects additive when given with **other agents that slow A-V nodal conduction** (e.g., digoxin, lidocaine). ■ Concurrent use with **calcium channel blockers** that have negative inotropic and/or chronotropic activity (e.g., diltiazem, verapamil) may further depress myocardial contractility and A-V nodal conduction. Bradycardia, heart failure, and cardiovascular collapse have been reported with verapamil and beta-blockers. Bradycardia, hypotension, heart block, and heart failure have been reported with coadministration of diltiazem and beta-blockers. ■ Antihypertensive effects of **clonidine** may be antagonized by propranolol. Use with clonidine may precipitate acute hypertension or aggravate rebound hypertension if clonidine is stopped abruptly; discontinue propranolol several days before gradual withdrawal of clonidine. Monitor BP with concurrent use. ■ First-dose hypotension may be prolonged with **prazosin**. Postural hypotension has been reported when used concurrently with **doxazosin and terazosin**. ■ Coadministration with **reserpine** (a catecholamine-depleting drug) may result in hypotension, bradycardia, vertigo, syncope, or orthostatic hypotension. ■ Avoid concurrent use with **epinephrine.** Beta-blockade may lead to unopposed alpha-receptor stimulation, resulting in uncontrolled hypertension. ■ **Dobutamine or isoproterenol** may be administered to reverse the effects of propranolol. However, patients may experience protracted, severe hypotension. ■ **ACE inhibitors** (enalapril, lisinopril) may increase bronchial hyperactivity when given concurrently with propranolol. ■ Hypotension and cardiac arrest have been reported with concurrent use of **haloperidol** and propranolol. ■ Propranolol may increase serum levels of **theophylline and diazepam**. ■ Potentiates **ergot alkaloids**; monitor for peripheral ischemia; reduce ergot dose or discontinue beta-blocker. ■ Added hypotensive effect with **diuretics** (e.g., furosemide), **other antihypertensive agents** (e.g., enalapril, nitroglycerin), some **phenothiazines** (e.g., chlorpromazine), **and reserpine.** Reduced dose of one or both drugs may be indicated. ■ May prolong effects of **nondepolarizing muscle relaxants** (e.g., pancuronium). ■ May increase anticoagulant effects of **warfarin.** ■ May mask symptoms of hypoglycemia with **insulin and sulfonylureas** and result in prolonged hypoglycemia. ■ Can interfere with **numerous diagnostic and physiologic tests.** Consult literature. ■ May alter **thyroid function tests** and cause **elevations in BUN, serum potassium, triglycerides, serum transaminases, and alkaline phosphatase.** ■ Metabolism and release of catecholamines increased in **smokers;** increased doses may be required. May also interfere with therapeutic effects in **treatment of angina.** ■ Patients taking beta-blockers who are exposed to a potential allergen may be unresponsive to the usual dose of **epinephrine** used to treat a hypersensitivity reaction.

SIDE EFFECTS

AV conduction delays, bradyarrhythmias, bronchospasm, cardiac failure, cardiac standstill, erythematous rash, hallucination, hypotension, laryngospasm, nausea, paresthesia of the hands, respiratory distress, syncopal attacks, vertigo, visual disturbances. Many other side effects have been reported with oral propranolol and could be seen with the IV route; see manufacturer’s literature.

ANTIDOTE

For any side effect or excessive dosage, discontinue the drug and notify the physician immediately. Treat bradycardia with atropine 0.25 to 1 mg. Isoproterenol may be used with caution if no response to vagal blockade. Serious bradycardia may require pacing. Treat cardiac failure with digitalization and diuretics. Treat hypotension or depressed myocardial function with glucagon. Administer 50 to 150 mcg/kg IV followed by an infusion of 1 to 5 mg/hr (see glucagon monograph for correct dilution). Isoproterenol (Isuprel) and dopamine may also be useful; see Drug/Lab Interactions. Treat bronchospasm with isoproterenol and aminophylline. Treat other side effects symptomatically. Monitor ECG, HR, neurobehavioral status, and intake and output until stable. Not significantly removed by hemodialysis or peritoneal dialysis. Resuscitate as necessary.

PROTAMINE SULFATE BBW

(**PROH**-tah-meen **SUL**-fayt)
Antidote (heparin antagonist)
pH 6 to 7

USUAL DOSE

Following a serious heparin overdose, discontinue heparin and administer protamine immediately.

Pretreatment:

Corticosteroids and antihistamines can be used for patients at risk for protamine hypersensitivity.

IV heparin overdose:

1 mg of IV protamine neutralizes approximately 100 USP units of heparin. May be repeated if needed in 10 to 15 minutes. Never exceed 50 mg in any 10-minute period. Dose adjusted as indicated by coagulation studies. Any dose over 100 mg in 2 hours should be justified by coagulation studies (has its own anticoagulant effect). Because heparin disappears rapidly from the circulation, the dose of protamine required decreases rapidly with the time elapsed after heparin injection (e.g., 30 minutes after IV heparin, 0.5 mg [or one-half of the dose] of protamine may be sufficient to neutralize 100 USP units of heparin).

Subcutaneous heparin overdose:

1 to 1.5 mg IV protamine per 100 units of heparin. Some clinicians recommend a loading dose of 25 to 50 mg given slowly over 10 minutes followed by administration of the remainder of the calculated dose as a continuous infusion over 8 to 16 hours (the continuous infusion covers the absorption time seen with administration of SC heparin). See comments under IV heparin overdose.

Low-molecular-weight heparin overdose (unlabeled):

1 mg IV protamine for every 100 antifactor Xa units of LMWH. If PTT remains prolonged 2 to 4 hours after the first dose, or if bleeding continues, consider administration of a second dose of 0.5 mg protamine for every 100 anti-factor Xa units. Only 60% to 75% of anti-factor Xa activity is neutralized. Excessive protamine doses can worsen bleeding potential. See comments under IV heparin overdose.

DOSE ADJUSTMENTS

Because heparin disappears rapidly from the system, reduce dose of protamine based on length of time elapsed since heparin dose (up to one-half if 30 minutes has elapsed). ■ Prompt administration of protamine may also decrease dose requirements.

DILUTION

May be given undiluted or may be further diluted with NS or D5W.

Storage:

Store at CRT. Do not freeze. Discard remaining medication or diluted solution.

COMPATIBILITY

Manufacturer recommends not mixing with other drugs unless **compatibility** is known, and lists as **incompatible** with some antibiotics, including several cephalosporins and penicillins. Consider individualized rate adjustment necessary to produce desired effects.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

50 mg (5 mL) or fraction thereof over 10 minutes. Do not exceed 50 mg in 10 minutes. As an infusion, may be given over 2 to 3 hours with dosage titrated according to coagulation studies. Increase duration of infusion to 8 to 16 hours for treatment of SC heparin overdose. Use infusion pump or microdrip (60 gtt/mL) to administer. Too-rapid administration, high doses, or repeated doses can cause anaphylaxis, bradycardia, cardiovascular collapse, catastrophic pulmonary vasoconstriction, pulmonary hypertension, dyspnea, flushing, noncardiogenic pulmonary edema, sensation of warmth, or severe hypotension. Hypertension has also occurred.

ACTIONS

An anticoagulant if administered alone. In the presence of heparin, protamine forms a stable salt, neutralizing the anticoagulant effect of both drugs. Does not bind to low-molecular-weight fragments of LMWH preparations, leading to incomplete neutralization of anti-factor Xa. Each 1 mg of protamine can neutralize approximately 100 USP units of heparin. Onset of action is within 0.5 to 1 minute. Neutralization of heparin occurs within 5 minutes. Duration of action is about 2 hours.

INDICATIONS AND USES

To neutralize the anticoagulant activity of heparin in severe heparin overdosage.

Unlabeled uses:

Neutralization of heparin administered during extracorporeal circulation in arterial and cardiac surgery or dialysis procedures. ■ Heparin neutralization in pregnant women near delivery. ■ Treatment of overdose of low-molecular-weight heparin (e.g., dalteparin, enoxaparin, tinzaparin). Neutralization of LMWH is not complete.

CONTRAINDICATIONS

Known hypersensitivity to protamine. ■ Do not use for bleeding that occurs without prior exposure to heparin.

PRECAUTIONS

For IV use only. Can cause severe hypotension, cardiovascular collapse, noncardiogenic pulmonary edema, catastrophic pulmonary vasoconstriction, and pulmonary hypertension. Risk factors include high dose or overdose, rapid administration, repeated doses, previous administration of protamine, and current or previous use of protamine-containing drugs (e.g., NPH insulin, protamine zinc insulin, and certain beta-blockers).

Allergy to fish, previous vasectomy (may have antiprotamine antibodies), severe left ventricular dysfunction, and abnormal preoperative pulmonary hemodynamics also may be risk factors. In patients with any of these risk factors, the risk versus benefit of protamine sulfate administration should be carefully considered. See Rate of Administration and Usual Dose. ■ Must be administered in a facility equipped to monitor the patient and respond to any medical emergency. ■ Pulmonary edema and/or circulatory collapse may occur in patients undergoing cardiac bypass surgery; etiology unknown. ■ Protamine sulfate should not be given when bleeding occurs without prior heparin use.

Monitor:

Coagulation studies (e.g., aPTT, ACT, heparin titration test with protamine, plasma thrombin time) may be indicated to monitor therapeutic response. ■ Facilities to treat shock must be available; see Precautions. ■ After cardiac surgery or dialysis procedures, even with adequate neutralization, further bleeding may occur any time within 24 hours (heparin "rebound"). Observe the patient continuously. Additional protamine sulfate may be indicated.

Maternal/Child:

Category C: safety for use in pregnancy, breast-feeding, or pediatric patients not established.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Occur more frequently with too-rapid injection; anaphylaxis, back pain, bradycardia, dyspnea, feeling of warmth, flushing, lethargy, nausea, vomiting, severe hypertension or hypotension. Acute pulmonary hypertension, noncardiogenic pulmonary edema, catastrophic pulmonary vasoconstriction, circulatory collapse, capillary leak, or pulmonary edema may occur.

ANTIDOTE

Discontinue the drug and notify the physician, who may recommend a decrease in rate of administration or, if side effects are severe, symptomatic treatment such as administration of whole blood, vasopressors for hypotension, atropine for bradycardia, and oxygen for dyspnea. Resuscitate as necessary.

PROTEIN AMINO ACIDS, DEXTROSE, FAT EMULSION, AND ELECTROLYTES BBW

(**PROH**-teen ah-**MEE**-noh **AS**-ids)
Kabiven ■ Perikabiven
Nutritional therapy

USUAL DOSE

Pretreatment:

Obtain baseline labs; see Monitor. Correct severe fluid, electrolyte, and acid-base disorders before initiating therapy.

Kabiven:

19 to 38 mL/kg/day. Do not exceed 40 mL/kg/day.

Perikabiven:

27 to 40 mL/kg/day. Do not exceed 40 mL/kg/day.

Maximum infusion rate is based on the dextrose component. Individualize dose based on patient's clinical condition (ability to adequately metabolize amino acids, dextrose, and lipids), on patient's body weight and nutritional/fluid requirements, as well as on additional energy given orally/enterally to the patient. Dosage selection is based on fluid requirements, which can be used in conjunction with the nutritional requirements to determine final dosage. Products meet total nutritional requirements for protein, dextrose, and lipids in stable patients and can be individualized to meet specific needs with the addition of nutrients. Treatment may be continued for as long as is required by the patient's condition.

The recommended daily nutritional requirements for protein, dextrose, and lipids compared to the amount of nutrition provided by each product are shown in the following chart. See Rate of Administration for additional dosing instructions.

Nutritional Comparison

	Nutrition Provided by Kabiven Recommended Dosage	**Nutrition Provided by Perikabiven Recommended Dosage**	**Recommended Nutritional Requirements**	
			Stable Patients	**Critically Ill Patients**[a]
Fluid (mL/kg/day)	19 to 38	27 to 40	30 to 40	Minimum needed to deliver adequate macronutrients
Protein[b] (Gm/kg/day)	0.6 to 1.3	0.64 to 0.94	0.8 to 1	1.5 to 2
Nitrogen (Gm/kg/day)	0.1 to 0.2	0.1 to 0.15	0.13 to 0.16	0.24 to 0.3
Dextrose (Gm/kg/day)	1.9 to 3.7	1.8 to 2.7	≤10	≤5.8
Lipids (Gm/kg/day)	0.7 to 1.5	0.95 to 1.4	1	≤1
Total energy requirement (kcal/kg/day)	16 to 32	18 to 27	20 to 30	25 to 30

[a] Do not use in patients with conditions that are contraindicated; see Contraindications.

[b]Protein provided as amino acids. When infused IV, amino acids are metabolized and utilized as the building blocks of protein.

DOSE ADJUSTMENTS

Stop infusion in patients with a serum triglyceride concentration above 400 mg/dL. Monitor levels. Once serum triglycerides are less than 400 mg/dL, restart infusion at a reduced rate. Advance rate in smaller increments toward target dosage, checking the triglyceride levels before each adjustment. ■ Administer the recommended dosage in patients with renal impairment. Renal patients not needing dialysis require 0.6 to 0.8 Gm of protein/kg/day. Patients undergoing hemodialysis or continuous renal replacement therapy should receive 1.2 to 1.8 Gm of protein/kg/day up to a maximum of 2.5 Gm of protein/kg/day based on nutritional status and estimated protein losses. Dosage may require adjustment based on fluid, protein, and electrolyte requirements in these patients. Adjust dosage based on treatment for renal impairment, supplementing protein as indicated. If required, additional amino acids may be added to the Kabiven or Perikabiven bag or infused separately; see Compatibility. ■ Lower-end initial dosing may be appropriate in the elderly based on the potential for decreased hepatic, renal, or cardiac function and on concomitant disease or drug therapy.

DILUTION

Kabiven and Perikabiven are sterile, hypertonic emulsions in a three-chamber container. The individual chambers contain one of the following, respectively: amino acids and electrolytes, dextrose, or lipid injectable emulsion. Available in multiple volumes. Process of activation is extensive. See manufacturer's prescribing information for **contents** of Kabiven and Perikabiven when mixed and for ***Preparation Instructions*** and ***Instructions for Use.*** An instructional video is available at www.KabivenUSA.com.

Inspect the bag before activation and discard if any of the following conditions exists: there is evidence of damage to the bag, more than one chamber is white, the solution is yellow, or any seal is already broken. ***After activating the bag***, add any **compatible** additives (e.g., MVI and trace elements) via the additive port (white port) using an 18- to 23-gauge needle with a maximum length of 1.5 inches (40 mm). Mix thoroughly after each addition by inverting the bag to ensure a homogenous admixture. Visually inspect for particulate matter and discoloration before administration. Ensure that precipitates have not formed and that the emulsion has not separated. (Separation of the emulsion can be visibly identified by a yellowish streaking or the accumulation of yellowish droplets in the mixed emulsion.)

Filters:

Use of a 1.2-micron in-line filter required.

Storage:

Kabiven and Perikabiven:

Before use, store at CRT. Avoid excessive heat and protect from freezing. If accidentally frozen, discard. Do not remove container from the overpouch until intended for use. Product should be used immediately after mixing and the introduction of additives. If not used immediately, the storage time and conditions before use should not be longer than 24 hours refrigerated at 2° to 8° C (36° to 46° F). After removal from refrigeration, the admixture should be infused within 24 hours. Any mixture remaining must be discarded.

Kabiven:

In the absence of additives, once activated, the product remains stable for 48 hours at 25° C (77° F). If not used immediately, the activated bag can be stored for up to 7 days under refrigeration. After removal from refrigeration, the activated bag should be used within 48 hours.

COMPATIBILITY

Manufacturer states, "Ceftriaxone ***must not be administered*** simultaneously with calcium-containing intravenous solutions such as Kabiven or Perikabiven via a Y-site due to precipitation. However, may be administered sequentially if the infusion lines are thoroughly flushed between infusions with a **compatible** fluid. ***Do not use administration sets and lines that contain DEHP.*** Administration sets that contain polyvinyl chloride (PCV) components have DEHP as a plasticizer."

RATE OF ADMINISTRATION

For IV infusion only. Use a dedicated line without any connections. Multiple connections could result in air embolism. Use a 1.2-micron in-line filter. Use a nonvented infusion set or close the air inlet on a vented set. (Use of a vented intravenous administration set with a vent in the open position could result in air embolism.)

Kabiven:

Maximum infusion rate is 2.6 mL/kg/hr via a **central vein**.

Perikabiven:

Maximum infusion rate is 3.7 mL/kg/hr via a **central or peripheral vein**.

The maximum infusion rates listed correspond to 0.09 Gm/kg/hr of amino acids, 0.25 Gm/kg/hr of dextrose (the rate-limiting factor), and 0.1 Gm/kg/hr of lipids. The recommended duration of infusion is between 12 and 24 hours, depending on the clinical situation.

Dosing Instructions:

1. After determining the fluid requirements to be delivered (see preceding chart in Usual Dose), select the corresponding bag that will supply the correct volume of solution. 2. Determine the preferred duration of infusion (12 to 24 hours). 3. Ensure that the rate of infusion in mL/kg/day divided by the preferred duration of infusion in hours does not exceed the maximum infusion rate for the patient (i.e., 2.6 mL/kg/hr for **Kabiven** and 3.7 mL/kg/hr for **Perikabiven**). The infusion rate may need to be reduced and the duration of infusion increased in order not to exceed the maximum infusion rate. 4.

Once the infusion rate in mL/kg/hr has been selected, calculate the infusion rate (mL/hr) using the patient's weight. 5. Compare the patient's nutrient requirements with the amount supplied by Kabiven or Perikabiven. Discuss any additions that may be required with a pharmacist or dietitian.

Example:

1. A stable, ambulatory 50-kg patient is to receive Kabiven at a rate of 30 mL/kg/day.

   30 mL/kg/day × 50 kg = 1,500 mL/day. A 1,540 mL bag is chosen.

2. To accommodate different therapies, an infusion duration of 12 hours is chosen.
3. Verify that the maximum rate has not been exceeded: 30 mL/kg/day ÷ 12 = 2.5 mL/kg/hr.
4. 2.5 mL/kg/hr × 50 kg = 125 mL/hr.

ACTIONS

Kabiven and Perikabiven are used as a supplement or as the sole source of nutrition in patients, providing macronutrients (amino acids, dextrose, and lipids) and micronutrients (electrolytes) parenterally. The amino acids provide the structural units that make up proteins and are used to synthesize proteins and other biomolecules or are oxidized to urea and carbon dioxide as a source of energy. Dextrose is oxidized to carbon dioxide and water, yielding energy. Lipids provide biologically utilizable sources of calories and essential fatty acids. Fatty acids serve as an important substrate for energy production. Fatty acids are important for membrane structure and function, as precursors for bioactive molecules (such as prostaglandins), and as regulators of gene expression. The disposition of amino acids, dextrose, and electrolytes is essentially the same as those supplied by ordinary food. The elimination and oxidation rates of infused lipids depend on the patient's clinical condition. Elimination is faster and utilization is increased in postoperative patients and with sepsis, burns, and trauma, whereas patients with renal impairment and hypertriglyceridemia may show lower utilization of exogenous lipid emulsions.

INDICATIONS AND USES

Indicated as a source of calories, protein, electrolytes, and essential fatty acids for adult patients requiring parenteral nutrition when oral or enteral nutrition is not possible, is insufficient, or is contraindicated. May be used to prevent essential fatty acid deficiency or to treat negative nitrogen balance.

Limitation of use:

Not recommended for use in pediatric patients under 2 years of age, including preterm infants, because the fixed content of the formulation does not meet the nutritional requirements of this age-group; see Maternal/Child.

CONTRAINDICATIONS

Known hypersensitivity to egg, soybean proteins, peanut proteins, corn or corn products, or any of the active substances or excipients. ■ Severe hyperlipidemia or severe disorders of lipid metabolism characterized by hypertriglyceridemia (serum triglyceride concentration greater than 1,000 Gm/dL). ■ Inborn error of amino acid metabolism. ■ Cardiopulmonary instability (including pulmonary edema, cardiac insufficiency, myocardial infarction, acidosis, and hemodynamic instability requiring significant vasopressor support). ■ Hemophagocytic syndrome.

PRECAUTIONS

For intravenous infusion only. **Kabiven** is indicated for administration into a *central vein* only (e.g., superior vena cava). Infusion of hypertonic nutrient injections into a peripheral vein may result in vein irritation, vein damage, and/or thrombosis. **Perikabiven** may be administered into a *peripheral or central vein*. Peripheral catheters should not be used for solutions with osmolarity of 900 mOsm/L or greater. The primary complication of peripheral access is venous thrombophlebitis. ■ Not recommended for pediatric patients under 2 years of age, including preterm infants; see Maternal/Child. ■ Stop infusion immediately for S/S of hypersensitivity reaction. ■ Patients who require parenteral nutrition are at high risk for infections due to malnutrition and their underlying disease state. Decrease risk of septic complications with a heightened emphasis on aseptic technique in catheter placement and maintenance, as well as with aseptic technique in the preparation of the nutritional formula. ■ A reduced or limited ability to metabolize the lipid contained in Kabiven and Perikabiven accompanied by prolonged plasma clearance may result in fat overload syndrome. Syndrome is characterized by a sudden deterioration in the patient's condition accompanied by fever, anemia, leukopenia, thrombocytopenia, coagulation disorders, hyperlipidemia, liver fatty infiltrations (hepatomegaly), deteriorating liver function, and central nervous system manifestations (e.g., coma). Cause of fat overload syndrome is unclear but is usually reversible with discontinuation of the lipid emulsion. ■ Refeeding syndrome, characterized by the intracellular shift of potassium, phosphorus, and magnesium, may occur when refeeding severely undernourished patients with parenteral nutrition. Thiamine deficiency and fluid retention may also develop. Increase intake gradually to avoid overfeeding and to prevent these complications. ■ Use with caution in patients with diabetes mellitus or hyperglycemia. Hyperglycemia or hyperosmolar syndrome may develop. Administration of dextrose at a rate exceeding the patient's utilization rate may lead to hyperglycemia, coma, and death; see Rate of Administration. ■ Hepatobiliary disorders, including cholecystitis, cholelithiasis, cholestasis, hepatic steatosis, fibrosis, and cirrhosis, possibly leading to hepatic failure, have developed in patients without pre-existing liver disease who receive parenteral nutrition. Increase of blood ammonia levels and hyperammonemia may occur in patients receiving amino acid solutions. May indicate hepatic insufficiency or the presence of an inborn error of amino acid metabolism. A clinician knowledgeable in liver diseases should assess patients developing signs of hepatobiliary disorders. ■ Parenteral nutrition–associated liver disease (PNALD) has been reported in patients receiving parenteral nutrition for extended periods. Exact etiology is unknown; see Antidote. ■ Use with caution in patients with impaired liver function. ■ Use with caution in patients with renal impairment, such as prerenal azotemia, renal obstruction, and protein-losing nephropathy. May be at increased risk for electrolyte and fluid volume imbalance. Patients developing signs of renal impairment should be assessed by a clinician knowledgeable in renal disease. ■ Close monitoring of triglyceride levels is required to avoid consequences associated with hypertriglyceridemia. Serum triglyceride levels above 1,000 mg/dL have been associated with an increased risk of pancreatitis. ■ Impaired lipid metabolism with hypertriglyceridemia may occur with conditions such as inherited lipid disorders, obesity, diabetes mellitus, and metabolic syndrome. In these cases, increased triglycerides can also be increased by dextrose and/or overfeeding; see Monitor and Dose Adjustments. ■ Kabiven and Perikabiven contain no more than 25 mcg/L of aluminum. In impaired kidney function, aluminum may reach toxic levels. Research indicates that patients with impaired renal function who receive greater than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. Tissue loading may occur at even lower rates of administration of total parenteral nutrition products.

Monitor:

Frequent clinical evaluation and laboratory determinations are necessary for proper monitoring during administration. ■ Obtain baseline labs, including electrolytes, serum triglycerides, blood glucose, liver/kidney function (BUN, SCr, liver function tests, ammonia), serum osmolarity, and CBC, including platelet and coagulation parameters. Repeat frequently as indicated by clinical condition. ■ Monitor fluid status closely in patients with heart failure, pulmonary edema, or renal impairment. ■ Evaluate patient’s ability to eliminate and metabolize infused lipid emulsion by measuring serum triglyceride levels at baseline, with each increase in dosage, and regularly throughout treatment. ■ Monitor patients for S/S of essential fatty acid deficiency. Laboratory tests are available to determine serum fatty acid levels. ■ Monitor for S/S of a hypersensitivity reaction (e.g., altered mentation, bronchospasm, chills, cyanosis, dizziness, dyspnea, erythema, fever, flushing, headache, hypotension, hypoxia, nausea, rash, sweating, tachycardia, tachypnea, urticaria, vomiting). ■ Monitor for S/S of early infection (e.g., fever, chills, hyperglycemia, leukocytosis). Check parenteral access device frequently. ■ Monitor for S/S of fat overload syndrome. ■ Monitor severely undernourished patients for S/S of refeeding syndrome. ■ Monitor blood glucose levels and treat hyperglycemia to maintain optimum levels while infusing parenteral nutrition. Insulin may be administered or adjusted to maintain optimum blood glucose levels during parenteral nutrition administration. ■ Monitor for thrombophlebitis, which may manifest as erythema, pain, tenderness, or a palpable cord. ■ Monitor for S/S of hepatobiliary disorders (e.g., elevated LFTs/ammonia, jaundice). ■ Monitor overall energy intake and other sources of lipid and dextrose, as well as drugs that may interfere with lipid and dextrose metabolism.

Patient Education:

Report S/S of hyperglycemia, hypersensitivity reaction (e.g., bronchospasm, itching, rash, wheezing), hypoglycemia, infection (e.g., fever), nausea, vomiting, or fluid retention. ■ Periodic laboratory tests and routine follow-up with health care provider required. ■ Report any changes in prescription or nonprescription medications and supplements.

Maternal/Child:

Category C: use during pregnancy only if clearly needed. Parenteral nutrition should be considered in cases of severe maternal malnutrition in which nutritional requirements cannot be fulfilled by enteral route because of the risks to the fetus associated with severe malnutrition, such as preterm delivery, low birth weight, intrauterine growth restriction, congenital malformations, and perinatal mortality. ■ Use caution during breast-feeding. ■ Safety and effectiveness in pediatric patients have not been established. Deaths in preterm infants after infusion of IV lipid emulsions have been reported. Autopsy findings included intravascular fat accumulation in the lungs. Preterm infants and low-birth-weight infants have poor clearance of IV lipid emulsion and increased free fatty acid plasma levels following lipid emulsion infusion. ■ Not recommended for use in pediatric patients under 2 years of age, including preterm infants, because the fixed content of the formulation does not meet the nutritional requirements of this age-group.

Elderly:

Differences in response between the elderly and younger patients have not been identified. Dose selection should be cautious; see Dose Adjustment.

DRUG/LAB INTERACTIONS

High levels of lipid in plasma may interfere with **some laboratory blood tests,** such as hemoglobin, triglycerides, bilirubin, LDH, and oxygen saturation, if blood is sampled before lipid has been cleared from the bloodstream. Lipids are normally cleared after a lipid-free interval of 5 to 6 hours in most patients. ■ Kabiven and Perikabiven contain vitamin K, which can reverse coumarin and coumarin derivatives, including **warfarin**. Monitor laboratory parameters for anticoagulant activity in patients who are taking both Kabiven or Perikabiven and warfarin.

SIDE EFFECTS

Kabiven:

The most common adverse reactions are decreased hemoglobin, decreased total protein, fever, hypertension, hypokalemia, increased gamma glutamyltransferase (GGT), nausea, vomiting. Less frequently reported reactions include decreased blood calcium, hyperglycemia, increased blood alkaline phosphatase, prolonged PT, pruritus, tachycardia.

Perikabiven:

The most common adverse reactions are fever, hyperglycemia, hypokalemia, and increased blood triglycerides. Less frequently reported reactions include hypoalbuminemia, increased alanine aminotransferase (ALT), increased blood alkaline phosphatase, increased BUN, increased C-reactive protein, increased GGT, nausea, phlebitis, and pruritus. A number of other reactions occurred in 1% or fewer of patients. See Precautions for serious adverse reactions that have been reported with Kabiven or

Perikabiven.

Post-Marketing:

Kabiven:

Cholestasis, hypersensitivity reaction (including anaphylaxis), infection, subependymal hemorrhage.

Perikabiven:

Abdominal distension, abdominal pain, chest tightness, cholestasis, flushed face, infection.

ANTIDOTE

Notify the physician immediately of any adverse symptoms. Stop infusion for severely elevated electrolyte levels or triglyceride levels above 400 mg/dL. Monitor electrolytes and triglycerides. Re-initiate infusion at a reduced rate when laboratory values are within normal limits. Consider discontinuation or dosage reduction in patients who develop liver test abnormalities. Stop infusion immediately at the first sign of a hypersensitivity reaction and treat as indicated (antihistamines, epinephrine, corticosteroids, airway management, oxygen). Resuscitate as necessary. In the event of an overdose, fat overload syndrome may result. Stop infusion and allow lipids to clear from serum. Effects are usually reversible after the lipid infusion is stopped. The lipid administered and the fatty acids produced are not dialyzable.

PROTEIN (AMINO ACID) PRODUCTS

(**PROH**-teen [ah-**MEE**-noh **AS**-id] **PROD**-ucks)
Aminess 5.2% with histadine ■ Aminosyn 3.5%, 3.5% M, 5%, 7%, 8.5%, 10% ■ Aminosyn 7%, 8.5%, and 10% with electrolytes ■ Aminosyn (pH 6) 8.5% and 10% ■ Aminosyn HBC 7% ■ Aminosyn HF 8% ■ Aminosyn II 7%, 8.5%, 10%, and 15% ■ Aminosyn II 7%, 8.5%, and 10% with electrolytes ■ Aminosyn II 3.5% in D5 or D25 ■ Aminosyn II 5% in D25 ■ Aminosyn II 4.25% in D10, D20, and D25 ■ Aminosyn II 3.5% M and 4.5% M in D10 ■ Aminosyn II 3.5% in D25 with electrolytes and calcium ■ Aminosyn II 4.25% in D20, D25 with electrolytes and calcium ■ Aminosyn PF 7% and 10% ■ Aminosyn RF 5.2% ■ 4% Branch Amin ■ Clinimix 2.75% (sulfite free [SF]) in D5, D10, and D25 ■ Clinimix 4.25% (SF) in D5, D10, D20, and D25 ■ Clinimix 5% (SF) in D10, D15, D20, D25, and D35 ■ Clinimix E 2.75% (SF) in D5, D10, D25 with electrolytes and calcium ■ Clinimix E 4.25% (SF) in D5, D10, D20, and D25 with electrolytes and calcium ■ Clinimix E 5% (SF) in D10, D15, D20, D25, and D35 with electrolytes and calcium ■ Clinisol 15% (SF) ■ Crystalline amino acid infusions ■ FreAmine HBC 6.9% ■ FreAmine III 8.5%, 10%, and 3% and 8.5% with electrolytes ■ HepatAmine 8% ■ Hepatasol 8% ■ Hyperalimentation ■ NephrAmine 5.4% ■ Novamine 11.4% and 15% ■ Premasol 6% and 10% ■ ProcalAmine ■ ProSol 20% (sulfite free) ■ Protein hydrolysates ■ RenAmin without

electrolytes ■ Total parenteral nutrition ■ Travasol 2.75% and 4.25% in D5, D10, and D25 ■ Travasol 4.25% (SF) in D25 with electrolytes ■ Travasol 5.5%, 8.5%, and 10% without electrolytes ■ Travasol 3.5%, 5.5%, and 8.5% with electrolytes ■ Travasol (SF) 3.5%, 5.5%, and 8.5% with electrolytes ■ TrophAmine 6% and 10%
Nutritional therapy
pH 5 to 7

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Recommended dose:

0.5 to 2 Gm/kg of body weight/24 hr. Actual dose will depend on several factors, including daily protein and calorie requirements, disease state, physical condition, weight, and patient's metabolic and clinical response. Protein amino acid products are available in general, renal failure, hepatic failure/encephalopathy, and metabolic stress formulations. See Precautions/Monitor.

PEDIATRIC DOSE

Consult pharmacist; not all products are approved for use in pediatric patients. Amino acid formulations developed specifically for nutritional support of infants and other pediatric patients are available (e.g., Aminosyn P/F sulfite free). Amino acid concentrations greater than 2.5% are too concentrated for infants; older pediatric patients may tolerate concentrations up to 5%. See Maternal/Child.

Actual dose and total volume will depend on several factors including age, protein requirements, disease state, physical condition, renal function, and weight. Infants and children require different percentages of all components. The primary source of calories is dextrose. IV fat emulsion may be used to supplement energy intake. Kcal requirements may be increased in malnutrition or stress.

One source indicates that normal energy requirements vary according to age and suggests the following:

1 to 7 years:

75 to 90 kcal/kg/day

7 to 12 years:

60 to 75 kcal/kg/day

12 to 18 years:

30 to 60 kcal/kg/day

Another source suggests a Gm/kg/day dose based on age:

1 to 3 years:

2 to 2.5 Gm/kg/day

4 to 12 years:

2 Gm/kg/day

13 to 15 years:

1.7 Gm/kg/day

16 years and older:

1.5 Gm/kg/day

A third source suggests a Gm/kg/day dose based on age and condition:

Pediatric patients from neonates to 10 years of age:

Unstressed and over 1 year of age:

1 to 1.2 Gm/kg/day

Unstressed and 1 year of age or under:

1.6 to 2.2 Gm/kg/day

Low stress or maintenance:

2 to 2.5 Gm/kg/day

Low-stress anabolism:

2.5 to 3 Gm/kg/day

Critically ill or severe burn injury:

2.5 to 3.5 Gm/kg/day

DILUTION

Dilute under strict aseptic techniques according to manufacturer’s specific instructions. Some solutions are very concentrated; are for compounding only, not for direct infusion. Check label for aluminum content; see Precautions. Most commonly mixed with dextrose (nonprotein calorie source), electrolytes, vitamins, and trace elements to provide total parenteral nutrition (TPN) or peripheral parenteral nutrition (PPN). Intravenous lipids, providing a second nonprotein calorie source and a source of essential fatty acids, may be mixed with the dextrose/amino acid solution or run simultaneously. Use promptly after mixing; laminar flow hood preferred; refrigerate briefly if necessary, and discard any unused portion. Use only clear solutions; observe against adequate light for particulate matter or evidence of container damage.

Filters:

Use of in-line filters is recommended. Use of a 0.22-micron in-line microfilter for dextrose and amino acids. Use a 1.2-micron in-line microfilter for solutions with lipids (3 in 1). A precipitate is very difficult to detect in solutions that contain lipids.

Storage:

Store unopened protein amino acid solutions at 20° to 25° C (68° to 77° F). Protect from freezing or excessive heat. Protect from light until use. Manufacturer recommends refrigeration after any additives (e.g., IV lipids, electrolytes, minerals) are added. Some preparations can be refrigerated for only short periods, preferably no more than 24 hours. When prepared for home use, some preparations have been refrigerated for up to 14 days (dextrose and amino acids) or up to 7 days with lipids added. Leave vitamins (e.g., M.V.I.) out until time of administration. Consult pharmacist. Discard any single bottle after 24 hours at CRT.

COMPATIBILITY

Most **incompatibilities** relate to the preparation (chloride as opposed to phosphate), amount of medication added, other additives present, and thoroughness of mixing. Consult with the pharmacist before mixing any drugs in protein (amino acid) products. Many TPN solutions contain some phosphate. The addition of calcium salts may cause a precipitate. These additives must be mixed by the pharmacist. Specific amounts, calculations, temperature (precipitate forms more readily at room temperature), and order of dilution are required. Do not administer solutions containing calcium through the same administration set as blood; coagulation may occur.

Manufacturers suggest that only required nutritional products should be added, but H_2 receptors, insulin, and heparin are frequently added to selected products. Other drugs may be **compatible** for specific lengths of time. Mix thoroughly. Do not store.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Begin parenteral nutrition at 0.5 to 2 mL/min and increase gradually as tolerated until the target rate is reached. The rate of a nutrient infusion is governed by the protein requirement and by the patient's glucose tolerance. With the correct parenteral nutrition formulation, fluid, protein, and calorie requirements should be met at the target rate. ***Total daily dose should be evenly distributed over the 24-hour period. Maintain a constant drip rate.*** Use of infusion pump and microfilter (0.22 micron for dextrose and amino acids, 1.2 micron for solutions with lipids [3 in 1]) recommended. Precipitate very difficult to detect in solutions that contain lipids. There are specific situations (e.g., cyclic TPN primarily used in home care patients) where a daily dose is given over less than 24 hours. Range is from 10 to 14 hours. Usually administered overnight, allowing individuals requiring prolonged TPN to maintain their daytime activities.

Pediatric rate:

Usually begin with a one-half strength nutritional solution at 60 to 70 mL/kg/day. May be gradually increased over 48 hours until full strength and increased to 125 to 150 mL/kg/day. See all comments under Pediatric Dose, Rate of Administration/Adult, and Maternal/Child.

ACTIONS

Supplies essential and nonessential amino acids and calories with the intent of promoting protein production (anabolism) and preventing protein breakdown (catabolism). Promotes wound healing, and acts as a buffer in intracellular and extracellular body fluids. Various brands supply additional calories with alcohol, fructose, or glucose. These additional calories permit available protein to be used for repair of tissue in addition to meeting basic caloric needs.

INDICATIONS AND USES

To prevent nitrogen loss or to reverse negative nitrogen balance in severe illness when oral alimentation is not practical for prolonged periods; when normal GI absorption is impaired; when metabolic requirements for protein and calories are substantially increased, as with extensive burns; or when morbidity and mortality may be reduced by replacing amino acids lost from tissue breakdown, thereby preserving tissue reserves, as in acute renal failure.

CONTRAINDICATIONS

Hypersensitivity to any component, hepatic coma, or metabolic disorders involving impaired nitrogen utilization. Some manufacturers also list acidosis, anuria, azotemia, decreased circulating blood volume, severe liver disease, and metabolic disorders with impaired amino acid metabolization. ■ Solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Catheter insertion for administration of central parenteral nutrition is a sterile surgical procedure (must be a large vein [subclavian or superior vena cava preferred]; 50% glucose is a sclerosing solution). ■ Peripheral veins are suitable for specific products (peripheral parenteral nutrition) when amino acid products are diluted with 2.5%, 5%, or 10% dextrose. ■ Safe and effective use of central venous nutrition requires knowledge of nutrition as well as clinical expertise in recognition and treatment of the complications that can occur. Frequent clinical evaluation and laboratory determinations are necessary for proper monitoring of central venous nutrition; see Monitor. ■ Amino acids given without carbohydrates may cause ketone accumulation. ■ Use caution in impaired hepatic function; may cause serum amino acid imbalances, metabolic alkalosis, prerenal azotemia, hyperammonemia, stupor, and coma. ■ Use caution in impaired renal function; may further increase BUN. ■ Concentrated dextrose solutions, if administered too rapidly, may result in significant hyperglycemia and possible hyperosmolar syndrome characterized by mental confusion and loss of consciousness. ■ Fatty infiltration of the liver, acute respiratory failure, and difficulty in weaning hypermetabolic patients from the respirator may be caused by excessive carbohydrate calories. ■ Avoid circulatory overload, particularly in patients with cardiac insufficiency. ■ Solutions containing electrolytes should be used with caution in selected patients (e.g., sodium ions, use caution in patients with CHF, renal insufficiency, and clinical states with edema with sodium retention; potassium ions, use caution in patients with hyperkalemia, renal insufficiency, and conditions with potassium retention; acetate ions from inorganic salts, use caution in patients with metabolic or respiratory alkalosis). ■ Some solutions may contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive greater than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. ■ Some solutions may contain sulfites; use caution in patients allergic to sulfites. ■ Essential fatty acid deficiency has been observed in patients on long-term TPN (more than 5 days). The use of fat emulsion to provide 4% to 10% of total caloric intake as linoleic acid may help to prevent this deficiency.

Monitor:

Specific baseline studies required before administration: CBC, platelet count, PT, BUN, SCr, electrolytes, glucose, triglycerides, cholesterol, albumin, bilirubin, liver function tests (e.g., AST, ALT, LDH), acid-base balance, fluid balance, weight, body length and head circumference (in infants), and immunocompetence. Frequent clinical evaluation and lab tests are indicated during therapy. ■ Monitor intake and output and weight. More frequent monitoring of serum glucose and additional insulin may be indicated in patients with diabetes. After stabilization, measurement of urine glucose and ketones every 8 hours is suggested. ■ Follow a strict, regular aseptic routine to care for insertion site. ■ Single-port central venous catheters to be used only for the nutritional regimen. Do not draw blood samples, transfuse blood, or administer other medications. Pseudoagglutination and thrombosis can occur, risk of contamination is great, and validity of results is compromised. Multiple-port central venous catheters may be used for these additional procedures. Observe specific protocols. ■ Monitor BUN frequently. Discontinue infusion if BUN exceeds normal postprandial limits and continues to rise. ■ Blood ammonia levels important, especially in infants. ■ Check frequently for any signs of extravasation. ■ Observe for any signs of infection. ■ Additional insulin coverage may be required, especially when dosage is increased too rapidly or with maximum doses. ■ To prevent rebound hypoglycemia, may need to decrease rate gradually over 2 to 6 hours. ■ Discard any single bottle after 24 hours. Replace administration set every 24 to 72 hours depending on formulation and facility-specific policies. ■ See Precautions.

Maternal/Child:

Category C: use during pregnancy only if clearly needed. ■ Safety for use during breast-feeding not established; effects unknown. Use caution; has potential for adverse effects in nursing infants (e.g., hyperammonemia). ■ Use with caution in pediatric patients with renal failure. ■ Monitor neonates and very small infants carefully to maintain fluid and electrolyte balance, including monitoring of blood glucose. ■ Use hypertonic dextrose (component of parenteral nutrition) with extreme caution in low-birth-weight or septic infants. May cause hyperglycemia, hypoglycemia, or increased serum osmolality with possible intracerebral hemorrhage. Monitor serum glucose frequently. Solutions should not exceed 718 mOsm/L. ■ Amino acid concentrations greater than 2.5% are too concentrated for infants. ■ Hyperammonemia is of particular significance in infants. Can cause mental retardation; measure blood ammonia frequently.

Elderly:

Differences in responses between elderly and younger patients have not been identified; however, incidence of fluid overload and electrolyte imbalance may be increased. Monitor closely. ■ Lower-end initial doses may be appropriate in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy. Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

Tetracycline may reduce protein-sparing effects. ■ **Magnesium-containing solutions** may have an additive CNS depressive effect with barbiturates, hypnotics, narcotics, or systemic anesthetics; dose adjustment of these agents may be indicated.

SIDE EFFECTS

Abdominal pains, anaphylaxis, bone demineralization, changes in levels of consciousness, convulsions, dehydration, edema at the site of injection, electrolyte imbalances, glycosuria, hyperammonemia, hyperglycemia, hyperpyrexia, hypertension, metabolic acidosis and/or alkalosis, osmotic dehydration, phlebitis and thrombosis, pulmonary edema, rebound hypoglycemia, septicemia, vasodilation, vomiting, weakness.

ANTIDOTE

Notify the physician of all side effects. An alternate brand may cause fewer problems, or amounts of glucose or additives may be adjusted to correct the problem. Many of the side effects listed will respond to a reduced rate. Some will require catheter insertion at a new site. Treat symptomatically and resuscitate as necessary. Stop infusion immediately for any signs of acute respiratory distress. May represent pulmonary embolus or interstitial pneumonitis, which may be caused by a precipitate of electrolytes (e.g., calcium and phosphates) in the solution.

PROTEIN C CONCENTRATE (HUMAN)

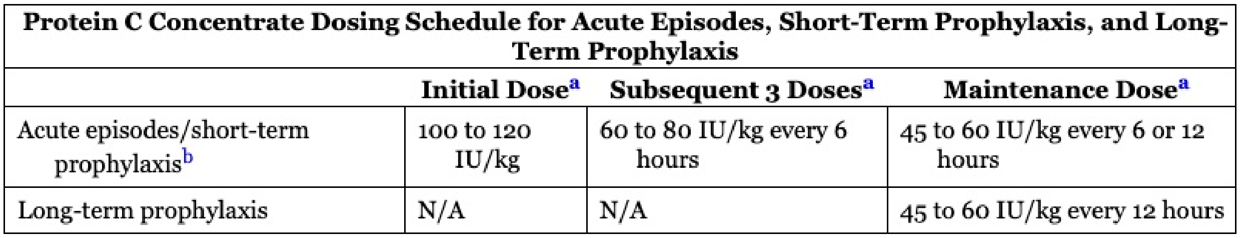
(**PROH**-teen C **KON**-sen-trayt)
Ceprotin
Anticoagulant
Antithrombotic
pH 6.7 to 7.3

USUAL DOSE (International units [IU])

Pretreatment:

Baseline studies indicated; see Monitor.

Dose, administration frequency, and duration of treatment depend on the severity of the protein C deficiency, the patient’s age, the clinical condition of the patient, and the patient's plasma level of protein C. Initiate therapy as directed in the chart below and adjust the dosage regimen according to the pharmacokinetic profile for each patient. See Dose Adjustments and Monitor.



Protein C Concentrate Dosing Schedule for Acute Episodes, Short-Term Prophylaxis, and Long-Term Prophylaxis			
	Initial Dose[a]	**Subsequent 3 Doses**[a]	**Maintenance Dose**[a]
Acute episodes/short-term prophylaxis[b]	100 to 120 IU/kg	60 to 80 IU/kg every 6 hours	45 to 60 IU/kg every 6 or 12 hours
Long-term prophylaxis	N/A	N/A	45 to 60 IU/kg every 12 hours

[a] Dose regimen should be adjusted according to the pharmacokinetic profile for each individual patient.

[b] Continue therapy until the desired anticoagulation is achieved.

PEDIATRIC AND NEONATAL DOSE

See Usual Dose and Maternal/Child.

DOSE ADJUSTMENTS

For treatment of acute episodes or with short-term prophylaxis, adjust dose according to the pharmacokinetic profile of the patient. Adjust to maintain a target peak protein C activity of 100%. After resolution of the acute episode, continue patient on the same dose to maintain a trough protein C activity above 25% for the duration of treatment. ■ Higher peak protein C activity levels may be required for situations in which there is an increased risk of thrombosis (e.g., infection, surgical intervention, trauma). Maintaining trough protein C activity levels above 25% is recommended. ■ Use in renal and hepatic impairment has not been studied. See Precautions.

DILUTION (International units [IU])

Available in single-dose vials that contain 500 or 1,000 international units (IU) of protein C. Reconstitute the 500-IU vial with 5 mL of SWFI and the 1,000-IU vial with 10 mL of SWFI to provide a single dose of human protein C at a concentration of 100 IU/mL. Vials also contain human albumin, trisodium citrate dihydrate, and sodium chloride as excipients. Bring the vials of protein C and SWFI (supplied diluent) to room temperature. Remove tops of vials and cleanse stoppers. Insert one end of the manufacturer-supplied double-ended transfer needle through the center of the diluent vial stopper. Invert the diluent vial and insert the free end of the double-ended transfer needle into the protein C vial. The vacuum in the vial should pull in the diluent. If a vacuum is not present, do not use the vial. Remove the double-ended transfer needle from the diluent vial, then from the protein C vial. Gently swirl the protein C vial until the powder is completely dissolved. The powder must be completely dissolved to prevent active materials from being removed by the filter needle during infusion. Solution should be colorless to slightly yellowish and clear to slightly opalescent. Attach manufacturer-supplied filter needle to a disposable syringe. Withdraw plunger to admit air into the syringe and inject air into the protein C vial. Withdraw reconstituted solution from the vial into the syringe. Remove the filter needle and attach a suitable needle or infusion set for administration. The filter needle is intended to filter the contents of a single vial of protein C.

Filters:

Filtering required; see Dilution.

Storage:

Refrigerate unopened vials in original carton at 2° to 8° C (36° to 46° F); protect from light. Shelf life is 3 years. Do not use beyond expiration date. Do not freeze. Administer reconstituted product within 3 hours of reconstitution. Single-dose vial; discard any unused product after entry into vial.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer as an infusion.

Adults and pediatric patients over 10 kg:

Maximum rate 2 mL/min.

Pediatric patients less than 10 kg:

Maximum rate 0.2 mL/kg/min.

ACTIONS

A precursor of the vitamin K–dependent anticoagulant glycoprotein (serine protease) that is synthesized in the liver. Manufactured from human plasma. Numerous processes are used during manufacturing to minimize the risk for viral transmission; see Precautions. Protein C is converted to activated protein C (APC), a serine protease with potent anticoagulant effects. APC exerts its effect by inactivation of the activated forms of factors V and VIII, which leads to a decrease in thrombin formation. APC also has been shown to have profibrinolytic effects. A complete absence of protein C is not compatible with life. A severe deficiency of this protein leads to unchecked coagulation activation, resulting in thrombin generation and intravascular clot formation and thrombosis. An increase in plasma levels of protein C can be seen within ½ hour after administration of protein C concentrate. Replacement of protein C in protein C–deficient patients is expected to control or, if given prophylactically, prevent thrombotic complications. In clinical studies, patients with severe congenital protein C deficiency were treated more effectively with protein C concentrate than those treated with modalities such as fresh frozen plasma or conventional anticoagulants. Half-life ranges from 4.9 to 14.7 hours, with a median of 9.8 hours. In patients with acute thrombosis, purpura fulminans, and skin necrosis, both the half-life and the increase in protein C plasma level may be reduced.

INDICATIONS AND USES

Prevention and treatment of venous thrombosis and purpura fulminans in patients with severe congenital protein C deficiency. A replacement therapy for pediatric and adult patients.

CONTRAINDICATIONS

None known.

PRECAUTIONS

Initiate treatment under the supervision of a physician experienced in replacement therapy with coagulation factors/inhibitors and in a facility where monitoring of protein C activity is available. ■ Half-life of protein C concentrate may be shortened in certain clinical conditions such as acute thrombosis, purpura fulminans, and skin necrosis. Patients treated during the acute phase of their disease may display much lower increases in protein C activity. ■ May contain trace amounts of mouse protein and heparin due to the manufacturing process. Hypersensitivity reactions are possible; see Monitor and Antidote. ■ Manufactured from pooled human plasma. Special screening and purification techniques are used to minimize the risk of transmitting infectious agents (e.g., hepatitis A, human parvovirus B19, Creutzfeldt-Jakob disease [CJD]), but transmission cannot be completely ruled out. Appropriate vaccination (hepatitis A and B) should be considered for patients receiving human-derived protein C. ■ Contains heparin. Discontinue if heparin-induced thrombocytopenia (HIT) is suspected; see Monitor. ■ Use with caution in patients who may be sensitive to a sodium load (e.g., patients with hypertension or CHF); see Monitor. ■ Patients being started on anticoagulant therapy with a vitamin K–antagonist anticoagulant (e.g., warfarin) may experience a transient hypercoagulable state before desired anticoagulation is reached. Patients may be at increased risk for warfarin-induced skin necrosis. Initiate warfarin therapy at a low dose and adjust incrementally as indicated by INR monitoring. Continue protein C replacement until stable anticoagulation with warfarin is reached. ■ Bleeding episodes have been reported. Simultaneous administration with alteplase (Activase, tPA) and/or anticoagulants (e.g., warfarin, heparin) may increase the risk of bleeding; see Drug Interactions. ■ Use with caution in patients with renal and/or hepatic impairment. Has not been studied.

Monitor:

Measure protein C activity using a chromogenic assay before and during treatment. ■ In the case of an acute thrombotic event, it is recommended that protein C activity measurements be obtained immediately before the next injection until the patient is stabilized. Once stabilized, continue monitoring to maintain the trough protein C level above 25%. ■ Coagulation parameters (e.g., INR/PT) should be monitored. However, a correlation between coagulation parameters and protein C activity levels has not been determined. ■ Discontinue therapy and check platelet count if heparin-induced thrombocytopenia is suspected. ■ Contains more than 200 mg of sodium. Monitor fluid and electrolyte status, especially in patients on a low-sodium diet and/or in patients with renal impairment. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, hives, hypotension, generalized itching, tightness of the chest, and/or wheezing).

Patient Education:

Manufactured from pooled human plasma. Risk of transmission of infectious agents cannot be ruled out. Discuss risk versus benefit of therapy with physician. ■ Review vaccination status with physician. Vaccination against hepatitis A and B should be considered. ■ Contains sodium. ■ Report S/S of hypersensitivity reaction immediately (e.g., hives, generalized itching, tightness of the chest, wheezing). ■ Consultation with a physician is required if abdominal pain, chills, drowsiness, fever, jaundice, nausea and vomiting, prolonged poor appetite, runny nose, tiredness, or dark urine occurs.

Maternal/Child:

Category C: safety for use in pregnancy and lactation has not been established. ■ Has been used in patients as young as 2 days of age. ■ Pharmacokinetics in the very young may differ from that of older pediatric patients and adults. Systemic exposure (C_{max} and AUC) may be reduced due to a faster clearance, larger volume of distribution, and/or shorter half-life. Doses must be individualized based on protein C activity levels; see Dose Adjustments.

Elderly:

Specific differences in safety and efficacy have not been identified.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Simultaneous use with **alteplase** (Activase, tPA) and **anticoagulants** (e.g., warfarin, heparin) may increase the risk of bleeding. ■ Patients being started on anticoagulant therapy with a **vitamin K–antagonist anticoagulant** (e.g., warfarin) may experience a transient hypercoagulable state before desired anticoagulation is reached; see Precautions.

SIDE EFFECTS

The most commonly reported side effects are itching, light-headedness, and rash.

Post-Marketing:

Fever, hemothorax, hyperhidrosis, hypotension, and restlessness.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Discontinue protein C concentrate for any serious reaction (e.g., HIT, hypersensitivity). Treat hypersensitivity reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Resuscitate as necessary.

PROTHROMBIN COMPLEX CONCENTRATE (HUMAN) BBW

(**PRO**-throm-bin **KOM**-plex **KAN**-sen-trayt [**HUE**-man])
Kcentra
Antihemorrhagic

USUAL DOSE (International Units [IU])

Pretreatment:

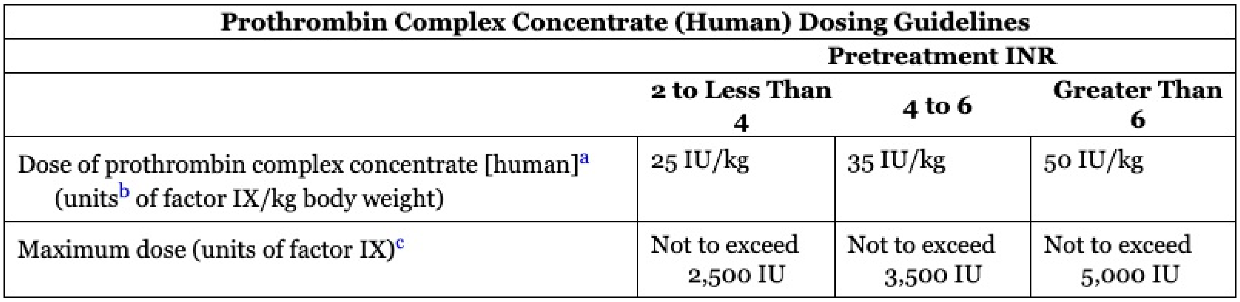
Dosing should be individualized based on the patient’s baseline International Normalized Ratio (INR) value and body weight.

Vitamin K:

Administer vitamin K (phytonadione) concurrently to maintain vitamin K–dependent factor levels once the effects of the prothrombin complex concentrate (human) have diminished.

Prothrombin complex concentrate (human):

Coagulation factor levels may be unstable in patients with acute major bleeding who are receiving vitamin K. Obtain baseline INR (close to time of dosing). Using this INR and the patient’s weight, individualize dose as shown in the following chart.



Prothrombin Complex Concentrate (Human) Dosing Guidelines			
	Pretreatment INR		
	2 to Less Than 4	4 to 6	Greater Than 6
Dose of prothrombin complex concentrate [human][a] (units[b] of factor IX/kg body weight)	25 IU/kg	35 IU/kg	50 IU/kg
Maximum dose (units of factor IX)[c]	Not to exceed 2,500 IU	Not to exceed 3,500 IU	Not to exceed 5,000 IU

[a] Dose is based on body weight. Dose is also based on actual potency as stated on the carton, which will vary from 20 to 31 factor IX units/mL.

[b] Units refer to international units.

[c] Dose is based on body weight up to but not exceeding 100 kg. For patients weighing more than 100 kg, maximum dose should not be exceeded.

Example dosing calculation for an 80-kg patient with a baseline INR of 5:

$$35 \text{ units of Factor IX/kg} \times 80 \text{ kg} = 2{,}800 \text{ units of Factor IX required}$$

For a vial with an actual potency of 30 units/mL factor IX, 93 mL would be given:

$$2{,}800 \text{ units} \div 30 \text{ units/mL} = 93 \text{ mL}$$

Repeat dosing with prothrombin complex concentrate is not supported by clinical data and is not recommended.

DILUTION (International units [IU])

Available in a kit that contains 500 units of prothrombin complex concentrate in a single-use vial, a 20-mL vial of SWFI, a Mix2Vial filter transfer set, and an alcohol swab. The actual potency per vial of factors II, VII, IX, and X and of proteins C and S is stated on the carton (potency in IU is defined by factor IX content). When reconstituted, the final concentration of drug product in factor IX units will range from 20 to 31 units/mL (400 to 620 units/vial) depending on actual potency, which is listed on the carton. Nominal potency is 500 units per vial, which is approximately 25 units/mL after reconstitution. Record the lot number of the product in the patient's medical record when prothrombin complex concentrate is administered.

Begin the reconstitution process by bringing prothrombin complex concentrate and diluent vial to room temperature. Use of aseptic technique required. Remove vial tops and wipe stoppers with the alcohol swab. Open the Mix2Vial transfer set package, leaving transfer set in the clear package. Place ***diluent vial*** on a flat surface and hold vial tightly. Grip the Mix2Vial transfer set together with the clear package and push the plastic spike at the ***blue end of the transfer set*** firmly through the center of the diluent vial stopper. Carefully remove the clear package from the Mix2Vial transfer set. With the ***prothrombin complex concentrate vial*** firmly on a flat surface, invert the diluent vial with the transfer set attached and push the plastic spike of the ***transparent adapter*** firmly through the center of the stopper of the prothrombin complex concentrate vial. The diluent will automatically transfer into the prothrombin complex concentrate vial. With both vials still attached to the transfer set, gently swirl the prothrombin complex concentrate vial to ensure complete dissolution. ***Do not shake.*** Solution should be colorless, clear to slightly opalescent, and free from visible particles. With one hand, grasp the prothrombin complex concentrate side of the Mix2Vial transfer set, and with the other hand grasp the blue diluent side of the Mix2Vial transfer set, and unscrew the set into two pieces. Draw air into an empty, sterile syringe. While the prothrombin complex concentrate vial is upright, screw the syringe to the Mix2Vial transfer set. Inject air into the vial. While keeping the syringe plunger pressed, invert the system upside down and draw the concentrate into the syringe by pulling the plunger back slowly. Unscrew the syringe from the transfer set and attach to a suitable intravenous administration set. If the same patient is to receive more than one vial, contents of multiple vials may be pooled. Use a separate, unused Mix2Vial transfer set for each product vial.

Storage:

Store lyophilized powder in carton at 2° to 25° C (36° to 77° F); protect from light and freezing. Stable for 36 months from date of manufacture. Do not use beyond the expiration date on the carton and vial labels. Product must be used within 4 hours following reconstitution. Reconstituted product can be stored at 2° to 25° C. If cooled, the solution should be warmed to 20° to 25° C (68° to 77° F, approximate room temperature) before administration. Do not freeze reconstituted product. Discard partially used vials.

COMPATIBILITY

Manufacturer states, "Do not mix with other medicinal products; administer through a separate infusion line. No blood should enter the syringe, as there is a possibility of fibrin clot formation."

RATE OF ADMINISTRATION

Administer at room temperature at a rate of 0.12 mL/kg/min (approximately 3 units/kg/min), up to a maximum of 8.4 mL/min (approximately 210 units/min).

ACTIONS

A purified, heat-treated, nanofiltered, and lyophilized nonactivated four-factor prothrombin complex concentrate prepared from human U.S. Source Plasma. Contains the vitamin K–dependent coagulation factors II, VII, IX, and X (together known as the prothrombin complex) and the antithrombotic proteins C and S. Factor IX is the lead factor for the potency of the preparation. (Human antithrombin III, heparin and human albumin, sodium chloride, and sodium citrate are listed as excipients.) A dose-dependent acquired deficiency of the vitamin K–dependent coagulation factors occurs during vitamin K antagonist (VKA) treatment. Vitamin K antagonists exert anticoagulant effects by lowering both factor synthesis and function. Administration of prothrombin complex concentrate rapidly increases plasma levels of the vitamin K–dependent coagulation factors II, VII, IX, and X as well as the antithrombotic proteins C and S. In clinical trials, prothrombin complex concentrate restored the decreased vitamin K–dependent clotting factors significantly faster than plasma in patients on warfarin. A single dose of prothrombin complex concentrate produced a rapid and sustained increase in plasma levels of factors II, VII, IX, and X within 30 minutes posttreatment with 87% less volume than with plasma. In addition, infusion time with prothrombin complex concentrate was seven times faster than with plasma. In most subjects, prothrombin complex concentrate decreased INR to less than or equal to 1.3 within 30 minutes. The relationship between this or other INR values and clinical hemostasis in patients has not been established.

INDICATIONS AND USES

Indicated for the urgent reversal of acquired coagulation factor deficiency induced by vitamin K antagonists (e.g., warfarin) therapy in adult patients with acute major bleeding. Not indicated for urgent reversal of vitamin K antagonist anticoagulation in patients without acute major bleeding.

CONTRAINDICATIONS

Patients with known anaphylactic or severe systemic reactions to prothrombin complex concentrate or any of its components, including heparin; factors II, VII, IX, and X; proteins C and S; antithrombin III; and human albumin. ■ Patients with disseminated intravascular coagulation (DIC). ■ Patients with known heparin-induced thrombocytopenia (HIT). Prothrombin complex concentrate contains heparin.

PRECAUTIONS

For IV use only. ■ Hypersensitivity reactions have been reported. ■ Both fatal and nonfatal arterial and venous thromboembolic complications have been reported. Patients being treated with VKA therapy have underlying disease states that predispose them to thromboembolic events. The potential benefits of reversing VKA should be weighed against the potential risks of thromboembolic events, especially in patients with a history of a thromboembolic event. Resumption of anticoagulation should be carefully considered as soon as the risk of thromboembolic events outweighs the risk of acute bleeding. ■ Prothrombin complex concentrate has not been studied in subjects who have had a thromboembolic event, myocardial infarction, disseminated intravascular coagulation, cerebrovascular accident, transient ischemic attack, unstable angina pectoris, or severe peripheral vascular disease within the previous 3 months. Prothrombin complex concentrate may not be suitable in patients who have had a thromboembolic event in the previous 3 months. ■ Made from human blood and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, hepatitis C). Numerous steps in the manufacturing process are used to make the potential for transmission of infectious agents extremely remote. ■ Prothrombin complex concentrate has not been studied in patients with congenital factor deficiencies.

Monitor:

Monitor INR and clinical response during and after treatment. ■ Standard clinical assessments (e.g., VS, hemoglobin measurements, CT assessments relevant to the type of bleeding [e.g., GI, cerebral]) may be used to evaluate effective hemostasis. ■ Monitor for S/S of hypersensitivity reactions (e.g., angioedema, anxiety, bronchospasm, dyspnea, flushing, hypotension, nausea, pulmonary edema, tachycardia, urticaria, wheezing, vomiting). ■ Monitor for signs and symptoms of thromboembolic events (e.g., deep venous thrombosis, pulmonary embolism, stroke) during and after administration of prothrombin complex concentrate.

Patient Education:

Report any S/S of hypersensitivity promptly (e.g., hives, rash, tightness of chest, wheezing). ■ Report S/S of thrombosis (e.g., limb or abdominal swelling and/or pain, chest pain or pressure, shortness of breath, loss of sensation or motor power, altered consciousness, vision, or speech). ■ Prothrombin complex concentrate is made from human blood and may carry a remote risk of transmitting infectious agents. See Precautions.

Maternal/Child:

Category C: safety for use during pregnancy, labor and delivery, and during breast-feeding not established; use only if clearly indicated. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Response similar to other age-groups.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

The most common side effects observed were arthralgia, headache, hypotension, nausea, and vomiting. The most serious side effects were thromboembolic events, including deep vein thrombosis, pulmonary embolism, and stroke. Other side effects included abnormal breath sounds, chest pain, constipation, dyspnea, fluid overload, hypertension, hypokalemia, hypoxia, insomnia, intracranial hemorrhage, mental status changes, myocardial infarction, myocardial ischemia, pulmonary edema, respiratory distress, and tachycardia.

Post-Marketing:

Hypersensitivity or allergic reactions (e.g., angioedema, anxiety, bronchospasm, dyspnea, flushing, hypotension, nausea, pulmonary edema, tachycardia, urticaria, vomiting, wheezing) and thromboembolic complications (arterial thromboembolic events [arterial thrombosis, acute MI], venous thromboembolic events [pulmonary embolism and venous thrombosis], and DIC).

ANTIDOTE

Notify physician of any side effect. If a severe hypersensitivity or anaphylactic-type reaction occurs, immediately discontinue administration and institute appropriate treatment (e.g., oxygen, hydrocortisone, epinephrine, diphenhydramine, famotidine).

PYRIDOSTIGMINE BROMIDE

(peer-id-oh-**STIG**-meen **BRO**-myd)
Reginol
Cholinergic
(cholinesterase inhibitor)
Antidote
pH 5

USUAL DOSE

Muscle relaxant antagonist:

Atropine:

Give atropine first or simultaneously (see Monitor) and maintain ventilation. An equipotent dose of glycopyrrolate may be used in place of atropine.

Pyridostigmine:

0.1 to 0.25 mg/kg of body weight (usually 10 to 20 mg) as a single dose. Should be administered after spontaneous recovery of neuromuscular function has begun. Use of a peripheral nerve stimulator device recommended. Repeat doses are not recommended.

PEDIATRIC DOSE

Safety for use in pediatric patients not established; see Maternal/Child.

DOSE ADJUSTMENTS

Lower dose may be indicated in patients with impaired renal function. Titrate dose to desired effect.

DILUTION

May be given undiluted. Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set.

COMPATIBILITY

Unstable in alkaline solutions.

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Muscle relaxant antagonist:

5 mg or fraction thereof over 1 minute.

ACTIONS

An anticholinesterase muscle stimulant and antagonist of skeletal muscle relaxants. Inhibits the enzyme cholinesterase, allowing acetylcholine to accumulate at the myoneural junction. Restores normal transmission of nerve impulses and makes muscle contraction stronger and more prolonged. Onset of action is dose dependent. Full recovery usually occurs within 15 to 30 minutes in most patients. Has fewer side effects and longer duration of action than neostigmine. Cleared by metabolism and renal excretion.

INDICATIONS AND USES

Antagonist to nondepolarizing muscle relaxants (e.g., atracurium [Tracrium]).

CONTRAINDICATIONS

Known sensitivity to anticholinesterase agents; mechanical intestinal or urinary obstruction.

PRECAUTIONS

Administered by or under the direct supervision of clinicians familiar with its use. ■ Edrophonium (Tensilon) can differentiate between increased symptoms of myasthenia and cholinergic crisis. ■ Use caution in bronchial asthma and cardiac arrhythmias.

Monitor:

Administer atropine sulfate, 0.6 to 1.2 mg IV or glycopyrrolate, immediately before or simultaneously with pyridostigmine. ***Caution:*** atropine may mask symptoms of pyridostigmine overdose. Cholinergic crisis may result. ■ Observe patient continuously. Maintain a patent airway and use artificial ventilation as indicated until adequate spontaneous respiration is confirmed. ■ A peripheral nerve stimulator device can monitor reversal and minimize the possibility of excess dosing or inadequate reversal. ■ Epinephrine and atropine should always be available. ■ Action may be altered by dehydration, electrolyte imbalance, body temperatures, and acid-base balance; monitor closely.

Maternal/Child:

Category C: use in pregnancy only if benefits outweigh risks. ■ Discontinue breast-feeding. ■ May induce premature labor in pregnancy near term. Transient muscular weakness in swallowing, sucking, and breathing has been observed in neonates of myasthenic mothers. Confirm distinction between cholinergic and myasthenic crisis in neonate with edrophonium test. ■ Safety for use in pediatric patients not established. ■ Contains benzyl alcohol as a preservative; not recommended for use in infants.

Elderly:

Duration of antagonism of neuromuscular blockade prolonged.

DRUG/LAB INTERACTIONS

Potentiates **narcotic analgesics** (e.g., morphine, meperidine) **and succinylcholine** (Anectine). Neuromuscular block may be prolonged or resistance to reversal may occur with concurrent use of **anesthetics** (ether), **ganglionic blocking agents** (e.g., trimethaphan [Arfonad]), **aminoglycoside antibiotics** (e.g., kanamycin [Kantrex], gentamicin), **other antibiotics** including but not limited to bacitracin (Altracin), colistimethate (Coly-Mycin M), colistin (Coly-Mycin S), polymyxin B, tetracyclines (e.g., doxycycline). ■ Neuromuscular block may be prolonged by **corticosteroids, magnesium, and quinidine.** ■ Onset of action may be delayed by **4-aminopyridine.**

SIDE EFFECTS

Usually caused by overdose:

Abdominal cramps, anorexia, anxiety, bradycardia, cardiac arrhythmias and arrest, cholinergic crisis, cold moist skin, convulsions, diaphoresis, diarrhea, hypotension, increased bronchial secretions, increased lacrimation, increased peristalsis, increased salivation, miosis, muscle cramps, muscle weakness, nausea, pulmonary edema, respiratory paralysis with apnea, skin rash (bromide), thrombophlebitis, vomiting.

ANTIDOTE

Atropine sulfate. If side effects occur, discontinue the drug and notify the physician. Atropine sulfate in doses of 0.6 mg IV will counteract most side effects and may be repeated every 3 to 10 minutes. Endotracheal intubation or tracheostomy is considered prophylactic in anesthesia or crisis. Artificial ventilation, oxygen therapy, cardiac monitoring, adequate suctioning, and treatment of shock or convulsions must be instituted and maintained as necessary. Treat allergic reactions with epinephrine.

PYRIDOXINE HYDROCHLORIDE

(peer-ih-**DOX**-een hy-droh-**KLOR**-eyed)
Vitamin B_6
Nutritional supplement (vitamin)
Antidote
pH 2 to 3.8

USUAL DOSE

Pyridoxine dependency syndrome:

30 to 600 mg/day.

Drug-induced pyridoxine deficiency:

50 to 200 mg/day for 3 weeks. Follow with 25 to 100 mg/day as needed.

Prophylaxis or treatment of pyridoxine deficiency in patients receiving parenteral nutrition:

May be added to parenteral nutrition; dose will depend on patient condition.

INH poisoning (greater than 10 Gm) (unlabeled):

4 Gm IV followed by 1 Gm IM every 30 minutes. Total pyridoxine dose should equal ingested INH dose.

Cycloserine poisoning (unlabeled):

300 mg/day. Higher doses may be required.

Hydrazine poisoning (unlabeled):

25 mg/kg. Give one third of dose IM and remainder as a 3-hour infusion.

Gyrometra mushroom poisoning (unlabeled):

25 mg/kg over 15 to 30 minutes. Repeat as needed.

PEDIATRIC DOSE

See Maternal/Child.

Pyridoxine-dependent seizures:

10 to 100 mg.

DOSE ADJUSTMENTS

Removed by hemodialysis. Dialysis patients may require higher doses.

DILUTION

May be given by IV injection undiluted or added to most IV solutions and given as an infusion. See chart on inside back cover.

Storage:

Store below 40° C unless otherwise stated by manufacturer. Deteriorates in excessive heat; protect from heat and light.

COMPATIBILITY

Manufacturer lists as **incompatible** with alkaline solutions, iron salts, oxidizing solutions.

RATE OF ADMINISTRATION

50 mg or fraction thereof over 1 minute if given undiluted.

ACTIONS

Vitamin B_6 is water soluble. It is a coenzyme necessary for the metabolism of proteins, carbohydrates, and lipids. Involved in many reactions, including the conversion of tryptophan to nicotinamide and serotonin, breakdown to glucose-1-phosphate, synthesis of gamma aminobutyric acid (GABA) in the CNS (energy transformation in brain and nerve cells), and synthesis of heme. Metabolized by the liver and excreted in the urine.

INDICATIONS AND USES

Prophylaxis and treatment of pyridoxine deficiency. Deficiency may be due to inadequate diet, inborn error of metabolism, or concomitant drug use.

Unlabeled uses:

Treatment of INH, hydrazine, and cycloserine poisoning. Treatment of neurologic effects of Gyrometra mushroom poisoning. Nausea and vomiting associated with pregnancy.

CONTRAINDICATIONS

Known sensitivity to pyridoxine.

PRECAUTIONS

Used IV only when oral dosage not acceptable. ■ Deficiency can cause abnormal EEG. ■ Need for pyridoxine increases with amount of protein in diet. Chronic administration of large doses may cause adverse neurologic effects.

Maternal/Child:

Category A: requirements are increased in pregnancy and breast-feeding. Do not exceed RDA. ■ Large doses in utero can cause pyridoxine-dependency syndrome in newborn. ■ May inhibit breast-feeding. ■ Safety for use in pediatric patients not established.

DRUG/LAB INTERACTIONS

An antagonist to **levodopa.** Does not antagonize carbidopa/levodopa combination (Sinemet). ■ **Isoniazid** is a vitamin B_6 antagonist and will cause deficiency disease. ■ **Cycloserine, penicillamine, hydralazine, and oral contraceptives** may increase pyridoxine requirements. ■ May decrease **phenobarbital and phenytoin** (Dilantin) levels. ■ Excessive doses **may elevate AST.**

SIDE EFFECTS

Almost nonexistent; some slight flushing or feeling of warmth may occur. With larger doses, ataxia, low folic acid levels, paresthesias, somnolence, and withdrawal seizures in infants with high maternal doses may occur.

ANTIDOTE

No antidote is known or has been needed. Symptomatic treatment of side effects may be indicated.

---

[a] These indications are approved under accelerated approval based on tumor response rate and durability of response. Continued approval for these indications may be

contingent on verification and description of clinical benefit in the confirmatory trials.

[a] Seen as a manifestation of rapid IV administration and/or hyperkalemia.

ROMIDEPSIN

R

RASBURICASE BBW

(ras-**BYOUR**-ih-kase)
Elitek
Antihyperuricemic
Enzyme, urate-oxidase (recombinant)

USUAL DOSE

Pretreatment:

Prehydration and baseline studies required; see Monitor.

0.2 mg/kg as a single daily dose each day for up to 5 days. Dosing beyond 5 days and/or administration of more than one course of rasburicase is not recommended. Safety and effectiveness of other schedules have not been evaluated. Alternate unlabeled single- and multiple-dose regimens have been used; see literature.

PEDIATRIC DOSE

Same as adult dose; see Maternal/Child.

DOSE ADJUSTMENTS

No dose adjustments recommended.

DILUTION

Available in 1.5- and 7.5-mg single-dose vials with manufacturer-supplied diluent (SWFI and Poloxamer 188). Determine the vial size and/or number of vials needed to provide the calculated dose. Reconstitute each 1.5-mg vial with 1 mL of diluent and each 7.5-mg vial with 5 mL of diluent. Final concentration is 1.5 mg/mL. Mix by swirling gently. ***Do not shake.*** Withdraw the calculated dose of reconstituted solution and inject into an infusion bag containing the appropriate volume of NS to achieve a final total volume of 50 mL. (For example a 20-kg child would receive a dose of 4 mg [20 kg × 0.2 mg/kg = 4 mg]. Reconstitute 3 vials, each with 1 mL of the diluent provided. Withdraw 2.7 mL of reconstituted solution and add to an infusion bag containing 47.3 mL of NS.)

Filters:

No filter should be used during reconstitution or infusion of rasburicase.

Storage:

Refrigerate unopened lyophilized drug product and diluent. Do not freeze; protect from light. Both the reconstituted and diluted product may be stored for 24 hours if refrigerated. Discard any unused product.

COMPATIBILITY

Manufacturer states, “Should be infused through a different line than that used for the infusion of other concomitant medications. If use of a separate line is not possible, the line should be flushed with at least 15 mL of NS prior to and after infusion with rasburicase.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 minutes.

Do not administer as a bolus infusion. Do not filter infusion.

ACTIONS

A recombinant urate-oxidase enzyme produced by genetic engineering. Catalyzes enzymatic oxidation of uric acid into an inactive and soluble metabolite (allantoin). Onset of action is 4 hours. Mean terminal half-life is similar between pediatric and adult patients and ranges from 15.7 to 22.5 hours.

INDICATIONS AND USES

Initial management of plasma uric acid levels in pediatric and adult patients with leukemia, lymphoma, and solid tumor malignancies who are receiving anticancer therapy that is expected to result in tumor lysis and subsequent elevation of plasma uric acid.

Limitation of use:

Indicated only for a single course of treatment.

CONTRAINDICATIONS

Glucose-6-phosphate dehydrogenase (G6PD) deficiency. ■ History of anaphylaxis or severe hypersensitivity to rasburicase. ■ History of development of hemolytic reactions or methemoglobinemia with rasburicase.

PRECAUTIONS

May cause serious and fatal hypersensitivity reactions, including anaphylaxis. Reactions may occur at any time during treatment, including with the first dose; see Monitor and Antidote. ■ Has caused severe hemolytic reactions in patients with G6PD deficiency. It is recommended that patients at higher risk for G6PD deficiency (e.g., patients of African or Mediterranean descent) be screened for G6PD deficiency before starting rasburicase therapy. See Contraindications and Antidote. ■ Methemoglobinemia has been reported. Patients developed serious hypoxemia, requiring intervention. See Antidote. ■ As with all therapeutic proteins, there is the potential for immunogenicity. May elicit antibodies that inhibit the activity of rasburicase.

Monitor:

Monitor serum uric acid levels, electrolytes, and renal function before and during therapy. ■ Patients should be hydrated intravenously according to standard medical practice for the management of plasma uric acid in patients at risk for tumor lysis syndrome (TLS). ■ Observe for signs of TLS (e.g., hyperuricemia, hyperkalemia, hyperphosphatemia, and hypocalcemia). If untreated, may develop acute uric acid nephropathy, leading to renal failure. ■ Monitor for S/S of a hypersensitivity reaction (e.g., anaphylaxis, bronchospasm, chest pain and tightness, dyspnea, hypotension, hypoxia, shock, urticaria). ■ Screen patients at risk for hemolysis; see Contraindications and Precautions. Monitor for S/S of hemolysis (e.g., anemia, jaundice with increased indirect bilirubin and LDH, pallor, reduced haptoglobin). In studies, severe hemolytic reactions occurred within 2 to 4 days of the start of therapy. ■ Monitor for S/S of methemoglobinemia (e.g., cyanosis, dyspnea, headache, hypoxemia, lethargy, methemoglobin). ■ Will cause enzymatic degradation of uric acid within blood samples left at room temperature, resulting in falsely low uric acid levels. To ensure accurate measurement, blood must be collected into prechilled tubes containing heparin anticoagulant and immediately *immersed and maintained* in an ice water bath. Plasma samples must be prepared by centrifugation in a precooled centrifuge (4° C [39° F]). Plasma samples must be analyzed within 4 hours of sample collection.

Patient Education:

Report blood in urine, painful urination, or signs of a hypersensitivity reaction promptly. ■ See Maternal/Child.

Maternal/Child:

Based on animal studies, may cause fetal harm. Potential benefits must justify potential risks to fetus. ■ Breast-feeding is not recommended during treatment and for 2 weeks after the last dose. ■ Studied in pediatric patients from 1 month to 17 years of age. Pediatric patients under 2 years of age had a higher mean uric acid AUC and a lower rate of success at achieving normal uric acid concentrations by 48 hours than did older pediatric patients.

Elderly:

No overall differences in pharmacokinetics, safety, and effectiveness were observed between elderly and younger patients.

DRUG/LAB INTERACTIONS

Studies have not been conducted. ■ Will cause enzymatic degradation of uric acid within blood samples left at room temperature, resulting in **falsely low uric acid levels;** see Monitor.

SIDE EFFECTS

The most common adverse reactions are abdominal pain, anxiety, constipation, diarrhea, fever, headache, hypophosphatemia, increased ALT, nausea, peripheral edema, pharyngolaryngeal pain, and vomiting. Serious adverse reactions observed are hemolysis, hypersensitivity reactions (e.g., anaphylaxis, arthralgia, chest pain, dyspnea, hypotension, injection site irritation, peripheral edema, rash, urticaria), methemoglobinemia, and severe rash. Other observed reactions include abdominal and GI infections, acute renal failure, fluid overload, hyperbilirubinemia, hyperphosphatemia, ischemic coronary artery disorders, mucositis, pulmonary hemorrhage, rash, respiratory distress/failure, sepsis, and supraventricular arrhythmias.

Post-Marketing:

Anaphylaxis with potential fatal outcome, convulsions, muscle contractions (involuntary).

ANTIDOTE

Notify physician of all side effects. Should be immediately and permanently discontinued in patients who experience severe hypersensitivity reactions, hemolysis, or methemoglobinemia. Do not rechallenge. Treat anaphylaxis with epinephrine, corticosteroids (e.g., dexamethasone), oxygen, and antihistamines (diphenhydramine). Hemolysis or methemoglobinemia may require transfusion support. Methylene blue may be required for treatment of methemoglobinemia. There is no specific antidote. Resuscitate as indicated.

RAVULIZUMAB-cwvz BBW

(**RAV**-ue-**LIZ**-ue-mab)
Ultomiris
Monoclonal antibody
pH 7

USUAL DOSE

Pretreatment:

Vaccinate patients for meningococcal disease according to current Advisory Committee on Immunization Practices (ACIP) recommendations for meningococcal vaccination in patients with complement deficiencies.

Premedication:

Provide 2 weeks of antibacterial drug prophylaxis to patients if ravulizumab-cwvz must be initiated immediately and vaccines are administered less than 2 weeks before starting ravulizumab-cwvz therapy.

Paroxysmal nocturnal hemoglobinuria (PNH):

Weight-based dosing for adults weighing 40 kg or greater consists of a loading dose followed 2 weeks later by a maintenance dose. Repeat maintenance doses every 8 weeks. Administer doses based on body weight as outlined in the following chart.

Ravulizumab-cwvz Weight-Based Dosing Regimen (PNH)

Body Weight Range (kg)	Loading Dose (mg)	Maintenance Dose (mg)	
≥40 to <60 kg	2,400 mg	3,000 mg	Every 8 weeks
≥60 kg to <100 kg	2,700 mg	3,300 mg	
≥100 kg	3,000 mg	3,600 mg	

Atypical hemolytic uremic syndrome (aHUS):

Weight-based dosing for adult and pediatric patients 1 month of age and older weighing 5 kg or greater consists of a loading dose followed 2 weeks later by a maintenance dose. Repeat maintenance doses every 4 or 8 weeks based on body weight as outlined in the following chart.

Ravulizumab-cwvz Weight-Based Dosing Regimen (aHUS)

Body Weight Range (kg)	Loading Dose (mg)	Maintenance Dose (mg) and Dosing Interval	
≥5 to <10 kg	600 mg	300 mg	Every 4 weeks
≥10 to <20 kg	600 mg	600 mg	
≥20 to <30 kg	900 mg	2,100 mg	Every 8 weeks
≥30 to <40 kg	1,200 mg	2,700 mg	
≥40 to <60 kg	2,400 mg	3,000 mg	
≥60 to <100 kg	2,700 mg	3,300 mg	
≥100 kg	3,000 mg	3,600 mg	

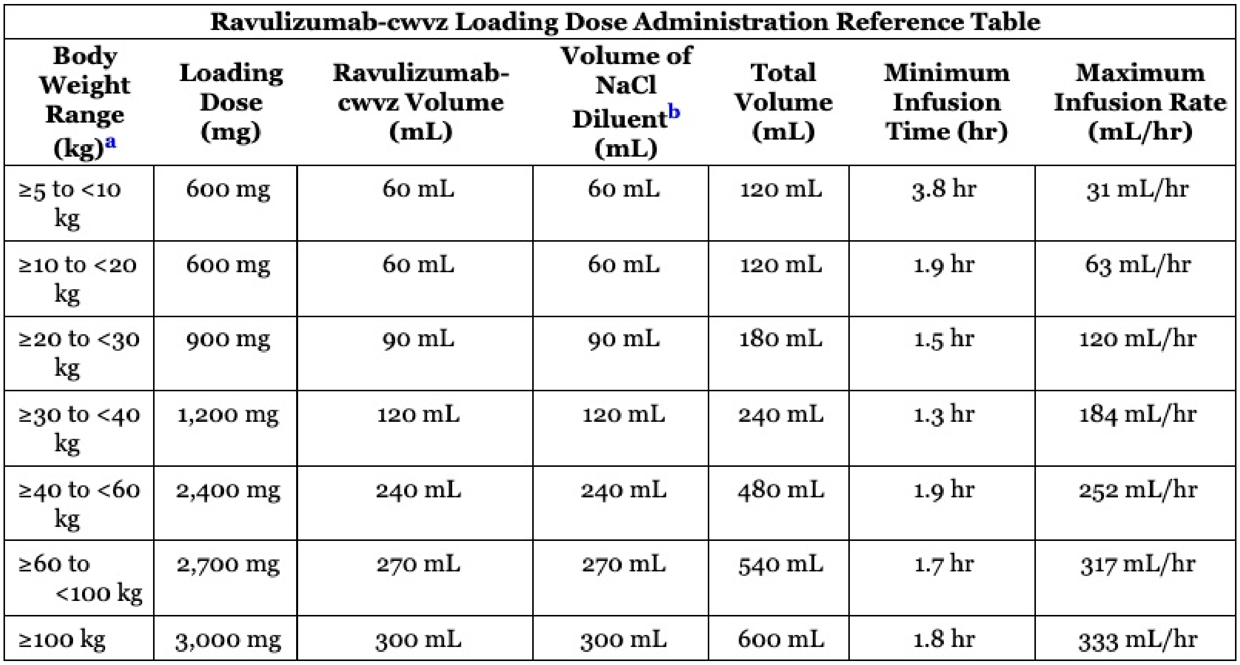
For either indication, the dosing schedule is allowed to occasionally vary within 7 days of the scheduled infusion day (except for the first maintenance dose), but the subsequent dose should be administered according to the original schedule. For patients switching from eculizumab to ravulizumab-cwvz, administer the loading dose of ravulizumab-cwvz 2 weeks after the last eculizumab infusion, and then administer maintenance doses once every 8 weeks or every 4 weeks (depending on body weight) starting 2 weeks after loading dose administration.

DOSE ADJUSTMENTS

Age (18 to 83 years), sex, race, hepatic impairment, or any degree of renal impairment do not appear to influence the pharmacokinetics of ravulizumab-cwvz. ■ Administration of PE/PI (plasmapheresis or plasma exchange, or fresh frozen plasma infusion) may reduce ravulizumab-cwvz serum levels. There is no experience with administration of supplemental doses of ravulizumab-cwvz.

DILUTION

Available in 300 mg/30 mL (10 mg/mL) single-dose vials. A clear to translucent, slight whitish color solution. The number of vials to be diluted is determined based on the individual patient's weight and the prescribed dose. Withdraw the calculated volume of ravulizumab-cwvz from the appropriate number of vials and dilute in an infusion bag using NS to a final concentration of 5 mg/mL. Mix gently. Do not shake. ***Protect from light. Do not freeze.*** Refer to the following administration reference charts. Allow the diluted solution to reach room temperature before infusion. Do not use an artificial heat source (e.g., microwave). Contains no preservatives. Administer the prepared solution immediately after preparation.

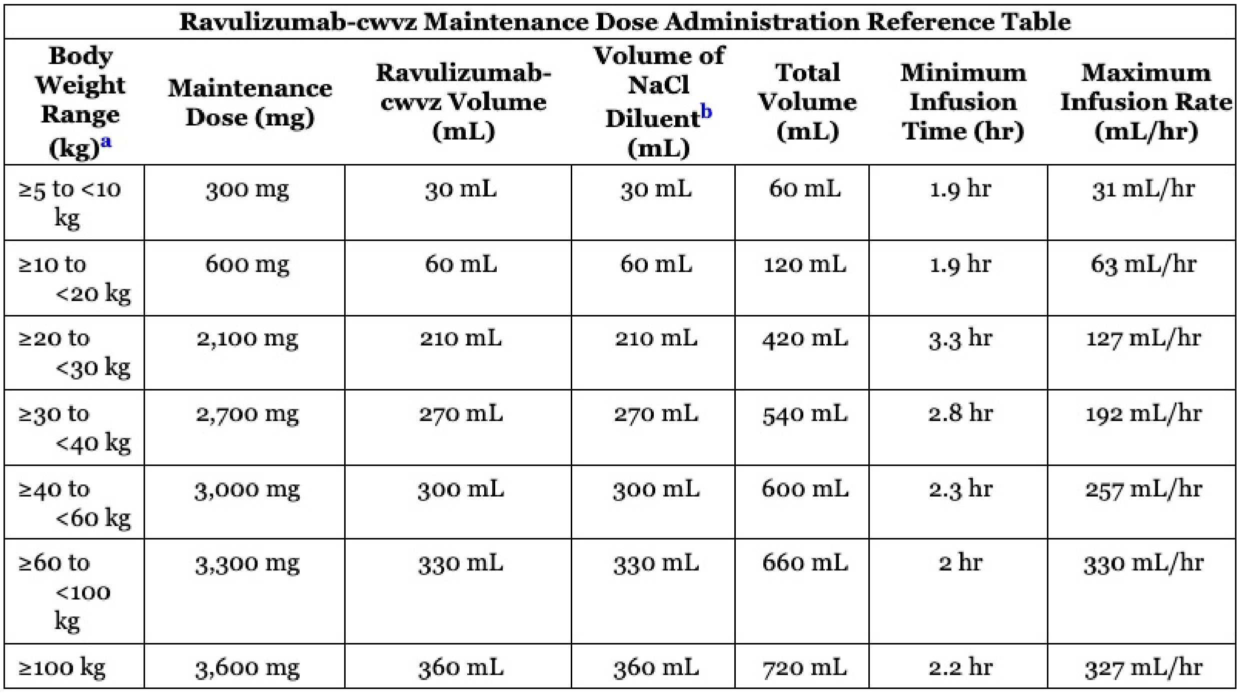


Ravulizumab-cwvz Loading Dose Administration Reference Table

Body Weight Range (kg)[a]	Loading Dose (mg)	Ravulizumab-cwvz Volume (mL)	Volume of NaCl Diluent[b] (mL)	Total Volume (mL)	Minimum Infusion Time (hr)	Maximum Infusion Rate (mL/hr)
≥5 to <10 kg	600 mg	60 mL	60 mL	120 mL	3.8 hr	31 mL/hr
≥10 to <20 kg	600 mg	60 mL	60 mL	120 mL	1.9 hr	63 mL/hr
≥20 to <30 kg	900 mg	90 mL	90 mL	180 mL	1.5 hr	120 mL/hr
≥30 to <40 kg	1,200 mg	120 mL	120 mL	240 mL	1.3 hr	184 mL/hr
≥40 to <60 kg	2,400 mg	240 mL	240 mL	480 mL	1.9 hr	252 mL/hr
≥60 to <100 kg	2,700 mg	270 mL	270 mL	540 mL	1.7 hr	317 mL/hr
≥100 kg	3,000 mg	300 mL	300 mL	600 mL	1.8 hr	333 mL/hr

[a] Body weight at time of treatment.

[b] Dilute ravulizumab-cwvz using only 0.9% sodium chloride injection, USP.



Ravulizumab-cwvz Maintenance Dose Administration Reference Table						
Body Weight Range (kg)[a]	Maintenance Dose (mg)	Ravulizumab-cwvz Volume (mL)	Volume of NaCl Diluent[b] (mL)	Total Volume (mL)	Minimum Infusion Time (hr)	Maximum Infusion Rate (mL/hr)
≥5 to <10 kg	300 mg	30 mL	30 mL	60 mL	1.9 hr	31 mL/hr
≥10 to <20 kg	600 mg	60 mL	60 mL	120 mL	1.9 hr	63 mL/hr
≥20 to <30 kg	2,100 mg	210 mL	210 mL	420 mL	3.3 hr	127 mL/hr
≥30 to <40 kg	2,700 mg	270 mL	270 mL	540 mL	2.8 hr	192 mL/hr
≥40 to <60 kg	3,000 mg	300 mL	300 mL	600 mL	2.3 hr	257 mL/hr
≥60 to <100 kg	3,300 mg	330 mL	330 mL	660 mL	2 hr	330 mL/hr
≥100 kg	3,600 mg	360 mL	360 mL	720 mL	2.2 hr	327 mL/hr

[a] Body weight at time of treatment.

[b] Dilute ravulizumab-cwvz using only 0.9% sodium chloride injection, USP.

Filters:

Administer only through a 0.2- or a 0.22-micron filter.

Storage:

Store ravulizumab-cwvz vials refrigerated at 2° to 8° C (36° to 46° F) in original carton and protect from light. Do not freeze. Do not shake. If diluted solution is not used immediately, storage under refrigeration at 2° to 8° C (36° to 46° F) must not exceed 24 hours, taking into account the expected infusion time. Once removed from refrigeration, administer the diluted ravulizumab-cwvz infusion solution within 6 hours. Protect from light. Do not freeze or shake.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer through a 0.2- or a 0.22-micron filter. Administer as an IV infusion as outlined in the reference charts in Dilution.

ACTIONS

Ravulizumab-cwvz is a terminal complement inhibitor that specifically binds to the complement protein C5 with high affinity, thereby inhibiting its cleavage to C5a (the proinflammatory anaphylatoxin) and C5b (the initiating subunit of the terminal complement complex [C5b-9]) and preventing the generation of the terminal complement complex C5b-9. Ravulizumab-cwvz inhibits terminal complement-mediated intravascular hemolysis in patients with PNH and complement-mediated thrombotic microangiopathy (TM) in patients with aHUS. The mean terminal elimination half-lives in patients with PNH and aHUS are 49.7 and 51.8 days, respectively.

INDICATIONS AND USES

Treatment of adult patients with paroxysmal nocturnal hemoglobinuria (PNH). ■ Treatment of adult and pediatric patients 1 month of age and older with atypical hemolytic uremic syndrome (aHUS) to inhibit complement-mediated thrombotic microangiopathy (TMA).

Limitation of Use:

Ravulizumab-cwvz is not indicated for the treatment of patients with Shiga toxin *E. coli*–related hemolytic uremic syndrome (STEC-HUS).

CONTRAINDICATIONS

Patients with unresolved *Neisseria meningitidis* infection. ■ Patients who are not currently vaccinated against *N. meningitidis* unless the risks of delaying ravulizumab-cwvz treatment outweigh the risks of developing a meningococcal infection.

PRECAUTIONS

For IV infusion only. ■ Life-threatening meningococcal infection/sepsis has occurred. Meningococcal infection may become rapidly life-threatening or fatal if not recognized and treated early. ■ Comply with the most current ACIP recommendations for meningococcal vaccination in patients with complement deficiencies. Revaccinate according to current medical guidelines, considering the duration of ravulizumab-cwvz therapy. ■ A meningococcal vaccine must be administered at least 2 weeks before administering the first dose of ravulizumab-cwvz unless the risk of delaying ravulizumab-cwvz therapy outweighs the risk of developing a meningococcal infection. Vaccination reduces, but does not eliminate, the risk of meningococcal infections. ■ Ravulizumab-cwvz blocks terminal complement activation; therefore there is an increased susceptibility to encapsulated bacterial infections, especially infections caused by *N. meningitidis* but also *Streptococcus pneumoniae, Hemophilus influenzae* and, to a lesser extent, *Neisseria gonorrhoeae*. Administer vaccinations for the prevention of *S. pneumoniae* and *H. influenzae* type b (Hib) according to ACIP guidelines. ■ Infusion reactions have occurred. However, in clinical trials these reactions did not require discontinuation of therapy. ■ Continue established anticoagulant therapy during ravulizumab-cwvz treatment; the effect of withdrawal of anticoagulant therapy during ravulizumab-cwvz therapy has not been established. ■ Ravulizumab-cwvz is available only through a restricted program under a Risk Evaluation and Mitigation Strategy (REMS). Under the ravulizumab-cwvz REMS, prescribers must enroll in the program. ■ Treatment of aHUS should be a minimum duration of 6 months. Treatment duration beyond the initial 6 months should be individualized. ■ As with all therapeutic proteins, there is a risk of immunogenicity.

Monitor:

Closely monitor for early S/S of meningococcal infection (moderate to severe headache with nausea or vomiting, fever, or a stiff neck or stiff back; fever of 39.4° C [103° F] or higher; fever and a rash; confusion; and/or severe muscle aches with flu-like symptoms and light sensitivity) and evaluate patients immediately if infection is suspected. Consider discontinuation in patients who are undergoing treatment for serious meningococcal infection. ■ Monitor for other types of infections or S/S of a worsening infection. ■ Monitor for S/S of an infusion or hypersensitivity reaction (drop in blood pressure, infusion-related pain, and lower back pain) during infusion and for at least 1 hour after infusion. Slow or discontinue the infusion at the discretion of the physician. ■ Monitor PNH patients who discontinue ravulizumab-cwvz for a minimum of 16 weeks to detect hemolysis identified by elevated LDH along with sudden decrease in PNH clone size or hemoglobin and to detect reappearance of symptoms such as fatigue, hemoglobinuria, abdominal pain, shortness of breath, major adverse vascular event (including thrombosis), dysphagia, or erectile dysfunction. If S/S of hemolysis occur after discontinuation, consider restarting therapy. ■ Monitor aHUS patients who discontinue ravulizumab-cwvz therapy for a minimum of 12 months for TMA complications. TMA complications may be identified by clinical symptoms (e.g., angina, changes in mental status, dyspnea, increasing BP, seizure, or thrombosis) in addition to at least two of the following laboratory values observed concurrently (and confirmed by a second measurement 28 days apart): a decrease in platelet count of 25% or more compared with baseline or peak platelet count during treatment, an increase in SCr of 25% or more as compared with baseline or to nadir during treatment, or an increase in serum LDH of 25% or more as compared with baseline or to nadir during treatment. If S/S of TMA complications occur after discontinuation, consider restarting therapy. ■ See Antidote.

Patient Education:

Read the patient medication guide before initiating ravulizumab-cwvz. ■ Meningococcal vaccination is required 2 weeks before initiating therapy if not previously vaccinated. Vaccination may not prevent meningococcal infection. Seek immediate medical attention if confusion, eyes sensitive to light, fever with or without a rash, headache associated with fever, nausea, vomiting, stiff back or neck, or muscle aches with flu-like symptoms occur. ■ Carry ravulizumab-cwvz patient safety card at all times. ■ Promptly report other S/S of an infection. Prevent gonorrheal infections; patients at risk should be tested regularly. ■ Promptly report chills, dyspnea, and/or itching during or soon after an infusion. ■ Patients with PNH or aHUS may develop hemolysis or TMA, respectively, when ravulizumab-cwvz therapy is discontinued. Prolonged monitoring (at least 16 weeks for patients with PNH and at least 12 months for patients with aHUS) is required. If ravulizumab-cwvz therapy is discontinued, keep Ultomiris Patient Safety Card on self for 8 months after the last dose.

Maternal/Child:

There are no available data on ravulizumab-cwvz use in pregnant women. However, paroxysmal nocturnal hemoglobinuria (PNH) in pregnancy is associated with adverse maternal outcomes, including worsening cytopenias, thrombotic events, infections, bleeding, miscarriages, and increased maternal mortality; as well as adverse fetal outcomes, including fetal death and premature delivery. aHUS is associated with adverse maternal outcomes, including pre-eclampsia and preterm delivery, and adverse fetal/neonatal outcomes, including intrauterine growth restriction, fetal death, and low birth weight. ■ Discontinue breast-feeding during treatment and for 8 months after the final dose. ■ The safety and efficacy of ravulizumab-cwvz for the treatment of PNH in pediatric patients have not been established. The safety and efficacy of ravulizumab-cwvz for the treatment of aHUS in pediatric patients 1 month of age and older have been established.

Elderly:

Clinical studies of ravulizumab-cwvz did not include sufficient numbers of subjects 65 years of age and older to determine whether they respond differently from younger subjects.

DRUG/LAB INTERACTIONS

Continue established anticoagulant therapy during ravulizumab-cwvz treatment; the effect of withdrawal of anticoagulant therapy during ravulizumab-cwvz therapy has not been established.

SIDE EFFECTS

PNH:

The most frequent side effects (>10%) were headache and upper respiratory tract infection. Serious side effects reported included fever and hyperthermia. Fatal sepsis has also occurred. Other side effects included abdominal pain, arthralgia, diarrhea, dizziness, nausea, and pain in extremity.

aHUS:

The most frequent side effects (>20%) were diarrhea, fever, headache, hypertension, nausea, upper respiratory tract infections, and vomiting. Serious side effects reported included abdominal pain, hypertension, and pneumonia. Fatal sepsis has also occurred. Other side effects included alopecia, anemia, anxiety, arthralgia, back pain, constipation, cough, decreased appetite, decreased vitamin D, dry skin, dyspnea, edema, fatigue, GI infection, hypokalemia, hypotension, iron deficiency, lymphadenopathy, myalgia, pain in extremities, rash, tonsillitis, and urinary tract infection.

ANTIDOTE

Keep physician informed of all side effects. If an adverse reaction occurs during administration, slow or discontinue the infusion at the discretion of the physician. Interrupt ravulizumab-cwvz infusion and institute appropriate supportive measurements if signs of cardiovascular instability or respiratory compromise occur.

RAXIBACUMAB

(rack-see-**BACK**-u-mab)
Monoclonal antibody
Antidote
pH 6.5

USUAL DOSE

Premedication in adults:

Premedicate with diphenhydramine 25 to 50 mg within 1 hour before raxibacumab infusion to prevent or attenuate infusion reactions. May be given IV or PO depending on proximity to the start of the raxibacumab infusion.

Adults:

A single dose of 40 mg/kg as an infusion over 2 hours and 15 minutes.

PEDIATRIC DOSE

Premedication in pediatric patients:

Premedicate with an appropriate dose of diphenhydramine within 1 hour before raxibacumab infusion to prevent or attenuate infusion reactions. May be given IV or PO depending on proximity to the start of the raxibacumab infusion.

Dosage for pediatric patients:

Weight more than 40 kg:

A single dose of 40 mg/kg.

Weight more than 10 kg and up to 40 kg:

A single dose of 60 mg/kg.

Weight 10 kg or less:

A single dose of 80 mg/kg.

DOSE ADJUSTMENTS

No dose adjustments indicated based on age, gender, or race.

DILUTION

Available as a single-use vial that contains 1700 mg/34 mL (50 mg/mL). The recommended dose is weight-based and is given as an intravenous infusion after appropriate dilution in a **compatible** solution. The following chart outlines dose, diluent, total infusion volume, and infusion rate based on patient body weight.

Raxibacumab Dose, Diluents, Infusion Volumes, and Rates by Body Weight

	Preparation			Administration	
Body Weight	**Dose**	**Total Infusion Volume[a]**	**Type of Diluent**	**Infusion Rate**	
Adults					
	40 mg/kg	250 mL	NS	15 mL/hr	125 mL/hr
Pediatric Patients (Younger than 18 Years)					
<1 kg	80 mg/kg	7 mL	½ NS or NS	0.5 mL/hr	3.5 mL/hr
1 kg to <2 kg		15 mL		1 mL/hr	7 mL/hr
2 kg to <3 kg		20 mL		1.2 mL/hr	10 mL/hr
3 kg to <5 kg		25 mL		1.5 mL/hr	12 mL/hr
5 to 10 kg		40 mL		3 mL/hr	20 mL/hr
>10 kg to <15 kg	60 mg/kg	50 mL	NS	6 mL/hr	25 mL/hr
15 kg to <30 kg		100 mL		6 mL/hr	50 mL/hr
30 kg to 40 kg		125 mL		15 mL/hr	62.5 mL/hr
>40 kg	40 mg/kg	150 mL		15 mL/hr	75 mL/hr

[a] For patients requiring maximum fluid restriction, dilution factors can be adjusted at the discretion of the physician to a maximum concentration of 32 mg/mL.

Weight in kg × Dose in mg/kg = Calculated dose of raxibacumab in mg

Calculated dose in mg ÷ Raxibacumab concentration (50 mg/mL) = Required volume of raxibacumab in mL

Based on total infusion volume from the previous chart, prepare either a syringe or infusion bag as appropriate.

Bag preparation:

Select the appropriate size bag of **compatible** solution. Withdraw a volume of solution from the bag equal to the calculated volume in milliliters of raxibacumab and discard. Withdraw the calculated dose of raxibacumab from the vial and transfer into the prepared infusion bag. Gently invert bag to mix. ***Do not shake.***

Syringe preparation:

Select an appropriate size syringe for the total volume of infusion to be administered. Using this syringe, withdraw the calculated raxibacumab dose. Then withdraw an appropriate amount of **compatible** solution to prepare a total volume infusion syringe as specified in the chart. Gently mix. ***Do not shake.***

Filters:

Not required by manufacturer; additional data not available.

Storage:

Store in original carton until time of use to protect from light. Refrigerate at 2° to 8° C (36° to 46° F). Do not freeze. Discard unused raxibacumab. Prepared solution stable for 8 hours at RT.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer as outlined in the chart under Dilution. Total infusion time is 2 hours and 15 minutes. Slow or interrupt the infusion for infusion-related symptoms or other side effects.

ACTIONS

A human IgG1λ monoclonal antibody. Produced by recombinant DNA technology in a murine cell expression system. It does not have direct antibacterial activity but binds to the protective antigen (PA) of *B. anthracis* toxin. Raxibacumab inhibits the binding of the PA to its cellular receptor. This prevents the intracellular entry of the anthrax lethal factor and edema factor, the enzymatic toxin components responsible for the pathogenic effects of the anthrax toxin. Mean steady-state volume of distribution was greater than plasma volume, suggesting some tissue distribution. Virtually no renal clearance occurs.

INDICATIONS AND USES

Treatment of adult and pediatric patients with inhalation anthrax due to *Bacillus anthracis* in combination with the appropriate antibacterial drugs. ■ Prophylaxis of inhalation anthrax when alternative therapies are not appropriate or available for use.

Limitations of use:

Effectiveness based solely on efficacy studies in animal models of inhalational anthrax. ■ Does not cross the blood-brain barrier and does not prevent or treat meningitis. ■ Does not have direct antibacterial activity. Should be used in combination with appropriate antibacterial drugs. ■ See Maternal/Child.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Infusion-related reactions have been reported; see Monitor and Antidote. ■ A protein product; has the potential for immunogenicity. ■ Adequate laboratory and supportive medical resources must be available.

Monitor:

Premedication required; see Usual Dose. ■ Monitor for infusion-related reactions during administration (e.g., pruritus, rash, urticaria) and slow or interrupt infusion as indicated.

Patient Education:

Read FDA-approved patient information. Promptly report S/S of an infusion reaction (e.g., hives, itching, rash). ■ The effectiveness of raxibacumab is based on studies done in animals and has not been tested in humans with anthrax.

Maternal/Child:

Safety for use in pregnancy, breast-feeding, and pediatric patients not established. Case reports of anthrax infection in pregnant women indicate that maternal infection is associated with a high risk of maternal, fetal, and neonatal deaths, particularly in the absence of treatment. Use raxibacumab only if clearly needed. ■ As in adults, effectiveness in pediatric patients is based solely on efficacy studies in animal models. Safety and pharmacokinetics of raxibacumab were studied in healthy adult volunteers. There are no studies of safety or pharmacokinetics in pediatric patients. An extrapolation approach was used to derive dosing regimens in pediatric patients.

Elderly:

Numbers in clinical studies insufficient to determine whether the elderly respond differently compared with younger subjects.

DRUG/LAB INTERACTIONS

The pharmacokinetics of ciprofloxacin and raxibacumab was not altered with coadministration of 40 mg/kg raxibacumab IV and either IV or oral ciprofloxacin.

In a study determining the efficacy of the drugs in the treatment of animals with systemic anthrax disease, the pharmacokinetics of levofloxacin and raxibacumab was unaffected by product coadministration.

SIDE EFFECTS

The most frequently reported side effects were pain in extremities, pruritus, rash, and somnolence. Anemia, back pain, dyspnea, fatigue, flushing, hypertension, increased blood amylase and blood creatine phosphokinase, infusion site pain, insomnia, leukopenia, lymphadenopathy, muscle spasms, palpitations, peripheral edema, prolonged PT, vasovagal syncope, and vertigo have been reported.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. If signs of an infusion reaction occur, slow or interrupt the infusion and treat appropriately. No cases of overdose have been observed. If overdose occurs, monitor for any signs or symptoms of adverse effects and apply appropriate medical therapies.

REGADENOSON

(re-ga-**DEN**-oh-son)
Lexiscan
Diagnostic agent
pH 6.3 to 7.7

USUAL DOSE

Pretreatment:

Avoid consumption of any products containing methylxanthines for at least 12 hours before the study, including caffeinated coffee, tea, or other caffeinated beverages; caffeine-containing drug products; aminophylline; and theophylline. See Drug/Lab Interactions and Patient Education.

Regadenoson:

0.4 mg (5 mL) as an IV injection. Given undiluted into a peripheral vein using a 22-gauge or larger catheter or needle. Immediately following dose, flush line with 5 mL of NS. Administer the radionuclide myocardial perfusion imaging agent 10 to 20 seconds after the NS flush. The radionuclide may be injected directly into the same catheter as the regadenoson.

DOSE ADJUSTMENTS

No dose adjustment is indicated based on age, gender, and race or for patients with hepatic or renal impairment, including patients with ESRD and/or patients on dialysis.

DILUTION

Solution must be clear. Do not use if discolored or if particulate matter is present. Available in a single-use 0.4 mg/5 mL syringe. Given undiluted into a peripheral vein using a 22-gauge or larger catheter or needle.

Filter:

Information not available.

Storage:

Store at CRT.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer as an IV injection within 10 seconds.

ACTIONS

An adenosine receptor agonist that is a coronary vasodilator. It is a low-affinity agonist for the A_{2A} adenosine receptor. Activation of this receptor produces coronary vasodilation and a rapid increase in coronary blood flow that is sustained for a short duration. Mean average peak velocity of coronary blood flow increases to greater than twice the baseline level by 30 seconds and decreases to less than twice the baseline level within 10 minutes. Myocardial uptake of the radiopharmaceutical is proportional to coronary blood flow. Because regadenoson increases blood flow in normal coronary arteries with little or no increase in stenotic arteries, there is relatively less uptake of the radiopharmaceutical in areas of the heart supplied by stenotic arteries. Myocardial perfusion imaging intensity after administration is therefore greater in areas perfused by normal arteries than in areas perfused by stenosed arteries. Additional hemodynamic effects, which may be seen within 45 minutes of administration, include an increase in heart rate and a decrease in blood pressure. Peak plasma concentrations are achieved within 1 to 4 minutes. Half-life is approximately 2 hours. Metabolism is unknown. Excreted primarily as unchanged drug in the urine.

INDICATIONS AND USES

A pharmacologic stress agent indicated for radionuclide myocardial perfusion imaging (MPI) in patients unable to undergo adequate exercise stress.

CONTRAINDICATIONS

Second- or third-degree AV block or sinus node dysfunction unless a functioning artificial pacemaker is in place.

PRECAUTIONS

Fatal and nonfatal myocardial infarction, ventricular arrhythmias, and cardiac arrest have occurred following regadenoson injection. Avoid use in patients with S/S of acute myocardial ischemia (e.g., cardiovascular instability or unstable angina); may be at greater risk for serious cardiovascular reactions. Emergency resuscitation medications and equipment must be readily available. ■ Adhere to the recommended duration of injection. ■ Hypersensitivity reactions, including anaphylaxis, have been reported; see Monitor. ■ May produce clinically significant increases in BP. These increases usually occur within minutes of administration and resolve within 10 to 15 minutes. These BP increases have lasted as long as 45 minutes in some patients; more often seen in patients with a history of hypertension and/or when myocardial perfusion imaging includes low-level exercise. ■ Can depress the SA and AV nodes and may cause sinus bradycardia or first-, second-, or third-degree AV block, requiring intervention. ■ New-onset or recurrent atrial fibrillation with rapid ventricular response and atrial flutter have been reported following regadenoson administration. ■ Induces arterial vasodilation and hypotension. In trials, hypotension was seen within 45 minutes of administration. Risk of serious hypotension may be higher in patients with autonomic dysfunction, hypovolemia, left main coronary artery stenosis, stenotic valvular heart disease, pericarditis or pericardial effusions, or stenotic carotid artery disease with cerebrovascular insufficiency. ■ May cause dyspnea, bronchoconstriction, and respiratory compromise. Use with caution in patients with known or suspected bronchoconstrictive disease, COPD, or asthma. Appropriate bronchodilator therapy and resuscitative measures should be readily available. ■ May lower the seizure threshold. New-onset or recurrence of convulsive seizures has occurred following administration. Seizures may be prolonged and require emergent anticonvulsive management. ■ Hemorrhagic and ischemic cerebrovascular accidents have been reported. Hemodynamic effects such as hypotension and hypertension may be associated with these adverse effects.

Monitor:

ECG monitoring during administration and imaging is recommended. ■ Monitor BP and HR. ■ Obtain a seizure history; use of aminophylline may increase the risk of seizures. ■ Monitor respiratory status. ■ Monitor for S/S of hypersensitivity reactions (e.g., angioedema, cardiac or respiratory arrest, decreased oxygen saturation, hypotension, respiratory distress, throat tightness, rashes, and urticaria).

Patient Education:

Avoid consumption of any products containing methylxanthines for at least 12 hours before the study, including caffeinated coffee, tea, or other caffeinated beverages; caffeine-containing drug products; aminophylline; and theophylline. Report any history of seizures. ■ Promptly report side effects such as shortness of breath, headache, and flushing. ■ Increased cardiovascular risks have been associated with regadenoson ■ Patients with COPD or asthma should discuss respiratory history and the administration of pre-study and post-study bronchodilator therapy before scheduling a study.

Maternal/Child:

Data not available. Use caution and consider risk versus benefit. ■ Interrupt breast-feeding; pump and discard breast milk for 10 hours after administration of regadenoson. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Older patients have a similar side effect profile compared with younger patients but may have a higher incidence of hypotension.

DRUG/LAB INTERACTIONS

Formal pharmacokinetic drug interaction studies have not been conducted. ■ **Methylxanthines** (e.g., aminophylline, caffeine, and theophylline) are nonspecific adenosine receptor antagonists and may interfere with the vasodilation activity of regadenoson. Separate the administration of theophylline preparations or the consumption of any products containing methylxanthines from the administration of regadenoson by at least 12 hours. ■ **Aminophylline** (a methylxanthine) may be used to attenuate severe or persistent adverse reactions to regadenoson, but its use is not recommended for patients who experience a seizure in association with regadenoson administration. ■ **Dipyridamole** (Persantine) or **aspirin and dipyridamole** (Aggrenox) may change the effects of regadenoson. When possible, hold dipyridamole or aspirin and dipyridamole for at least 2 days before regadenoson administration. ■ Has been administered to patients taking other cardioactive drugs, including beta-blockers (e.g., metoprolol [Lopressor]), calcium channel blockers (e.g., diltiazem [Cardizem]), ACE inhibitors (lisinopril [Zestril]), nitrates (nitroglycerin), cardiac glycosides (e.g., digoxin [Lanoxin]), and angiotensin receptor blockers (e.g., losartan [Cozaar]). ■ Does not appear to alter the pharmacokinetics of drugs metabolized by the cytochrome P_{450} system.

SIDE EFFECTS

Most side effects begin soon after dosing and generally resolve within approximately 15 minutes, except for headache, which resolves in most patients within 30 minutes. The most common side effects are angina pectoris, chest pain or discomfort, dizziness, dyspnea, flushing, headache, and nausea. Other side effects include abdominal discomfort, bronchoconstriction, dysgeusia, ECG abnormalities (e.g., ST-segment depression, first- or second-degree AV block, conduction abnormalities, PACs, PVCs), and feeling hot.

Overdose:

Dizziness, flushing, increased heart rate.

Post-Marketing:

Abdominal pain (may be severe) with myalgias, nausea, and vomiting; acute coronary syndrome; atrial flutter; cardiac arrest; cerebrovascular accident, including intracranial hemorrhage; diarrhea and fecal incontinence; dyspnea and wheezing; heart block (including third-degree block) and asystole; hypersensitivity reactions (including anaphylaxis, angioedema, cardiac arrest, decreased oxygen saturation, hypotension, rashes, respiratory arrest, respiratory distress, throat tightness, and urticaria); marked hypertension; musculoskeletal pain in the arms, lower back, buttocks, and lower legs; myocardial infarction; QTc prolongation; respiratory arrest; seizures and syncope; symptomatic hypotension in association with transient ischemic attack; supraventricular tachyarrhythmias, including atrial fibrillation with rapid ventricular response (new onset or recurrent); tremor; and ventricular arrhythmias.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Aminophylline (50 to 250 mg IV at a rate of 50 to 100 mg over 30 to 60 seconds) may be administered to attenuate most severe and/or persistent side effects. Aminophylline may increase the risk of seizures associated with regadenoson injection and is not recommended for patients who experience a seizure in association with regadenoson administration. Treat hypersensitivity reactions, seizures, and conduction abnormalities as indicated. Resuscitate as necessary.

REMDESIVIR

(rem-**DE**-si-vir)
Veklury
Antiviral
COVID-19 Emergency Use Authorization, October 2020.

USUAL DOSE

200 mg IV on Day 1 followed by 100 mg once daily. Duration varies; generally 5 to 10 days based on specific patient needs and parameters.

PEDIATRIC DOSE

Weight 3.5 kg to less than 40 kg:

5 mg/kg/dose on Day 1 followed by 2.5 mg/kg/dose once daily.

Weight greater than 40 kg:

200 mg IV on Day 1 followed by 100 mg IV once daily.

DOSE ADJUSTMENTS

Renal:

No dosage adjustment is required; however, no formal safety or pharmacokinetic data are available. The manufacturer does not recommend use for patients with eGFR less than 30 mL/min; however, short-term use is unlikely to result in significant toxicity.

Hepatic:

No dosage adjustments are provided by the manufacturer. Studies suggest that if ALT is greater than 10 times the ULN; consider discontinuation. The drug should be discontinued if patient also exhibits signs of liver inflammation along with ALT elevation.

DILUTION

Preparation should occur on the day of administration. Diluted preparations in IV bags can be stored for 24 hours at room temperature or for 48 hours under refrigeration.

Injection solution concentrate (5 mg/mL) for adults and pediatric patients 40 kg or greater:

Prior to dilution, allow injection solution vial to warm to room temperature. Withdraw and discard the required volume of NS from the infusion bag (40 mL for a 200-mg dose; 20 mL for a 100-mg dose). Transfer required volume of remdesivir, based on dose, to a 250-mL infusion bag and gently invert 20 times to mix the solution; ***do not shake***. Discard unused portion.

Lyophilized powder for adults and pediatric patients 40 kg or greater:

Reconstitute vial with 19 mL SWI only. **Note:** Discard vial if a vacuum does not pull diluent into the vial. Shake for 30 seconds; allow vial contents to settle for 2 to 3 minutes. If not completely dissolved, repeat process until vial contents are completely dissolved. Reconstituted vial contains 100 mg per 20 mL (5 mg/mL). Prior to adding remdesivir to IV bag, withdraw and discard the required volume of NS (100-mL or 250-mL bag) from the infusion bag (40 mL for a 200-mg dose; 20 mL for a 100-mg dose). Transfer required volume of remdesivir, based on dose, to the infusion bag and invert gently 20 times to mix the solution; ***do not shake***. Discard unused portion.

Pediatric patients 3.5 kg to less than 40 kg:

Reconstitute 100-mg vial with 19 mL SWI only. **Note:** Discard vial if a vacuum does not pull diluent into the vial. Shake for 30 seconds; allow vial contents to settle for 2 to 3 minutes. If not completely dissolved, repeat process until vial contents are completely dissolved. Reconstituted vial contains 100 mg per 20 mL (5 mg/mL). Further dilute dose in NS to a final concentration of 1.25 mg/mL; an infusion bag or syringe (for volumes <50 mL) may be used. Use the patient-specific remdesivir dose to determine the total infusion volume required to achieve a final concentration of 1.25 mg/mL.

Syringe:

Withdraw the required volume of the reconstituted remdesivir solution for the patient-specific dose into the syringe, followed by the required volume of NS to achieve the final concentration of 1.25 mg/mL. Mix the solution by gently inverting the syringe 20 times after dilution. ***Do not shake***.

Prefilled NS bag:

From a bag of NS, withdraw a volume equal to the volume of the reconstituted remdesivir dose, plus additional volume as needed to result in a final concentration of 1.25 mg/mL. Withdraw the required volume of the reconstituted remdesivir solution for the patient-specific dose and add to the NS infusion bag. Gently invert the bag 20 times to mix the solution in the bag. ***Do not shake***.

Empty infusion bag:

Withdraw the required volume of the reconstituted remdesivir solution for the patient-specific dose and add to the empty infusion bag. Add the required volume of NS to the bag to achieve a final concentration of 1.25 mg/mL. Gently invert the bag 20 times to mix the solution in the bag. ***Do not shake***.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than normal saline.

RATE OF ADMINISTRATION

Administer as an IV infusion over 30 to 120 minutes.

ACTIONS

Remdesivir inhibits the SARS-CoV-2 RNA-dependent RNA polymerase (RdRp), which is necessary for viral replication. Remdesivir is a prodrug that is metabolized to the active nucleoside triphosphate metabolite, which then competes for incorporation into RNA chains, resulting in delayed chain termination during viral RNA replication. Remdesivir triphosphate can also inhibit viral RNA synthesis due to incorporation into the viral RNA template.

INDICATIONS AND USES

Remdesivir is FDA-approved for treatment of COVID-19 in hospitalized patients. National guidelines vary on the role of remdesivir. The student is referred to the National Institutes of Health or the Infectious Disease Society of America for specifics. Remdesivir should be used only in hospitalized patients.

CONTRAINDICATIONS

Hypersensitivity to remdesivir or any component of the formulation.

PRECAUTIONS

Hypersensitivity and infusion-related reactions:

Hypersensitivity reactions, including anaphylactic and infusion-related reactions, have been reported during and after administration.

Hepatic effects:

Elevated transaminases. Consider discontinuation in patients who develop ALT greater than 10 times the ULN, and discontinue if symptoms of liver inflammation appear.

Renal function impairment:

Although the manufacturer recommends against use in patients with eGFR less than 30 mL/min, significant toxicity with a short duration of therapy (5 to 10 days) is unlikely.

Injectable dosage Form:

Remdesivir contains cyclodextrin (sulfobutylether-beta-cyclodextrin; 6 g per 100 mg remdesivir [injection solution] or 3 g per 100 mg remdesivir [lyophilized powder]) as an excipient, which may accumulate in patients with renal impairment. The manufacturer recommends use of only the lyophilized powder in pediatric patients under 12 years of age or weighing less than 40 kg.

Monitor:

Monitor for signs and symptoms of hypersensitivity reactions, including anaphylaxis, and for signs of liver inflammation. As clinically appropriate, monitor liver function and renal function tests.

Patient Education:

Promptly report any signs of hypersensitivity (e.g., difficulty breathing, hives, itching, rash) or liver problems (e.g., dark urine, stomach pain, light-colored stools, or yellow skin or eyes) or infusion-related reactions (nausea, vomiting, sweating, shivering, dizziness).

Maternal/Child:

Based on preliminary data, use in pregnant women should not be withheld if it is clinically needed. It is not known if remdesivir passes into breast milk.

Elderly:

Refer to Usual Dose and Precautions.

DRUG/LAB INTERACTIONS

Choloroquine, hydroxychloroquine, and strong CYP-3A4 inducers may decrease the effectiveness of remdesivir.

SIDE EFFECTS

Skin rash, nausea, prolonged PT, elevated transaminases, hypersensitivity, seizures.

ANTIDOTE

Discontinue infusion and treat appropriately for severe hypersensitivity reactions. Stop treatment if ALTs are greater than 10 times the ULN.

REMIFENTANIL HYDROCHLORIDE BBW

(rem-ih-**FEN**-tah-nil hy-droh-**KLOR**-eyed)
Ultiva
Opioid analgesic (agonist)
Anesthesia adjunct
pH 2.5 to 3.5

USUAL DOSE

Pretreatment:

See Maternal/Child.

General anesthesia and continuing as an analgesic into the immediate postoperative period:

Not recommended as the sole anesthetic agent because it may not cause loss of consciousness and it has a high incidence of apnea, muscle rigidity, and tachycardia. Given concomitantly with reduced doses of other anesthetics (e.g., isoflurane, midazolam [Versed], propofol [Diprivan]); see Dose Adjustments and Drug/Lab Interactions. Individualize based on patient response. May be premedicated with benzodiazepines (e.g., diazepam [Valium], midazolam [Versed]). See the following charts.

Remifentanil Dosing Guidelines in Adults for General Anesthesia and Continuing as an Analgesic Into the Postoperative Care Unit or Intensive Care Setting

Phase	Continuous IV Infusion of Remifentanil (mcg/kg/min)	Range of Infusion Dose of Remifentanil (mcg/kg/min)	Supplemental IV Bolus Dose of Remifentanil (mcg/kg)
Induction of anesthesia (through intubation)	0.5-1[a] mcg/kg/min		
Maintenance of anesthesia with:			
Nitrous oxide (66%)	0.4 mcg/kg/min	0.1-2 mcg/kg/min	1 mcg/kg
Isoflurane (0.4-1.5 MAC)	0.25 mcg/kg/min	0.05-2 mcg/kg/min	1 mcg/kg
Propofol (100-200 mcg/kg/min)	0.25 mcg/kg/min	0.05-2 mcg/kg/min	1 mcg/kg
Continuation as an analgesic into immediate postoperative period	0.1 mcg/kg/min	0.025-0.2 mcg/kg/min	Not recommended

[a] If intubation is to occur less than 8 minutes after the start of a remifentanil infusion, an initial dose of 1 mcg/kg may be administered over 30 to 60 seconds.

Remifentanil Dosing Guidelines for Monitored Anesthesia Care (MAC)

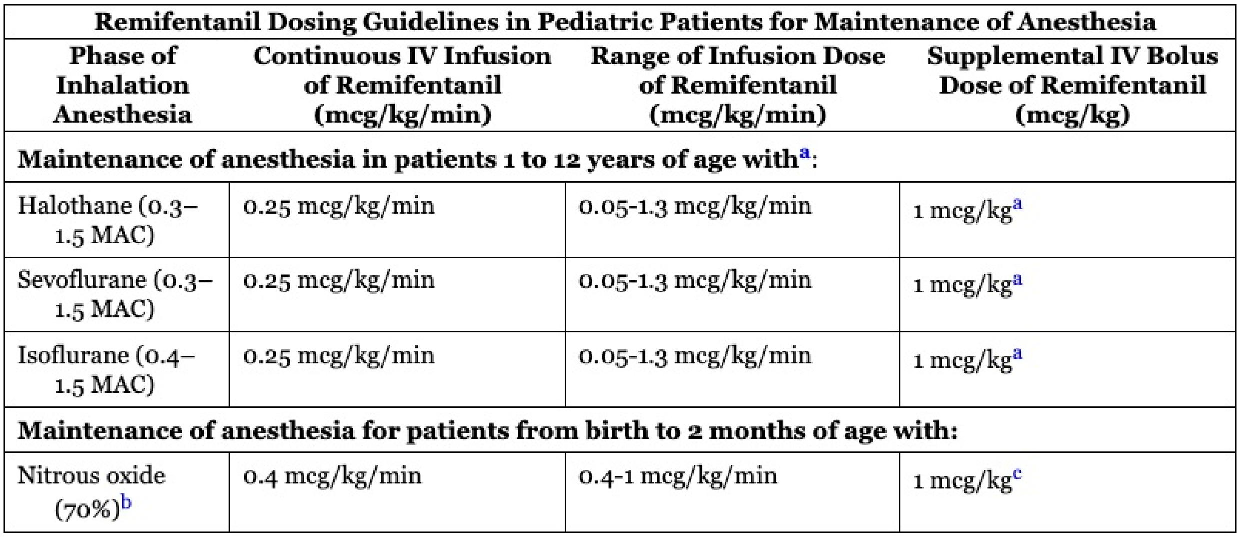
Method	Timing	Remifentanil Alone	Remifentanil Plus 2 mg Midazolam
Single IV dose	Given 90 seconds before local anesthetic	1 mcg/kg over 30-60 seconds	0.5 mcg/kg over 30-60 seconds
Continuous IV infusion	Beginning 5 minutes before local anesthetic	0.1 mcg/kg/min	0.05 mcg/kg/min
	After local anesthetic	0.05 mcg/kg/min (Range: 0.025-0.2 mcg/kg/min)	0.025 mcg/kg/min (Range: 0.025-0.2 mcg/kg/min)

It is strongly recommended that supplemental oxygen be supplied to the patient whenever remifentanil is administered.

PEDIATRIC DOSE

Pediatric patients birth to 12 years of age:

Note all comments under Usual Dose. Effectiveness and safety established only for use as an analgesic agent during maintenance of general anesthesia. 20 or 25 mcg/mL dilution recommended. In pediatric patients, remifentanil was administered with nitrous oxide or nitrous oxide in combination with halothane, sevoflurane, or isoflurane. See the following chart.



Remifentanil Dosing Guidelines in Pediatric Patients for Maintenance of Anesthesia			
Phase of Inhalation Anesthesia	**Continuous IV Infusion of Remifentanil (mcg/kg/min)**	**Range of Infusion Dose of Remifentanil (mcg/kg/min)**	**Supplemental IV Bolus Dose of Remifentanil (mcg/kg)**
Maintenance of anesthesia in patients 1 to 12 years of age with[a]:			
Halothane (0.3–1.5 MAC)	0.25 mcg/kg/min	0.05-1.3 mcg/kg/min	1 mcg/kg[a]
Sevoflurane (0.3–1.5 MAC)	0.25 mcg/kg/min	0.05-1.3 mcg/kg/min	1 mcg/kg[a]
Isoflurane (0.4–1.5 MAC)	0.25 mcg/kg/min	0.05-1.3 mcg/kg/min	1 mcg/kg[a]
Maintenance of anesthesia for patients from birth to 2 months of age with:			
Nitrous oxide (70%)[b]	0.4 mcg/kg/min	0.4-1 mcg/kg/min	1 mcg/kg[c]

[a] An initial dose of 1 mcg/kg may be administered over 30 to 60 seconds.

[b] The clearance rate in neonates is highly variable and on average is two times higher than in young healthy adults. Therefore an increased infusion rate may be necessary to maintain adequate surgical anesthesia, and additional bolus doses may be required. The use of atropine may blunt the potential for bradycardia that can occur with remifentanil.

[c] Bolus doses of 1 mcg/kg were studied in ASA 1 and 2 full-term infants weighing at least 2,500 Gm undergoing pyloromyotomy who received pretreatment with atropine. Neonates receiving supplementation with potent inhalation agents or neuraxial anesthesia, those who have significant comorbidities or are undergoing significant fluid shifts, or those who have not been pretreated with atropine may require smaller bolus doses to avoid hypotension and/or bradycardia.

DOSE ADJUSTMENTS

Reduce starting dose by 50% in elderly patients (over 65 years of age), then cautiously titrate to effect. ■ Base starting dose on ideal body weight in obese patients (more than 30% over their IBW). ■ No dose adjustment required in patients with renal or hepatic dysfunction. ■ Dose may be reduced up to 75% with other anesthetic agents; see Drug/Lab Interactions. ■ See Precautions. ■ Dosage modifications in coronary artery bypass surgery are outlined in the following chart.

Remifentanil Dosing Guidelines in Coronary Artery Bypass Surgery for General Anesthesia and Continuing as an Analgesic Into the Intensive Care Setting

Phase	Continuous IV Infusion of Remifentanil (mcg/kg/min)	Range of Infusion Dose of Remifentanil (mcg/kg/min)	Supplemental IV Bolus Dose of Remifentanil (mcg/kg)
Induction of anesthesia (through intubation)	1 mcg/kg/min		
Maintenance of anesthesia	1 mcg/kg/min	0.125–4 mcg/kg/min	0.5–1 mcg/kg
Continuation as an analgesic into ICU	1 mcg/kg/min	0.05–1 mcg/kg/min	

DILUTION

To reconstitute, add 1 mL of diluent for each mg of remifentanil (1 mg/mL). **Compatible** with SW, D5W, D5NS, NS, ½NS, and D5LR. Shake well. Must be further diluted to a final concentration of 20, 25, 50, or 250 mcg/mL with additional amounts of the above solutions (see the following chart). When used for MAC anesthesia, the 25 mcg/mL dilution is recommended. When used for ***pediatric dilution,*** 20 or 25 mcg/mL dilution is recommended.

Remifentanil Reconstitution and Dilution

Amount of Reconstituted Remifentanil in Each Vial	Amount of Diluent	Final Volume After Reconstitution and Dilution	Final Concentration
1 mg 2 mg 5 mg	49 mL 98 mL 245 mL	50 mL 100 mL 250 mL	20 mcg/mL
1 mg 2 mg 5 mg	39 mL 78 mL 195 mL	40 mL 80 mL 200 mL	25 mcg/mL
1 mg 2 mg 5 mg	19 mL 38 mL 95 mL	20 mL 40 mL 100 mL	50 mcg/mL
5 mg	15 mL	20 mL	250 mcg/mL

Storage:

Store between 2° and 25° C (36° and 77° F). Stable for 24 hours at RT after reconstituted and diluted with above solutions. Stability reduced to 4 hours with LR injection.

COMPATIBILITY

Compatible with propofol when coadministered into a running IV administration set.

Do not administer into the same IV tubing as blood or blood products.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Use of an infusion device required. Injection site should be close to the venous cannula, and all IV tubing should be flushed when the infusion is discontinued to prevent delayed effects. IV bolus administration should be used only during maintenance of general anesthesia. In nonintubated patients, single doses of remifentanil should be administered over 30 to 60 seconds. Skeletal muscle rigidity is related to the dose and speed of administration. In any situation infusion rates greater than 0.2 mcg/kg/min may cause respiratory depression. See charts in Usual Dose. Additional information for the different indications is listed below.

Anesthesia induction:

0.5 to 1 mcg/kg/min with a hypnotic or volatile agent for the induction of anesthesia. If intubation is to occur less than 8 minutes after the start of a remifentanil infusion, an initial dose of 1 mcg/kg over 30 to 60 seconds may be given.

Anesthesia maintenance:

Titrate upward in 25% to 100% increments or downward in 25% to 50% increments every 2 to 5 minutes to attain desired level of opioid effect. Supplemental bolus doses of 1 mcg/kg may be given every 2 to 5 minutes in response to light anesthesia or episodes of intense surgical stress. If infusion rates greater than 1 mcg/kg/min are required, consider increasing concomitant anesthetic agents to increase the depth of anesthesia.

Continuation as an analgesic during the immediate postoperative period:

Adjust rate in 0.025 mcg/kg/min increments every 5 minutes to balance level of analgesia and respiratory rate. Administer alternate analgesics to control postoperative pain before discontinuing remifentanil.

Monitored anesthesia care (MAC):

See chart in Usual Dose. 25 mcg/mL dilution recommended. May cause muscle rigidity and respiratory depression. See Contraindications and Precautions.

After placement of a local or regional block with MAC:

To reduce risk of hypoventilation, decrease infusion rate to 0.05 mcg/kg/min; thereafter titrate in increments of 0.025 mcg/kg/min at 5-minute intervals to balance level of analgesia and respiratory rate.

See the following charts for recommended infusion rates based on concentration.

Remifentanil IV Infusion Rates (mL/hr) for a 20-mcg/mL Solution							
Desired Infusion Rate (mcg/kg/min)	**Patient Weight (kg)**						
	5 kg	**10 kg**	**20 kg**	**30 kg**	**40 kg**	**50 kg**	**60 kg**

ACTIONS

An opioid agonist analgesic with rapid onset (1 minute) and peak effect (3 to 5 minutes) and short duration of action (5 to 10 minutes). Effects and side effects are dose dependent. There is direct correlation between dose, blood levels, and response. Blood concentration decreases 50% in 3 to 6 minutes after a 1-minute infusion or after prolonged continuous infusion due to rapid distribution and elimination and is independent of duration of drug administration. Recovery from effects occurs within 5 to 10 minutes. New steady-state concentrations occur within 5 to 10 minutes after changes in infusion rates. Rapidly metabolized by specific blood and tissue esterases and excreted in the urine.

INDICATIONS AND USES

An analgesic agent for use during induction and maintenance of general anesthesia for inpatient and outpatient procedures. ■ For continuation as an analgesic into the immediate postoperative period in adult patients under the direct supervision of an anesthesia practitioner in a postoperative anesthesia care unit or intensive care setting. ■ Analgesic component of monitored anesthesia care in adult patients.

CONTRAINDICATIONS

Known hypersensitivity to remif entanil. ■ Contains glycine; do not use for epidural or intrathecal administration. ■ ***IV bolus doses should be used only during the maintenance of general anesthesia. Administration of bolus doses simultaneously with a continuous infusion to spontaneously breathing patients is not recommended.***

PRECAUTIONS

For IV use only. ■ Remifentanil exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient's risk before prescribing remifentanil. ■ Strategies to reduce the risk of diversion or misuse should be used by health care facilities that use this and other controlled substances. ■ Remifentanil should be administered only by persons specifically trained in the use of IV anesthetics and management of the respiratory effects of potent opioids, including respiration and cardiac resuscitation. ■ Intended for use by or under the direct supervision of the anesthesiologist. Must have responsibility only for anesthesia during surgery and/or procedures. ■ Carbon dioxide retention from opioid-induced respiratory depression can exacerbate the sedating effects of opioids. ■ Use caution in patients with pulmonary disease or cor pulmonale and in patients with decreased respiratory reserve, hypoxia, hypercapnia, or pre-existing respiratory depression; these patients are at increased risk for decreased respiratory drive, including apnea. ■ Use caution in elderly, cachectic, or debilitated patients; these patients may be at an increased risk for adverse effects, including respiratory depression. Reduced dose may be indicated. ■ Cases of serotonin syndrome have been reported during concomitant use of remifentanil with serotonergic drugs. Symptoms may include mental status changes (e.g., agitation, coma, hallucinations), autonomic instability (e.g., hyperthermia, labile blood pressure, tachycardia), neuromuscular aberrations (e.g., hyperreflexia, incoordination, rigidity), and/or GI symptoms (e.g., diarrhea, nausea, vomiting). Onset of symptoms may occur within hours to days of concomitant use. ■ May cause muscle rigidity. Incidence and severity is rate- and dose-related. Chest wall rigidity (inability to ventilate) can occur after single doses of more than 1 mcg/kg administered over 30 to 60 seconds or infusion rates greater than

0.1 mcg/kg/min. May also cause chest wall rigidity with doses lower than 1 mcg/kg when given concurrently with a continuous infusion of remifentanil. Muscle rigidity should be managed in the context of the patient's clinical condition; see Antidote. ■ Bradycardia and hypotension have been reported. ■ Use caution in very obese patients; may have increased potential for cardiovascular or respiratory problems. ■ Intraoperative awareness has been reported. ■ Use caution in patients with head injury, brain tumors, or increased intracranial pressure. Respiratory depression may cause an increased P_{CO_2}, cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. ■ Use caution in patients with biliary tract disease, including acute pancreatitis. May cause spasm of the sphincter of Oddi. Opioids may cause increases in amylase. ■ Remifentanil may increase the frequency of seizures in patients with seizure disorders. ■ Has not been used for longer than 16 hours in ICU patients.

Monitor:

Monitor patient closely for respiratory depression when initiating therapy and after dosage increases. Oxygen, intubation equipment, controlled ventilation equipment, naloxone (Narcan), neuromuscular blocking agents (e.g., rocuronium [Zemuron]), and facilities for resuscitation and life support must always be available. Maintain a patent airway and ascertain adequate ventilation at all times. A conscious patient will appear to be asleep and may forget to breathe unless commanded to do so. ■ Can cause rigidity of respiratory muscles; may require a muscle relaxant (benzodiazepine) or neuromuscular blocking agent to relax muscles and permit artificial ventilation. ■ All vital signs must be monitored continuously. Use of a respiratory monitor and monitoring of oxygen saturation required. Supplemental oxygen always required for general anesthesia; strongly recommended for MAC. ■ Monitor for S/S of serotonin syndrome; see Precautions. ■ Keep patient supine; orthostatic hypotension and fainting may occur. ■ Flush IV line before discontinuing an infusion of remifentanil. ■ Establish adequate postoperative analgesia before discontinuing an infusion of remifentanil. ■ See Precautions. ■ Monitor for 30 to 60 minutes after anesthesia complete. Effect of remifentanil will be offset within 5 to 10 minutes, but respiratory depression may still occur from concomitant anesthetics. ■ Monitor patients who may be susceptible to the intracranial effects of CO_2 retention for increasing intracranial pressure and signs of sedation and respiratory depression. ■ Monitor patients with biliary tract disease for worsening of symptoms. ■ Monitor patients with a history of seizure disorders for worsening seizure control.

Patient Education:

Avoid alcohol or other CNS depressants (e.g., antihistamines, diazepam [Valium]) for 24 hours after surgery. ■ Blurred vision, dizziness, drowsiness, or light-headedness may occur; request assistance with ambulation. ■ Do not perform tasks requiring mental alertness (e.g., driving, operating hazardous machinery, signing legal documents) until day after surgery or longer.

Maternal/Child:

Use during pregnancy only when clearly needed; benefit must justify risk to fetus.

Remifentanil is not recommended for use in pregnant women during or immediately before labor when other analgesic techniques are more appropriate. ■ Use during labor and delivery may produce respiratory depression and a physiologic effect in neonates. Closely monitor neonates exposed to remifentanil during labor and delivery for signs of excessive sedation and respiratory depression. May also prolong labor by reducing the strength, duration, and frequency of contractions. ■ Prolonged use of opioid analgesics during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life threatening if not recognized and treated. ■ Other fentanyl analogs are secreted in breast milk; remifentanil not yet studied. Use caution during breast-feeding. ■ Monitor infants exposed to remifentanil through breast milk for excess sedation and respiratory depression. Withdrawal symptoms can occur in breast-fed infants when maternal administration of an opioid analgesic is stopped or when breast-feeding is stopped. ■ Safety and efficacy as an analgesic agent for use in the maintenance of general anesthesia in outpatient and inpatient pediatric surgery have been established. ■ Has not been studied in pediatric patients for use in the immediate postoperative period or for use as a component of monitored anesthesia care.

Elderly:

See Dose Adjustments. Increased sensitivity to effects. Clearance reduced by 25%, but blood concentrations fall rapidly after remifentanil is discontinued. Incidence of hypotension may be increased; nausea and vomiting may be decreased.

DRUG/LAB INTERACTIONS

Concomitant use of remifentanil with **benzodiazepines** (e.g., diazepam [Valium], midazolam [Versed]) and other **CNS depressants** (e.g., sedative/hypnotics, anxiolytics, tranquilizers, muscle relaxants, general anesthetics, antipsychotics, other opioids, alcohol) may result in profound sedation, respiratory depression, coma, and death. Hypotension can also occur. ■ Serotonin syndrome has been reported with the concomitant use of opioids, including remifentanil, and other **drugs that affect the serotonergic neurotransmitter system** (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin and norepinephrine reuptake inhibitors [SNRIs], tricyclic antidepressants [TCAs], triptans, 5-HT_3 receptor antagonists, mirtazapine, trazodone, tramadol, MAO inhibitors, linezolid, and intravenous methylene blue). Careful observation, particularly during treatment initiation and dose adjustment, is required with concomitant use. ■ Severe and unpredictable potentiation of **MAO inhibitors** (e.g., selegiline [Eldepryl], phenelzine [Nardil], tranylcypromine [Parnate], linezolid [Zyvox]) has been reported. MAO inhibitor interactions may manifest as serotonin syndrome or opioid toxicity (e.g., respiratory depression, coma). Use of remifentanil is not recommended for patients taking MAO inhibitors or within 14 days of stopping such treatment. ■ **Mixed agonist/antagonist analgesics and partial agonists** (e.g., buprenorphine [Buprenex], butorphanol [Stadol], nalbuphine, pentazocine [Talwin]) may reduce the analgesic effect of remifentanil and/or precipitate withdrawal symptoms. Avoid concomitant use. If concomitant use is warranted, observe patient carefully, particularly during treatment initiation and dose adjustment. Discontinue remifentanil if patient is not responding appropriately to treatment. ■ Respiratory depression increased and prolonged with **other concurrent anesthetics** (e.g., N_2O, propofol, isoflurane). ■ Nonspecific **esterases in blood products** may inactivate remifentanil. ■ Clearance is not altered by concomitant use of **thiopental, isoflurane, propofol, or temazepam** (Restoril) during anesthesia.

SIDE EFFECTS

The most common adverse reactions are bradycardia, hypotension, respiratory depression, and skeletal muscle rigidity. Other reported reactions include agitation, apnea, chills, constipation, dizziness, fever, flushing, headache, hypertension, hypoxia, nausea, pain at IV site, postoperative pain, pruritus, shivering, sweating, tachycardia, vomiting, warm sensation. Serious adverse reactions include biliary tract disease, bradycardia, hypotension, respiratory depression in spontaneously breathing patients, seizures, serotonin syndrome, and skeletal muscle rigidity. Many other side effects have been reported in a small number of patients.

Post-Marketing:

Anaphylaxis, asystole, serotonin syndrome.

Overdose:

Atypical snoring; bradycardia; circulatory depression; cold, clammy skin; death; hypotension; partial or complete airway obstruction; pinpoint pupils of eyes; pulmonary edema; respiratory depression; skeletal muscle flaccidity; somnolence progressing to stupor or coma.

ANTIDOTE

Keep physician informed of all side effects. Minor side effects will be tolerated or treated symptomatically. Major side effects or overdose may be life threatening and must be treated immediately. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Antagonized by opioid antagonists; short-acting opioid antagonists should be adequate (e.g., naloxone [Narcan]). Reversal of opioid effects may lead to acute pain and sympathetic hyperactivity. Respiratory depression in spontaneously breathing patients is usually managed by decreasing the rate of infusion by 50% or temporarily discontinuing remifentanil. Bradycardia and hypotension can be reversed by reducing the rate of infusion or the dose of concurrent anesthetics. Bradycardia is responsive to ephedrine or anticholinergic drugs such as atropine or glycopyrrolate. Hypotension may require IV fluids or catecholamines (e.g., ephedrine, epinephrine, norepinephrine). Treat excessive muscle rigidity during induction of anesthesia by administering a neuromuscular blocking agent (e.g., rocuronium [Zemuron]) and concurrent induction medications (e.g., propofol [Diprivan]). Treat excessive muscle rigidity in spontaneously breathing patients by decreasing the rate or by discontinuing remifentanil. In the case of life-threatening muscle rigidity, a rapid-onset neuromuscular blocking agent or naloxone may be administered. Resuscitate as necessary.

RESLIZUMAB BBW

(res-**LIZ**-ue-mab)

Cinqair
Interleukin-5 antagonist
Monoclonal antibody (IgG4_{κ})
pH 5.5

USUAL DOSE

Pretreatment:

Testing for eosinophilic phenotype indicated. See Maternal/Child.

Reslizumab:

3 mg/kg once every 4 weeks as an infusion over 20 to 50 minutes.

DOSE ADJUSTMENTS

No dose adjustments required based on age, gender, or race. Clinical studies have not been conducted to assess the effect of hepatic or renal impairment on the pharmacokinetics of reslizumab.

DILUTION

Supplied as a clear to slightly hazy/opalescent, colorless to slightly yellow solution in single-use vials containing 100 mg/10 mL (10 mg/mL). May contain a few translucent to white amorphous particulates. ***Do not shake.*** Aseptic technique required. Allow solution to reach room temperature. Withdraw the proper volume of reslizumab from the vial(s) based on the recommended weight-based dose and slowly add to a 50-mL infusion bag of NS. Gently invert to mix the solution. ***Do not shake.***

Filters:

Use of an infusion set with an in-line, low–protein-binding, 0.2-micron filter is required. **Compatible** with polyethersulfone (PES), polyvinylidene fluoride (PVDF), nylon, and cellulose acetate in-line infusion filters.

Storage:

Before use, refrigerate at 2° to 8° C (36° to 46° F) in original carton to protect from light. Do not freeze. ***Do not shake.*** Administer diluted solution immediately after preparation or may be refrigerated or kept at RT (up to 25° C [77° F]), protected from light, for up to 16 hours. Time between preparation and administration should not exceed 16 hours. If refrigerated before administration, allow the diluted solution to reach RT. Discard unused portion.

COMPATIBILITY

Manufacturer states, "Do not mix or dilute with other drugs. Do not infuse concomitantly in the same IV line with other agents." **Compatible** with polyvinylchloride (PVC) or polyolefin infusion bags and with polyethersulfone (PES), polyvinylidene fluoride (PVDF), nylon, and cellulose acetate in-line infusion filters.

RATE OF ADMINISTRATION

For IV infusion only. Do not administer as an IV push or bolus. Use of an infusion set with an in-line, low–protein-binding, 0.2-micron filter is required.

Administer a single dose as an infusion over 20 to 50 minutes. Infusion time varies depending on total volume to be infused based on weight-based dosing. After administration, flush the IV line with NS to ensure that all of the reslizumab has been administered.

ACTIONS

Inflammation is an important component in the pathogenesis of asthma. Multiple cell types and mediators are involved in inflammation. Reslizumab is a humanized interleukin-5 antagonist monoclonal antibody (IgG4, kappa). IL-5 is the major cytokine responsible for the growth and differentiation, recruitment, activation, and survival of eosinophils. Reslizumab binds to IL-5, inhibiting the bioactivity of IL-5. By inhibiting IL-5 signaling, reslizumab reduces the production and survival of eosinophils, one of the cell types implicated in the inflammation seen with asthma. Specific mechanism of action not definitively established. Following administration of reslizumab, reductions in blood eosinophil counts were observed and maintained through 52 weeks of treatment. There is minimal distribution into the extravascular tissues. Reslizumab is degraded by enzymatic proteolysis into small peptides and amino acids. Half-life is approximately 24 days.

INDICATIONS AND USES

Add-on maintenance treatment of patients with severe asthma who have an eosinophilic phenotype and are 18 years of age or older.

Limitations of use:

Not indicated for the treatment of other eosinophilic conditions. ■ Not indicated for the relief of acute bronchospasm or status asthmaticus.

CONTRAINDICATIONS

Known hypersensitivity to reslizumab or any of its excipients.

PRECAUTIONS

For IV use only. ■ Administered by or under the direction of a physician knowledgeable in its use and in a facility equipped to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. ■ Should not be used to treat acute asthma symptoms or acute exacerbations. Do not use to treat acute bronchospasm or status asthmaticus. ■ Malignant neoplasms have been reported. The majority were diagnosed within less than 6 months of exposure to reslizumab. The observed malignancies were diverse in nature and without clustering of any particular tissue type. ■ No clinical studies have been conducted to assess the reduction of maintenance corticosteroid doses following administration of reslizumab. Do not discontinue systemic or inhaled corticosteroids abruptly upon initiation of reslizumab therapy. Reductions in corticosteroid dose, if appropriate, should be gradual and under physician supervision. ■ Eosinophils may be involved in the immunologic response to some helminth infections. The effects of reslizumab on the immune response against parasitic infections are unknown. Patients with known parasitic infections were excluded from clinical studies. ■ A therapeutic protein, there is a potential for immunogenicity. ■ See Monitor.

Monitor:

Monitor for S/S of a hypersensitivity reaction during and following completion of the infusion. In clinical trials, anaphylaxis was observed during or within 20 minutes after completion of the infusion and was reported as early as the second dose of reslizumab. Manifestations included decreased oxygen saturation, dyspnea, skin and mucosal involvement (including urticaria), vomiting, and wheezing. ■ If a taper in the maintenance steroid dose is initiated, monitor for systemic withdrawal symptoms and/or conditions previously suppressed by systemic corticosteroid therapy. ■ Treat pre-existing helminth infections before initiating reslizumab. Discontinue treatment until infection resolves in patients who become infected during therapy and do not respond to anti-helminth treatment.

Patient Education:

Immediately report any S/S of a hypersensitivity reaction (e.g., chest discomfort, cough, dyspnea, postural dizziness, pruritus, rash, throat irritation, urticaria, wheezing) occurring during or after administration. ■ Does not treat acute asthma symptoms or acute exacerbations. Seek medical advice if asthma remains uncontrolled or worsens after initiation of treatment with reslizumab. ■ Malignancies have been reported. ■ Do not discontinue or reduce the dose of maintenance systemic or inhaled corticosteroids except under the direct supervision of a physician.

Maternal/Child:

Use during pregnancy only if clearly needed. In women with poorly or moderately controlled asthma, evidence demonstrates an increased risk of pre-eclampsia in the mother and an increased risk of prematurity, low birth weight, and smaller for gestational age in the neonate. The level of asthma control should be closely monitored in pregnant women and treatment adjusted as necessary to maintain optimal control. Monoclonal antibodies such as reslizumab cross the placental barrier. The potential effects on a fetus are likely to be greater during the second and third trimester of pregnancy. Consider the long half-life of reslizumab. ■ Use caution during breast-feeding; effects unknown. ■ Safety and effectiveness for use in pediatric patients 17 years of age or younger not established.

Elderly:

No overall differences in safety or effectiveness observed between younger patients and patients 65 years of age and older. No dose adjustment is necessary.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been performed. Population pharmacokinetics analyses indicate that concomitant use of either leukotriene antagonists (e.g., montelukast) or corticosteroids does not affect the pharmacokinetics of reslizumab.

SIDE EFFECTS

Oropharyngeal pain is the most common side effect. Less commonly reported adverse reactions include myalgia and transient creatine phosphokinase (CPK) elevations. Hypersensitivity reactions (including anaphylaxis) and malignancy are the most serious side effects.

ANTIDOTE

Keep the physician informed of all side effects. Most will be treated symptomatically. If a hypersensitivity reaction occurs, discontinue the infusion immediately and treat with oxygen, epinephrine, antihistamines (e.g., IV diphenhydramine), corticosteroids, albuterol, vasopressors (e.g., dopamine), and ventilation equipment as indicated. Symptoms of overdose were not noted in clinical trials. If overdose occurs, monitor patients for S/S of adverse effects. Resuscitate as necessary.

RETEPLASE RECOMBINANT

(**REE**-teh-place re-**KOM**-buh-nant)
Retavase, r-PA
Thrombolytic agent (recombinant)
pH 7 to 7.4

USUAL DOSE

Pretreatment:

Baseline assessment and studies indicated; see Monitor.

Administered concomitantly with heparin. Give a 5,000-unit IV bolus of heparin before the initial injection of reteplase, then give 10 units (10 mL) of reteplase as an IV injection. Follow with a 1,000 unit/hr continuous IV infusion of heparin for at least 24 hours. Give a second 10-unit bolus of reteplase 30 minutes after the first. See Dilution, Compatibility, and Rate of Administration. Aspirin is also used either during or following heparin treatment; an initial dose of 160 to 350 mg is followed by doses of 75 to 350 mg.

DOSE ADJUSTMENTS

The second bolus should not be given if serious bleeding in a critical location (e.g., intracranial, gastrointestinal, retroperitoneal, pericardial) occurs before it is due to be given.

DILUTION

Supplied in a kit with all components for reconstitution. Each kit contains a package insert and two of each of the following: single-use reteplase vials (10.8 units each), single-use diluent vials of SWFI (10 mL each), sterile 10-mL syringes with 20-gauge needles attached, sterile dispensing pins, sterile 20-gauge needles for administration, and alcohol swabs. Withdraw diluent with 20-gauge needle. Discard needle and put dispensing pin on syringe of diluent. Transfer diluent to vial of reteplase. Pin and syringe should remain in place while vial is swirled to dissolve reteplase. ***Do not shake.*** When completely dissolved, withdraw 10 mL reconstituted solution into the syringe (vials are 0.7 mL overfilled). Remove dispensing pin and replace with a 20-gauge needle for administration.

Storage:

Kit should remain sealed to protect contents from light. Store at 2° to 25° C (36° to 77° F). Do not use beyond expiration date. Contains no preservatives; should be reconstituted immediately before use, but may be stored at room temperature if used within 4 hours. Discard all unused solution and supplies.

COMPATIBILITY

Manufacturer states, "Should be given via an IV line in which no other medication is being simultaneously injected or infused. No other medication should be added to the injection solution containing reteplase. **Incompatible** with heparin; do not administer heparin in the same IV line unless the line is flushed through with NS or D5W before and after reteplase."

RATE OF ADMINISTRATION

Heparin:

First 1,000 units over 1 minute. After this test dose, the balance of 4,000 units may be given over 1 minute. Follow with an infusion of 1,000 units/hr.

Reteplase:

A single dose evenly distributed over 2 minutes. To avoid **incompatibilities** and ensure delivery of both doses, be sure to flush line with a minimum of 30 to 50 mL NS or D5W before and after each injection.

ACTIONS

A recombinant plasminogen activator. Exerts its thrombolytic action by generating plasmin from plasminogen through a specific process. Plasmin then degrades the fibrin matrix of the thrombus. Potency is expressed in units that are specific to reteplase. With therapeutic doses, a decrease in circulating fibrinogen makes the patient susceptible to bleeding. Onset of action is prompt, effecting patency of the vessel within 90 minutes in most patients. The FDA has allowed the manufacturer to claim superiority over alteplase at achieving patency within 90 minutes. Prompt opening of arteries increases probability of improved cardiac function. Half-life is 13 to 16 minutes. Cleared from the plasma by the liver and kidneys. Mean fibrinogen level should return to baseline value within 48 hours.

INDICATIONS AND USES

Management of acute myocardial infarction (AMI) in adults for the improvement of ventricular function following AMI, the reduction of the incidence of congestive failure, and the reduction of mortality associated with AMI. Treatment should begin as soon as possible after the onset of symptoms of AMI. ■ Current AHA and JAMA recommendations identify thrombolytic agents as Class I therapy in patients younger than 70 years with recent onset of chest pain (within 6 hours) consistent with AMI and at least 0.1 mV of ST segment elevation in at least two ECG leads. Use in all other patients based on age, accurate diagnosis, and time from onset of chest pain.

CONTRAINDICATIONS

Active internal bleeding, arteriovenous malformation or aneurysm, bleeding diathesis, history of cerebral vascular accident, intracranial or intraspinal surgery or trauma within 2 months, intracranial neoplasm, severe uncontrolled hypertension.

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use and with appropriate emergency drugs and diagnostic and laboratory facilities available. ■ Reperfusion arrhythmias occur frequently (e.g., sinus bradycardia, accelerated idioventricular rhythm, PVCs, ventricular tachycardia); have antiarrhythmic medications available at bedside. ■ A greater alteration of hemostatic status than with heparin. Strict bed rest indicated to reduce risk of bleeding. Use extreme care with the patient; avoid any excessive or rough handling or pressure (including too-frequent BPs); avoid invasive procedures (e.g., arterial puncture, venipuncture, IM injection). If these procedures are absolutely necessary, use extreme precautionary methods (use radial artery instead of femoral; small-gauge catheters and needles, and sites that are easily observed and compressible where bleeding can be controlled; avoid handling of catheter sites, and use extended pressure application of up to 30 minutes). Minor bleeding occurs often at catheter insertion sites. Avoid use of razors and toothbrushes. ■ Use extreme caution and weigh risks against anticipated benefits in the following situations: recent major surgery (e.g., coronary artery bypass graft, obstetric delivery, organ biopsy), previous puncture of noncompressible vessels (e.g., jugular, subclavian), cerebrovascular disease, recent GI or GU bleeding, recent trauma, hypertension (e.g., systolic BP equal to or greater than 180 mm Hg and/or diastolic BP equal to or greater than 110 mm Hg), high likelihood of left heart thrombus (e.g., mitral stenosis with atrial fibrillation), acute pericarditis, subacute bacterial endocarditis, hemostatic defects including those secondary to severe hepatic or renal disease, severe hepatic or renal dysfunction, pregnancy, diabetic hemorrhagic retinopathy or other hemorrhagic ophthalmic conditions, septic thrombophlebitis or occluded AV cannula at a seriously infected site, advanced age, patients currently receiving oral anticoagulants (e.g., warfarin [Coumadin]), any other condition in which bleeding constitutes a significant hazard or would be particularly difficult to manage because of its location. ■ Simultaneous therapy with continuous infusion of heparin is used to reduce the risk of rethrombosis. Markedly increases risk of bleeding. ■ Standard treatment for myocardial infarction continues simultaneously with reteplase therapy except if temporarily contraindicated (e.g., arterial blood gases unless absolutely necessary). ■ No experience with patients receiving repeat courses of reteplase. ■ Cholesterol embolization has been reported and may be fatal.

Monitor:

Best to establish separate IV lines for reteplase and heparin. If not appropriate, be sure to flush the IV line before and after each injection of reteplase. ■ Baseline ECG, CPK, and clotting studies (TT, PTT, CBC, fibrinogen level, platelets) and baseline assessment (patient condition, pain, hematomas, petechiae, or recent wounds) should be completed before administration. Type and cross-match may also be ordered. ■ Monitor ECG continuously, and record strips with greatest ST segment elevation initially and every 15 minutes for at least 4 hours. A 12-lead ECG is indicated when therapy is complete. ■ Maintain strict bed rest; monitor the patient carefully and frequently for anginal pain and signs of bleeding; observe catheter sites at least every 15 minutes and apply pressure dressings to any recently invaded site; watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, muscle weakness; do neuro checks every hour. Continue until normal clotting function returns. ■ Watch for extravasation. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Compliance with all measures to minimize bleeding (e.g., strict bed rest) is very important. ■ Avoid use of razors, toothbrushes, and other sharp items. ■ Use caution while moving to avoid excessive bumping. ■ Report all episodes of bleeding and apply local pressure if indicated. Expect oozing from IV sites.

Maternal/Child:

Category C: has resulted in hemorrhage leading to spontaneous abortions in rabbits. Safety for use in pregnancy, breast-feeding, and pediatric patients not established.

Elderly:

See Indications and Precautions. ■ May have poorer prognosis following AMI or with pre-existing conditions that may increase the risk of intracranial bleeding. Select patients carefully to maximize benefits.

DRUG/LAB INTERACTIONS

Interaction of reteplase with other cardioactive drugs has not been studied. Risk of bleeding may be increased by **any medicine that affects blood clotting,** including anticoagulants (e.g., heparin, warfarin); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel, dipyridamole, glycoprotein GPIIb/IIIa receptor antagonists, valproic acid). Concurrent use not recommended with the exception of heparin and aspirin (in AMI) to reduce the risk of rethrombosis. If concurrent or subsequent use is indicated (e.g., management of acute coronary syndrome, percutaneous coronary intervention), monitor PT and aPTT closely. ■ **Coagulation tests will be unreliable;** specific procedures can be used; notify the lab of reteplase use.

SIDE EFFECTS

Bleeding is most common: internal (GI tract, GU tract, intracranial, respiratory, or retroperitoneal sites), epistaxis, gingival, and superficial or surface bleeding (venous cutdowns, arterial punctures, sites of recent surgical intervention). Reperfusion arrhythmias are common; other serious arrhythmias may occur. A few hypersensitivity reactions, as well as fever, hypotension, nausea, and vomiting, have occurred. Cholesterol embolism has been reported and may be fatal. Clinical S/S may include acute renal failure, gangrenous digits, hypertension, infarctions (e.g., bowel, cerebral, myocardial, or spinal cord), pancreatitis, “purple toe” syndrome, renal artery occlusion.

ANTIDOTE

Notify physician of all side effects. Note even the most minute bleeding tendency. Oozing at IV sites is expected. Control minor bleeding by local pressure. For severe bleeding in a critical location, discontinue second dose of reteplase if it has not been given and any heparin therapy immediately. Whole blood, packed RBCs, cryoprecipitate, fresh frozen plasma, platelets, desmopressin, tranexamic acid, and aminocaproic acid may all be indicated. Topical preparations of aminocaproic acid may stop minor bleeding. Consider protamine if heparin has been used. Treat bradycardia with atropine, reperfusion arrhythmias with lidocaine or procainamide; VT or VF may require cardioversion. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary. Discontinue therapy if any symptoms of cholesterol embolism occur.

Rh$_o$(D) IMMUNE GLOBULIN INTRAVENOUS (HUMAN) BBW

(ih-**MUNE** **GLAW**-byoo-lin **IN**-trah-ve-nes)
Rh$_o$(D)-IGIV, Rhophylac, WinRho SDF
Immunizing agent (passive)
Platelet count stimulator
pH 6.5 to 7.6

USUAL DOSE (International units [IU])

Pregnancy, predelivery:

Rhophylac and WinRho SDF:

Confirm Rh$_o$(D)-negative status of patient. May be given IV or IM. 1,500 IU (300 mcg) at 28 weeks’ gestation. If ***WinRho SDF*** is administered early in the pregnancy, it should be repeated at 12-week intervals to maintain an adequate level of passively acquired anti-Rh.

Pregnancy, postdelivery:

Confirm Rh$_o$(D)-negative status of patient. May be given IV or IM. Administer as soon as possible after delivery of a confirmed Rh_0(D)-positive baby. Usually given no later than 72 hours postdelivery. If the Rh status of the infant is unknown at 72 hours, administer to the mother at that time. Should be given as soon as possible up to 28 days after delivery. This second dose postdelivery (first dose given predelivery; see above) can reduce treatment failure.

Rhophylac:

1,500 IU (300 mcg).

WinRho SDF:

600 IU (120 mcg).

Postabortion, amniocentesis (after 34 weeks' gestation), or any other manipulation late in pregnancy (after 34 weeks' gestation):

Confirm Rh_0(D)-negative status of patient. May be given IV or IM. Administer immediately after abortion or procedure associated with increased risk of Rh isoimmunization. Must be given within 72 hours. One-half of a dose (a mini-dose [IM product]) may be given if a pregnancy terminates before 13 weeks' gestation, administration within 3 hours is preferred. According to the literature, this mini-dose can provide 100% effectiveness in preventing Rh immunization.

Rhophylac:

1,500 IU (300 mcg).

WinRho SDF:

600 IU (120 mcg).

Postamniocentesis before 34 weeks' gestation or after chorionic villus sampling:

Confirm Rh_0(D)-negative status of patient. May be given IV or IM. ***Rhophylac or WinRho SDF:*** 1,500 IU (300 mcg) immediately after the procedure. Repeat ***WinRho SDF*** every 12 weeks during the pregnancy.

Threatened abortion:

Confirm Rh_0(D)-negative status of patient. May be given IV or IM. ***Rhophylac or WinRho SDF:*** 1,500 IU (300 mcg) as soon as possible.

Transfusion or fetal hemorrhage:

Confirm Rh_0(D)-negative status of patient. May be given IV or IM. Administer within 72 hours of an incompatible event involving Rh_0(D)-positive blood such as exposure to incompatible blood transfusions (Rh+ whole blood or Rh+ red blood cells) or massive fetal hemorrhage.

Rhophylac:

Give 100 IU (20 mcg) per each 2 mL transfused blood or per 1 mL erythrocyte concentrate. In cases of known or suspected excessive feto-maternal hemorrhage, the number of fetal red blood cells in the maternal circulation should be determined. If testing is not feasible and excessive feto-maternal hemorrhage cannot be excluded, administer a dose of 1,500 IU (300 mcg).

WinRho SDF:

Give up to 3,000 IU (600 mcg) every 8 hours IV or 6,000 IU (1,200 mcg) every 12 hours IM until the total dose is administered. Total IV dose is 45 IU (9 mcg) for every milliliter of Rh+ whole blood exposure or 90 IU (18 mcg) for every milliliter of Rh+ red blood cell exposure. Total IM dose is 60 IU (12 mcg) for every milliliter of Rh+ whole blood exposure or 120 IU (24 mcg) for every milliliter of Rh+ red blood cell exposure.

Treatment of immune thrombocytopenic purpura (ITP); Adults and pediatric patients:

WinRho SDF:

Confirm Rh_o(D)-positive status of patient. Must be given IV. Hemoglobin should be greater than 10 Gm/dL. Give 250 IU/kg (50 mcg/kg) of body weight as the initial dose. May be given as a single dose or divided in half and given on 2 consecutive days. If response to the initial dose is adequate, maintenance doses of 125 to 300 IU/kg (25 to 60 mcg/kg) may be given. If response to the initial dose is inadequate, see Dose Adjustments. Dose and frequency based on patient's clinical response (e.g., RBC, hemoglobin, reticulocyte levels, and platelet counts); see Dose Adjustments.

PEDIATRIC DOSE

Treatment of ITP:

WinRho SDF:

See Usual Dose and Dose Adjustments.

DOSE ADJUSTMENTS (International units [IU])

Pregnancy and obstetrical conditions:

WinRho SDF suggests protection must be maintained throughout pregnancy once Rh_o(D) immune globulin is administered. Level of passively acquired anti-Rh_o(D) should not fall below levels required to prevent an immune response to Rh_o(D)-positive blood. Additional doses should be given every 12 weeks during pregnancy and at delivery unless the previous dose was administered within 3 weeks and there is less than 15 mL of fetomaternal red blood cell hemorrhage during delivery.

Suppression of Rh isoimmunization:

Rhophylac and WinRho SDF:

A large fetomaternal hemorrhage may cause an incorrect evaluation by standard tests of the amount of Rh_o(D) IGIV required. Assess the amount of hemorrhage and adjust dose accordingly.

Treatment of ITP: Adults and pediatric patients:

WinRho SDF:

If the hemoglobin level is less than 10 Gm/dL before or after the initial dose, reduce the initial dose and/or maintenance doses to 125 to 200 IU (25 to 40 mcg)/kg to minimize the risk of increasing the severity of anemia in the patient. ■ In patients with adequate platelet response to the initial dose, adjust maintenance doses based on platelet and hemoglobin levels. ■ If response to the initial dose is inadequate, adjust subsequent doses as follows:

> Hemoglobin above 10 Gm/dL: redose with 250 to 300 IU (50 to 60 mcg)/kg.
> Hemoglobin is 8 to 10 Gm/dL: redose with 125 to 200 IU (25 to 40 mcg)/kg.
> Hemoglobin below 8 Gm/dL: use with caution; may increase severity of anemia.

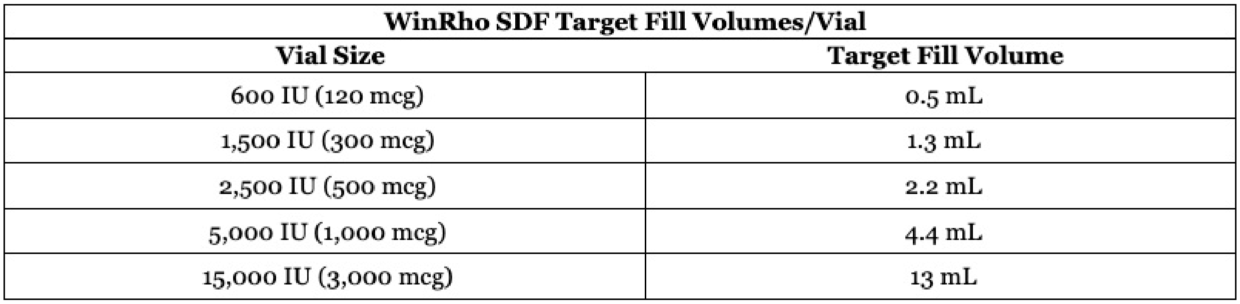
DILUTION (International units [IU])

Rhophylac:

Available in a prefilled 2-mL syringe containing 1,500 IU (300 mcg) for single-dose use. Bring to room or body temperature before use.

WinRho SDF:

Available as a ready-to-use liquid. 5 IU equals 1 mcg. Withdraw the entire contents of the vial to obtain the labeled dose. If indicated, calculate a partial dose, then discard the excess from the syringe. The target fill volume of each vial is included in the following chart.



WinRho SDF Target Fill Volumes/Vial	
Vial Size	**Target Fill Volume**
600 IU (120 mcg)	0.5 mL
1,500 IU (300 mcg)	1.3 mL
2,500 IU (500 mcg)	2.2 mL
5,000 IU (1,000 mcg)	4.4 mL
15,000 IU (3,000 mcg)	13 mL

Storage:

Rhophylac:

Refrigerate syringes before use. Protect from light. Should not be used after expiration date. Discard unused product in syringe. ***WinRho SDF:*** Store unopened vials in refrigerator. Note expiration date. Do not freeze. Discard unused portion.

COMPATIBILITY

Rhophylac:

Compatibility information not available from manufacturer; consult a pharmacist.

WinRho SDF:

Manufacturer states, "Should be administered separately from other drugs." Dilute only with NS.

RATE OF ADMINISTRATION

Rhophylac:

A single dose as a slow IV injection.

WinRho SDF:

A single dose as an IV injection over 3 to 5 minutes.

ACTIONS (International units [IU])

Rhophylac and WinRho SDF:

Specialty immunoglobulins. A gamma globulin (IgG) fraction containing antibodies to the Rh_o(D) antigen (D Antigen). Reduces the incidence of Rh immunization of an Rh_o(D)-negative mother by an Rh_o(D)-positive infant before, during, and after delivery; reduces the likelihood of hemolytic disease in an Rh_o(D)-positive infant in present and future pregnancies. Has also been shown to increase platelet counts in nonsplenectomized Rh_o(D)-positive patients with immune thrombocytopenic purpura (ITP). A 1,500-IU vial or syringe contains 300 mcg of anti-Rh_o(D), which can effectively suppress the immunizing potential of approximately 15 to 17 mL of Rh_o(D)-positive blood cells, and, in addition, contains 25 to 40 mg of nonspecific gammaglobulin. Pooled from source plasma selected for high titers of Rh_o(D) antibody. Purified and standardized by several methods (e.g., solvent-detergent viral inactivation process to decrease the possibility of transmission of blood-borne pathogens [e.g., HIV, hepatitis]). Similar to native IgG that normally circulates in human plasma.

Rhophylac:

Is thimerosal free, mercury free, and latex free. Contains albumin as a stabilizer. Half-life is 12 to 20 days. Anti-D IgG titers were measurable up to 9 weeks after injection.

WinRho SDF:

Has also been shown to increase platelet counts in nonsplenectomized Rh_o(D)-positive patients with immune thrombocytopenic purpura (ITP). Platelet counts usually begin to rise in 1 to 2 days with peak effect in 7 to 14 days. Some effects last about 30 days. Contains 25 to 40 mg of nonspecific gammaglobulin. The liquid form contains maltose as a stabilizer; the lyophilized powder is stabilized with glycine, NaCl, and polysorbate

80. Half-life is 24 days. Crosses the blood-brain barrier.

INDICATIONS AND USES

Rhophylac and WinRho SDF:

Suppression of Rh isoimmunization in nonsensitized Rh_o(D)-negative women during the normal course of pregnancy, within 72 hours after spontaneous or induced abortions, amniocentesis, chorionic villus sampling, ruptured tubal pregnancy, abdominal trauma or transplacental hemorrhage, unless the blood type of the fetus or father is known to be Rh_o(D)-negative. ■ Suppression of Rh isoimmunization in Rh_o(D)-negative female pediatric patients and female adults in their childbearing years transfused with Rh_o(D)-positive red blood cells or blood components containing Rh_o(D)-positive RBCs.

WinRho SDF:

Treatment of nonsplenectomized Rh_o(D)-positive pediatric patients with acute or chronic immune thrombocytopenic purpura (ITP), adults with chronic ITP, or pediatric patients and adults with ITP secondary to HIV infection in clinical situations requiring an increase in platelet counts to prevent excessive hemorrhage.

CONTRAINDICATIONS

Rhophylac and WinRho SDF:

All uses:

History of a prior severe hypersensitivity reaction to human immune globulin preparations or their components (***Rhophylac*** contains albumin, ***WinRho SDF*** may contain thimerosal); patients with isolated IgA deficiency or pre-existing IgA antibodies (benefits must outweigh risks; risk of anaphylaxis is greater).

Suppression of Rh isoimmunization in pregnancy:

For suppression of Rh isoimmunization in the mother. ***Do not administer to the infant.*** Not recommended for use in Rh_o(D)-negative individuals shown to be Rh immunized by standard screening tests.

WinRho SDF:

Treatment of ITP:

Not recommended for use in Rh_o(D)-negative or splenectomized individuals.

PRECAUTIONS

All uses:

Confirm vial or syringe label—must state for IV or IV/IM use; several similar products are for IM use only (e.g., RhoGam). ■ May risk transmission of infectious agents (e.g., hepatitis, HIV, possibly the Creutzfeldt-Jakob disease [CJD] agent); see Actions. ■ May contain trace amounts of anti-A, anti-B, anti-C, and anti-E blood group antibodies. ■ Use caution and weigh benefit versus risk in patients with known hypogammaglobulinemia or selective IgA deficiency; risk of severe hypersensitivity reactions or anaphylaxis is increased. ■ Not intended for use in Rh+ individuals (with the exception of ***WinRho SDF*** in the treatment of ITP). ■ Use with caution and monitor renal function in patients at risk for renal insufficiency. IGIV products have been reported to produce renal dysfunction in patients who are predisposed to acute renal failure or in those who have renal insufficiency. Most reports involve products that contain sucrose as a stabilizer. WinRho SDF does not contain sucrose.

Suppression of Rh isoimmunization in pregnancy:

More than 1 dose of Rh_0(D) immune globulin may be required. A fetal RBC count can be done on maternal blood to determine the required dose. ■ If a large fetomaternal hemorrhage occurs late in pregnancy or after delivery, Rh_0(D) IGIV should be administered in sufficient doses if there is any doubt about the mother's blood type (e.g., presence of passively administered anti-Rh_0(D) in maternal or fetal blood [positive Coombs' test]). ■ See Monitor. ■ Manufacturer recommends IM or IV use. Another source recommends IM injection when Rh_0(D) is used as an immunizing agent. ■ Not effective in Rh_0(D)-negative females who have already been sensitized to the Rh_0(D) erythrocyte factor; however, if administered, the risk of side effects is not increased.

Treatment of ITP:

IV route required for ITP. ■ Rare cases of intravascular hemolysis have been reported. Usually occurs within 4 hours of administration. Complications may include clinically compromising anemia and multisystem organ failure, including ARDS. Fatalities have occurred. Serious complications, including severe anemia, acute renal insufficiency, renal failure, and DIC, have also been reported. Even if previous infusions have been uneventful, intravascular hemolysis and its complications may occur with subsequent infusions. ■ If the hemoglobin level is less than 8 Gm/dL, use with extreme caution; may increase severity of anemia.

Monitor:

All uses:

See Precautions. ■ Observe patient for at least 20 to 30 minutes after injection.

Suppression of Rh isoimmunization in pregnancy:

Maintain accurate records of Rh factor and Rh_0(D)-IGIV. ■ Obtain CBC and other appropriate lab work based on procedure or situation. ■ Monitor vital signs if indicated.

Treatment of ITP:

Obtain baseline RBC, hemoglobin, reticulocyte levels, and platelet counts. Monitor during therapy to determine clinical response. ■ Given to Rh_0(D)-positive patients in this situation, interaction with RBC usually causes some degree of RBC hemolysis; observe carefully. Monitor for S/S of intravascular hemolysis (back pain, chills, fever, hemoglobinuria) for at least 8 hours after infusion. Perform a dipstick urinalysis at baseline, at 2 and 4 hours, and before the end of the monitoring period. ■ Monitor for complications of intravascular hemolysis (IVH), including clinically compromising anemia (decreased hemoglobin, hypotension, pallor, and tachycardia), acute renal insufficiency (anuria, dyspnea, edema, or oliguria), or DIC (increased bruising and prolongation of bleeding or clotting time). ■ If S/S of IVH or its complications occur, lab tests should be performed to confirm the diagnosis. Tests include but are not limited to CBC with platelets, haptoglobin, plasma hemoglobin, urine dipstick, BUN, SCr, LDH, direct and indirect bilirubin, and DIC-specific tests (e.g., d-dimer, fibrin degradation products [FDP], fibrin split products [FSP]). ■ If transfusion is required, use Rh$_o$(D)-negative RBCs to avoid exacerbating ongoing IVH. Platelet products may contain RBCs; use caution if platelets from an Rh$_o$(D)-positive donor are used.

Patient Education:

Report S/S of a hypersensitivity reaction (e.g., feeling of fainting, hives, itching, tightness in the chest, wheezing). ■ Report feelings of dizziness, tiredness, weakness. ***ITP:*** May cause a considerable drop in hemoglobin; follow-up testing important. ■ Immediately report symptoms of back pain, chills, decreased urine output, discolored urine or hematuria, fever, sudden weight gain, fluid retention/edema, and/or shortness of breath. May indicate onset of intravascular hemolysis (IVH).

Maternal/Child:

Category C: use only if clearly needed. ■ Rhophylac is not secreted in breast milk. Specific information is not available for WinRho SDF on safety during breast-feeding. ■ For the suppression of Rh isoimmunization in the mother; do not administer to the infant.

Elderly:

When used for treatment of ITP, fatal outcomes associated with IVH and its complications occurred most frequently in patients over 65 years of age with comorbid conditions.

DRUG/LAB INTERACTIONS

Interaction with other drugs has not been evaluated. ■ Antibodies contained in Rh$_o$(D) immune globulin may interfere with the body's immune response to certain **live virus vaccines.** Do not administer live virus vaccines (e.g., measles, mumps, polio, or rubella) for at least 3 months after Rh$_o$(D) administration. ■ Trace amounts of anti-A, anti-B, anti-C, and anti-E blood group antibodies may be detectable in **direct and indirect antiglobulin (Coombs') tests** following treatment with Rh$_o$(D). ■ May affect outcomes of **blood typing and antibody testing** in neonates. ■ The liquid formulation of WinRho SDF contains maltose, which may give **falsely high blood glucose levels** with certain types of blood glucose testing systems. Only testing systems that are glucose specific should be used to monitor blood glucose levels in patients receiving maltose-containing parenteral products such as WinRho SDF.

SIDE EFFECTS

All uses:

Abdominal or back pain, arthralgias, asthenia, chills, diarrhea, dizziness, fever, headache, hyperkinesia, hypertension, hypotension, increased LDH, pruritus, rash, somnolence, and sweating. Hypersensitivity reactions, including anaphylaxis, have been reported rarely. Made from human plasma donors, transmission of selected diseases possible but not probable; see Precautions.

Suppression of Rh isoimmunization in pregnancy:

Side effects are infrequent in Rh_o(D)-negative individuals. Only a few women have had treatment failures resulting in development of Rh_o(D) antibodies.

ITP:

Destruction of Rh_o(D) red cells resulting in decreased hemoglobin (range was 0.4 to 6.1 Gm/dL). IVH (back pain, shaking chills, hemoglobinuria), acute onset and exacerbation of anemia, and renal insufficiency have been reported in Rh_o(D)-positive patients. Has rarely resulted in death.

ANTIDOTE

Keep physician informed of side effects; may require symptomatic treatment. Discontinue immediately if a hypersensitivity reaction occurs; treat as indicated (e.g., maintain airway, administer fluids, oxygen, epinephrine, diphenhydramine, corticosteroids [e.g., dexamethasone (Decadron)]). ***ITP:*** Treatment may have to be discontinued if drop in hemoglobin is too severe. Transfusion may be required.

RIFAMPIN

(rih-**FAM**-pin)
Rifadin
Antibacterial (Rifamycin)
Antitubercular agent
pH 7.8 to 8.8

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Precautions and Monitor.

Dose and schedule may vary depending on treatment regimen selected. IV doses are the same as oral. Use oral dose form as soon as practical.

Tuberculosis (adults and pediatric patients 15 years of age or older):

10 mg/kg once a day when used in conjunction with other antitubercular agents in a

daily regimen, or 10 mg/kg not to exceed 600 mg/dose two or three times a week when used in an intermittent multiple-drug regimen. Do not exceed 600 mg/day. Prescribed concurrently with other antitubercular drugs (e.g., ethambutol [Myambutol], isoniazid [INH], pyrazinamide, or streptomycin). Consult current CDC guidelines for suggested treatment regimens.

Meningococcal carriers:

600 mg every 12 hours for 2 days.

PEDIATRIC DOSE

Tuberculosis:

10 to 20 mg/kg of body weight once a day when used in conjunction with other antitubercular agents in a daily regimen, or two or three times a week when used in an intermittent multiple-drug regimen. Do not exceed 600 mg/day. Prescribed concurrently with other antitubercular drugs (e.g., ethambutol [Myambutol], isoniazid [INH], pyrazinamide, or streptomycin).

Meningococcal carriers:

Under 1 month of age: 5 mg/kg every 12 hours for 2 days. ***Over 1 month of age:*** 10 mg/kg every 12 hours for 2 days. Do not exceed 600 mg/dose.

DOSE ADJUSTMENTS

There are no dose adjustments provided in the manufacturer’s prescribing information for patients with impaired hepatic function; use caution. ■ No dose adjustment is necessary in impaired renal function; serum concentrations do not change. ■ See Drug/Lab Interactions.

DILUTION

Each 600-mg vial must be initially diluted in 10 mL of SWFI (60 mg/mL). Swirl gently to dissolve. Withdraw desired dose and further dilute in 500 mL or 100 mL of D5W or NS; see Storage.

Storage:

Store vials at CRT. Avoid excessive heat (temperatures above 40° C [104° F]). Protect from light. Reconstituted solution stable at RT for 30 hours. Use solution diluted in D5W within 8 hours; solution diluted in NS stable for 6 hours.

COMPATIBILITY

Manufacturer states, “May form a precipitate with diltiazem at the **Y-site.**” Infusion solutions other than D5W or NS are not recommended.

RATE OF ADMINISTRATION

A single dose diluted in 500 mL equally distributed as an infusion over 3 hours. In selected situations a single dose diluted in 100 mL may be administered over 30 minutes.

ACTIONS

A semi-synthetic antibiotic derivative of rifamycin. Has bactericidal activity in vitro against slow and intermittently growing *Mycobacterium tuberculosis* organisms and has been shown to be active against most strains of *Neisseria meningitidis* and *Mycobacterium tuberculosis*. Inhibits bacterial DNA-dependent RNA polymerase activity in susceptible *M. tuberculosis* organisms but does not inhibit the mammalian enzyme. Rapidly distributed throughout the body and present in many organs and body fluids, including CSF. 80% protein bound. Metabolized in the liver. Undergoes enterohepatic circulation. Excreted in bile and urine. Half-life following repeated dosing is 3 to 4 hours. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment or retreatment of all forms of tuberculosis when the drug cannot be taken by mouth. ■ Treatment of asymptomatic carriers of *Neisseria* meningitis. Not indicated for treatment of meningococcal infection because of rapid emergence of resistant meningococci.

Unlabeled uses:

Used in combination with other agents in the treatment of certain atypical mycobacterial infections (e.g., *Mycobacterium avium*). ■ Used in combination with other antistaphylococcal agents to treat serious staphylococcal infections.

CONTRAINDICATIONS

Hypersensitivity to rifampin or any of its components or to any rifamycins. ■ Contraindicated in patients receiving ritonavir-boosted saquinavir; risk for severe hepatocellular toxicity is increased. ■ Concomitant use with atazanavir, darunavir, fosamprenavir, saquinavir, and tipranavir; see Drug/Lab Interactions. ■ Contraindicated in patients receiving praziquantel since therapeutically effective blood levels of praziquantel may not be achieved. In patients receiving rifampin who need immediate treatment with praziquantel, alternative agents should be considered. If treatment with praziquantel is necessary, rifampin should be discontinued 4 weeks before administration of praziquantel. Treatment with rifampin can then be restarted 1 day after completion of praziquantel treatment.

PRECAUTIONS

For IV use only. Do not administer IM or SC. ■ Obtain cultures and susceptibility studies before starting therapy to confirm susceptibility of the organism to rifampin. Repeat studies periodically during therapy to monitor for the emergence of resistance. ■ Resistance can emerge rapidly; appropriate susceptibility tests should be performed in the event of persistent positive cultures. ■ Susceptibility tests also required before use as treatment for asymptomatic carriers of *Neisseria* meningitis. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, rifampin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Organisms resistant to rifampin are likely to be resistant to other rifamycins. ■ Hepatoxicity of hepatocellular, cholestatic, and mixed patterns has occurred. Severity ranged from asymptomatic elevations in liver enzymes, isolated jaundice/hyperbilirubinemia, and symptomatic self-limited hepatitis to fulminant liver failure and death. Risk of liver damage is markedly increased if impaired liver function is present and when rifampin is given with other hepatotoxic agents (e.g., isoniazid [INH], halothane). Discontinue rifampin if hepatic damage occurs or worsens. ■ Systemic hypersensitivity reactions may occur in patients taking rifampin. Manifestations of hypersensitivity (fever, laboratory abnormalities [including eosinophilia and liver abnormalities], and lymphadenopathy) may be present even without rash. If S/S occur, discontinue rifampin and administer supportive measures. ■ Cases of severe cutaneous adverse reactions (SCAR) such as Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN), acute generalized exanthematous pustulosis (AGEP), and drug reaction with eosinophilia and systemic symptoms (DRESS) syndrome have occurred. Discontinue rifampin immediately and institute appropriate therapy if S/S of severe cutaneous adverse reactions develop. ■ May cause vitamin K–dependent coagulation disorders and bleeding. Consider discontinuation if abnormal coagulation tests and/or bleeding occur. Supplemental vitamin K administration should be considered when appropriate. ■ May exacerbate porphyria. ■ Use with caution in patients with diabetes; diabetes management may be more difficult. ■ Not recommended for intermittent therapy; interruption of daily dosage regimen has resulted in rare renal hypersensitivity reactions when therapy was resumed. ■ Urine, feces, sputum, sweat, teeth, and tears may be colored red-orange. Soft contact lenses may be permanently stained. CSF may be light yellow. ■ Pseudomembranous colitis has been reported. May range from mild to life threatening. Consider in patients who present with diarrhea during or after treatment with rifampin.

Monitor:

Obtain baseline measurements of hepatic enzymes (e.g., ALT and AST), bilirubin, SCr, CBC, and platelet count. Routine lab monitoring in patients with normal baseline labs is generally not necessary. However, patients should be seen monthly and questioned about symptoms that may indicate adverse reactions. ■ Monitor liver function every 2 to 4 weeks in patients with pre-existing liver impairment. ■ Monitor for S/S and clinical/laboratory signs of liver injury, especially if treatment is prolonged or given with other hepatotoxic drugs. ■ Monitor coagulation tests during treatment (prothrombin time and other coagulation tests) in patients at risk for vitamin K deficiency (e.g., those with chronic liver disease, poor nutritional status, taking prolonged antibacterial drugs or anticoagulants). ■ Monitor blood glucose closely in patients with diabetes. ■ Notify physician immediately if flu-like symptoms develop; may be due to hepatotoxicity. ■ Monitor for S/S of hypersensitivity reaction (e.g., acute bronchospasm, angioedema, conjunctivitis, DRESS, elevated liver transaminases, fever, flu-like syndrome [aches, chills, chest pain, cough, dizziness, fatigue, headache, itching, muscle pain, nausea, palpitations, shortness of breath, sweats, syncope, vomiting, weakness], hypotension, neutropenia, rash, thrombocytopenia, urticaria). ■ Monitor for S/S of severe cutaneous adverse reactions. ■ Thrombocytopenia has occurred. Reversible if rifampin is discontinued as soon as purpura occurs. Cerebral hemorrhage has occurred when rifampin has been continued or resumed after the appearance of purpura. Contact physician immediately if purpura occurs. ■ Confirm patency of IV; avoid extravasation. Restart IV at a new site for any signs of inflammation or irritation. ■ Do all lab tests and affected radiology studies before daily dose of medication. ■ See Drug/Lab Interactions.

Patient Education:

Reliability of hormonal contraceptives may be affected; use of nonhormonal contraceptives recommended. ■ Do not take any other medication without medical advice. ■ Avoid use of alcohol, other hepatotoxic agents (e.g., acetaminophen, NSAIDs, phenothiazines, some antineoplastic agents, sulfonamides), or herbal products. ■ Review side effects with health care professional and promptly report abdominal pain, cough, darkened urine, itching, light-colored bowel movements, loss of appetite, malaise, nausea and vomiting, pain or swelling of the joints, rash with fever or blisters with or without peeling skin, shortness of breath, swollen lymph nodes, wheezing, or yellowish discoloration of the skin and eyes. ■ May cause discoloration (yellow, orange, red, brown) of feces, sputum, sweat, urine, tears, and teeth. ■ May permanently stain soft contact lenses. ■ Do not interrupt daily dosage regimen.

Maternal/Child:

Has teratogenic potential. Safety for use during pregnancy not established. Benefit must outweigh risk. See literature for best combinations with least known risk. ■ Administration during the last few weeks of pregnancy may cause postnatal hemorrhages in mother and infant; treatment with vitamin K may be required. ■ Closely monitor neonates of rifampin-treated mothers for adverse effects. ■ Discontinue breast-feeding if mother requires treatment. ■ Has been used in pediatric patients.

Elderly:

Differences in response between elderly and younger patients have not been identified. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

Interactions are numerous and potentially life threatening. Review of drug profile by pharmacist imperative. ■ Hepatotoxicity, hepatic encephalopathy, and death associated with jaundice have occurred when rifampin is given with **other hepatotoxic agents** (e.g., alcohol, isoniazid). Discontinue one or both drugs for signs of hepatocellular damage. ■ Concurrent use of rifampin with **saquinavir/ritonavir** (ritonavir-boosted saquinavir) is ***contraindicated;*** significant hepatocellular toxicity with markedly increased transaminase elevations has been reported. ■ Concurrent use with praziquantel is ***contraindicated***; see Contraindications. ■ Concurrent administration with **atazanavir, darunavir, fosamprenavir, saquinavir,** and **tipranavir** is ***contraindicated;*** rifampin may substantially decrease plasma concentrations of these antiviral agents. Loss of antiviral effectiveness and/or development of viral resistance may result. ■ Rifampin increases metabolism and clearance and decreases serum levels and effectiveness of numerous drugs. Manufacturer lists **antiarrhythmics, anticonvulsants, antiestrogens, antifungals, benzodiazepine-related drugs, beta-blockers, calcium channel blockers, chloramphenicol, clarithromycin, corticosteroids, cyclosporine, dapsone, diazepam, digoxin, doxycycline, efavirenz, fluoroquinolones, haloperidol, hepatitis C antivirals, indinavir, irinotecan, levothyroxine, methadone, narcotic analgesics, oral anticoagulants, oral hypoglycemic agents, oral or other systemic hormonal contraceptives, progestins, quinine, simvastatin, tacrolimus, theophylline, tricyclic antidepressants, zidovudine**. Other sources add **amiodarone, benzodiazepines, buspirone, estrogens, lamotrigine, losartan,** and **ondansetron**. Increased doses of these drugs may be required. Monitor carefully. ■ Increases requirements of **warfarin**; monitor PT/INR to establish and maintain required anticoagulant dose. ■ Increases metabolism and decreases effectiveness of **oral or other systemic hormonal contraceptives**; use of effective nonhormonal contraception recommended. **Diabetes** may be more difficult to control. ■ May reduce analgesic effects of **morphine and methadone.** Monitor carefully; an alternate analgesic may be required (see earlier statement). ■ Concurrent use of **ketoconazole and rifampin** has resulted in decreased serum concentrations of both drugs. Treatment failure may occur when given concomitantly. ■ Concomitant use of rifampin and **macrolide antibiotics** may decrease the metabolism of rifampin and increase the metabolism of the macrolide antibiotic. ■ **Probenecid and co-trimoxazole** increase blood levels of rifampin. ■ May decrease concentrations of enalaprilat, the active metabolite of **enalapril**, resulting in hypertension. Adjust dose as required. ■ When taken concomitantly, decreased concentrations of **atovaquone** and increased concentration of rifampin have been observed. ■ May induce metabolism of endogenous substrates including **adrenal hormones, thyroid hormones, and vitamin D.** Reduced levels of vitamin D may be accompanied by decreased serum calcium and phosphate and increased parathyroid hormone. ■ Avoid concomitant administration with **cefazolin** in patients at increased risk of bleeding. ■ Cross-reactivity and false-positive urine screening **tests for opiates** have been reported when using certain assays. Gas chromatography or mass spectrometry will distinguish rifampin from opiates. ■ Therapeutic levels inhibit microbiologic assays of **serum folate and vitamin** $\mathbf{B_{12}}$.

SIDE EFFECTS

Abnormal liver function tests, acute generalized exanthematous pustulosis, adrenal insufficiency, agranulocytosis, anorexia, ataxia, behavioral changes, bleeding, cholestasis, conjunctivitis (exudative), cramps, cutaneous reactions (e.g., flushing and itching with or without a rash), decreased hemoglobin, diarrhea, DIC, dizziness, drowsiness, edema of face and extremities, elevated BUN and serum uric acid, epigastric distress, eosinophilia, fatigue, flu-like symptoms (e.g., chills, fever, headache, malaise, muscle and bone pain), gamma-glutamyl transferase, gas, heartburn, hematuria, hemolytic anemia, hepatitis or a shocklike syndrome and abnormal liver function tests, hepatoxicity, hypersensitivity reactions (which may include anaphylaxis, conjunctivitis, DRESS syndrome, eosinophilia, erythema multiforme, pemphigoid reaction, pruritus, rash, sore mouth, sore tongue, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria, vasculitis), hypotension, inability to concentrate, jaundice, leukopenia, menstrual disturbances, mental confusion, muscle weakness, myopathy (rare), nausea, numbness (generalized), pain in extremities, pseudomembranous colitis, psychosis, purpura, renal failure (acute), shortness of breath, thrombocytopenia, tooth discoloration (which may be permanent), visual disturbances, vitamin K–dependent coagulation disorders (abnormal prolongation of prothrombin time or low vitamin K–dependent coagulation factors), vomiting, wheezing.

Overdose:

Abdominal pain; bilirubin levels and/or liver enzymes may increase rapidly; brown-red discoloration of feces, saliva, skin, sweat, tears, and urine is proportional to amount of overdose; headache, lethargy, nausea, and vomiting are immediate; pruritus; unconsciousness. Liver enlargement, possibly with tenderness, can develop within a few hours after severe overdose; bilirubin levels may increase and jaundice may develop rapidly. Arrhythmias, cardiac arrest, hypotension, and seizures have been reported in fatal overdoses.

ANTIDOTE

With increasing severity of any side effect, alterations in liver function tests, flu-like symptoms, purpura, thrombocytopenia, or symptoms of overdose, discontinue the drug and notify the physician immediately. Antiemetics (e.g., ondansetron, prochlorperazine) may be required to control nausea and vomiting. Forced diuresis will promote excretion. Hemodialysis may be indicated. If hemodialysis is not available, peritoneal dialysis can be used along with forced diuresis. In severe overdose or acute toxicity, maintain an adequate airway and confirm adequate respiratory exchange. Treat anaphylaxis and resuscitate as necessary.

RITUXIMAB BBW ■ RITUXIMAB-abbs[a] BBW ■ RITUXIMAB-pvvr[a] BBW ■ RITUXIMAB-arrx[a] BBW

(rih-**TUK**-sih-mab)

Rituxan ■ Truxim[a] ■Ruxience[a] ■ Riabni[a]
Recombinant monoclonal antibody
Antineoplastic (anti-CD20)
Antirheumatic
pH 6.5

USUAL DOSE

Rituximab-abbs (Truxima)[a], rituximab-pvvr (Ruxience)[a], and rituximab-arrx (Riabni)[a] are biosimilar drugs of Rituxan (rituximab). Unless specifically stated otherwise, the information in the monograph applies to all formulations.

Pretreatment:

Verify pregnancy status. Pretesting required and baseline studies indicated; see Precautions and Monitor.

Premedication:

Use recommended for all indications.

Acetaminophen and diphenhydramine are recommended before each dose to prevent or attenuate severe hypersensitivity and/or infusion reactions.

Rituximab (Rituxan and Truxima):

Additional premedication (e.g., methylprednisolone 100 mg IV or equivalent) 30 minutes before each infusion is required for patients with rheumatoid arthritis (RA) and (for **Rituxan**) pemphigus vulgaris (PV).

Rituximab products:

Patients with granulomatosis with polyangiitis (GPA [Wegener's granulomatosis (WG)]) and microscopic polyangiitis (MPA) require additional premedication with methylprednisolone IV 1,000 mg. Patients receiving the 90-minute infusion should receive the glucocorticoid component of their chemotherapy regimen before the rituximab infusion. PCP prophylaxis and/or antiherpetic viral prophylaxis required in specific indications; see Precautions. When administered for oncology-related indications, hydration and antihyperuricemic therapy are recommended for patients at risk for tumor lysis syndrome.

Rituximab Products

Relapsed or refractory, low-grade or follicular, CD20-positive, B-cell non-Hodgkin lymphoma (NHL): Single agent:

Initial therapy: 375 mg/M^2 as an infusion once a week for 4 or 8 doses. See Drug/Lab Interactions. ***Retreatment therapy:*** Patients who subsequently develop progressive disease may be retreated with 375 mg/M^2 as an IV infusion once each week for 4 doses.

Previously untreated follicular, CD20-positive, B-cell NHL:

375 mg/M^2 as an infusion, given on Day 1 of each cycle of chemotherapy for up to 8 doses. In patients with complete or partial response, initiate rituximab maintenance 8 weeks after completion of rituximab in combination with chemotherapy. Administer rituximab as a single agent every 8 weeks for 12 doses.

Nonprogressing, low-grade, CD20-positive, B-cell NHL (after first-line CVP chemotherapy):

In patients who have not progressed following 6 to 8 cycles of CVP chemotherapy (stable disease), 375 mg/M^2 may be administered as an infusion once a week for 4 doses every 6 months for up to 16 doses.

Diffuse large B-cell, CD20-positive NHL:

375 mg/M^2 as an infusion on Day 1 of each cycle of chemotherapy for up to 8 doses.

Chronic lymphocytic leukemia (CLL):

375 mg/M^2 the day before the initiation of FC chemotherapy (fludarabine [Fludara] and cyclophosphamide [Cytoxan]) in the first cycle, then 500 mg/M^2 on Day 1 of Cycles 2 through 6 (every 28 days); see Precautions.

Granulomatosis with polyangiitis (GPA [Wegener's granulomatosis (WG)]) and microscopic polyangiitis (MPA):

Induction treatment of patients with active GPA/MPA: Methylprednisolone:

1,000 mg/day IV for 1 to 3 days followed by oral prednisone 1 mg/kg/day (not to exceed 80 mg/day and tapered per clinical practice) is recommended to treat severe vasculitis symptoms. This regimen should begin within 14 days before or with the initiation of rituximab and may continue during and after the 4-week course of treatment.

Rituximab:

375 mg/M^2 as an infusion once weekly for 4 weeks.

Follow-up treatment (for patients with GPA/MPA who have achieved disease control with induction treatment): Methylprednisolone:

100 mg IV. Complete 30 minutes before each rituximab infusion. ***Rituximab:*** Two 500-mg infusions separated by 2 weeks, followed by a 500-mg infusion every 6 months thereafter based on clinical evaluation. If induction treatment of active disease was with rituximab, follow-up treatment should be initiated within 24 weeks after the last rituximab induction infusion or based on clinical evaluation, but no sooner than 16 weeks after the last induction dose. If induction treatment was with other standard immunosuppressants, rituximab follow-up treatment should be initiated within the 4-week period after achievement of disease control.

Therapeutic regimen with ibritumomab tiuxetan for treatment of NHL:

Rituximab:

250 mg/M^2 as an IV infusion. Given in a specific protocol in combination with the radiotherapeutic antibody ibritumomab tiuxetan (Zevalin); see ibritumomab prescribing information.

Rituxan and Truxima

Rheumatoid arthritis:

Administer ***glucocorticoids*** (e.g., methylprednisolone [Solu-Medrol] 100 mg IV or equivalent) 30 minutes before each infusion of rituximab to reduce the incidence and severity of infusion reactions. Follow with a rituximab infusion of 1,000 mg. Repeat entire sequence one time in 2 weeks. Given in combination with methotrexate. Subsequent courses should be administered every 24 weeks or based on clinical evaluation, but not sooner than every 16 weeks.

Rituxan

Component of the therapeutic regimen with ibritumomab tiuxetan (Zevalin) for treatment of NHL:

Rituximab: 250 mg/M^2 as an IV infusion. Given in a specific protocol in combination with the radiotherapeutic antibody ibritumomab tiuxetan; see ibritumomab prescribing information.

Pemphigus vulgaris:

Additional premedication (e.g., methylprednisolone 100 mg IV or equivalent) 30 minutes before each infusion is required. Administer rituximab as two 1,000-mg infusions separated by 2 weeks in combination with a tapering course of glucocorticoids. ***Maintenance treatment:*** 500 mg as an infusion at month 12 and every 6 months thereafter based on clinical evaluation. ***Treatment of relapse:*** 1,000 mg as an infusion. In addition, consider resuming or increasing the glucocorticoid dose based on clinical evaluation. Subsequent rituximab infusions may be administered no sooner than 16 weeks after the previous infusion.

PEDIATRIC DOSE

Rituxan

Induction treatment of pediatric patients with active GPA/MPA:

Administer Rituxan 375 mg/M^2 as an intravenous infusion once weekly for 4 weeks. Before the first Rituxan infusion, administer IV methylprednisolone 30 mg/kg (not to exceed 1 Gm/day) daily for 3 days. Continue with oral steroids per clinical practice.

Follow-up treatment (for pediatric patients with GPA/MPA who have achieved disease control with induction treatment):

Administer Rituxan as two 250 mg/M^2 IV infusions separated by 2 weeks, followed by 250 mg/M^2 IV infusion every 6 months thereafter based on clinical evaluation. If induction treatment of active disease was with a rituximab product, initiate follow-up treatment with Rituxan within 24 weeks after the last induction infusion with a rituximab product or based on clinical evaluation but no sooner than 16 weeks after the last induction infusion with a rituximab product. If induction treatment of active disease was with other standard of care immunosuppressants, initiate Rituxan follow-up treatment with the 4-week period after achievement of disease control.

DOSE ADJUSTMENTS

No dose adjustments recommended. Has not been formally studied in patients with renal or hepatic impairment. See Rate of Administration. ■ Interrupt or slow infusion rate for infusion-related reactions. Continue the infusion at one-half the previous rate when symptoms subside.

DILUTION

Available in 100 mg/10 mL and 500 mg/50 mL (10 mg/mL) single-dose vials. Each single dose must be further diluted to a final concentration of 1 to 4 mg/mL with NS or D5W. 500 mg (50 mL) in 450 mL will yield 1 mg/mL; 500 mg (50 mL) in 75 mL will yield 4 mg/mL. Gently invert to mix solution. Contains no preservatives; discard any unused portion left in vial.

Storage:

Refrigerate vials at 2° to 8° C (36° to 46° F); protect from light and freezing. Do not shake. Do not use beyond expiration date. Diluted solutions may be refrigerated for 24 hours and are stable at room temperature for an additional 24 hours (refrigeration preferred to RT).

COMPATIBILITY

Manufacturer states, “Rituximab should not be mixed or diluted with other drugs.” No **incompatibilities** with polyvinylchloride or polyethylene bags have been observed.

RATE OF ADMINISTRATION

Must be given as an infusion. ***Do not administer as an IV push or bolus.*** Infusion reactions are a common occurrence and may be prevented or lessened with premedication and a reduced rate of infusion.

First infusion:

Begin with an initial rate of 50 mg/hr (at this rate a 500-mg dose would be infused over 10 hours). If no discomfort or adverse effects occur, may be gradually increased by 50-mg/hr increments at 30-minute intervals to a maximum rate of 400 mg/hr. At any time that discomfort or adverse effects occur, interrupt or reduce the rate of infusion. When symptoms have completely resolved, the infusion can be restarted at half the previous rate. Discontinue the infusion for severe reactions and treat as indicated; see Antidote.

Subsequent infusions:

If the patient did not tolerate the first infusion well, follow instructions under first infusion. If no discomfort or adverse effects occurred with the first infusion, use the following guidelines:

Standard infusion:

Subsequent infusions may begin with an initial rate of 100 mg/hr and increased by 100-mg/hr increments at 30-minute intervals to a maximum rate of 400 mg/hr. See all precautionary measures under First Infusion (see above).

Previously untreated follicular NHL and diffuse large B-cell lymphoma (DLBCL) patients:

If a Grade 3 or 4 infusion-related reaction did not occur during the first infusion, a subsequent 90-minute infusion can be administered with a glucocorticoid-containing chemotherapy regimen. Administer the corticosteroid, acetaminophen, and diphenhydramine; follow with rituximab. Administer 20% of rituximab dose equally distributed over the first 30 minutes and the remaining 80% of the dose equally distributed over 60 minutes. If this initial subsequent 90-minute infusion is tolerated, it can be repeated in the remaining infusions of the protocol. ■ Patients who have clinically significant cardiovascular disease or who have a circulating lymphocyte count equal to or greater than 5,000/mm^3 before Cycle 2 should not be administered the 90-minute infusion.

ACTIONS

An antineoplastic agent. A humanized (Ig)G$_1$ monoclonal antibody produced by recombinant DNA technology. A CD20-directed cytolytic antibody designed to bind to the CD20 antigen found on the surface of normal (pre-B-lymphocytes and mature B-lymphocytes) and malignant B-lymphocytes. Upon binding to CD20, rituximab mediates B-cell lysis. Results in a rapid and sustained depletion of circulating and tissue-based B-cells. Cell lysis may be the result of complement-dependent cytotoxicity and antibody-dependent, cell-mediated toxicity. In oncology patients, rituximab may sensitize drug-resistant human B-cell lymphoma cell lines to cytotoxic chemotherapy.

Detected in serum for 3 to 6 months after completion of therapy. B-cell depletion was sustained for 6 to 9 months posttreatment in 83% of patients. B-cell recovery begins at approximately 6 months, and most levels return to normal by 12 months following completion of treatment. B-cells are believed to play a role in the pathogenesis of rheumatoid arthritis (RA) and associated chronic synovitis. In this setting, B-cells may act at multiple sites in the autoimmune/inflammatory process, including through production of rheumatoid factor and other autoantibodies, antigen presentation, T-cell activation, and/or proinflammatory cytokine production. In RA it induces depletion of peripheral B-lymphocytes, with near-complete depletion occurring in most patients within 2 weeks of the first dose. This B-lymphocyte depletion lasted for at least 6 months, followed by a gradual recovery. Treatment with rituximab in patients with RA was associated with a reduction of certain biologic markers for inflammation. A few patients had prolonged peripheral B-cell depletion lasting more than 3 years after a single course of treatment. Median half-life ranged from 18 to 32 days depending on diagnosis. Crosses the placental barrier. May be secreted in breast milk.

INDICATIONS AND USES

Rituximab Products:

As a single agent in the treatment of patients with relapsed or refractory low-grade or follicular CD20-positive, B-cell NHL. ■ In combination with CHOP (cyclophosphamide, doxorubicin, vincristine, and prednisone) or other anthracycline-based chemotherapy regimens for treatment in previously untreated diffuse large B-cell, CD20-positive NHL. ■ Treatment of previously untreated follicular, CD20-positive, B-cell NHL in combination with first-line chemotherapy and as a single-agent maintenance therapy in patients achieving a complete or partial response to rituximab in combination with chemotherapy. ■ Treatment of nonprogressing (including stable disease), low-grade, CD20-positive, B-cell NHL as a single agent after first-line cyclophosphamide, vincristine, and prednisone (CVP) chemotherapy. ■ Treatment of patients with previously untreated and previously treated CD20-positive CLL. Used in combination with FC chemotherapy (fludarabine and cyclophosphamide). ■ In combination with glucocorticoids for the treatment of adult patients with granulomatosis with polyangiitis (GPA [Wegener's granulomatosis (WG)]) and microscopic polyangiitis (MPA). ■ In combination with ibritumomab tiuxetan as part of a therapeutic regimen for the treatment of patients with relapsed or refractory low-grade or follicular B-cell NHL or for the treatment of previously untreated follicular NHL in patients who have achieved a partial or complete response to first-line chemotherapy. ***Rituxan and Truxima:*** In combination with methotrexate to reduce S/S and to slow the progression of structural damage in adult patients with moderate to severe RA who have had an inadequate response to one or more TNF (tumor necrosis factor) antagonist therapies. ***Rituxan:*** Treatment of patients with moderate to severe pemphigus vulgaris. ***Rituxan:*** In combination with glucocorticoids for the treatment of pediatric patients 2 years of age and older with granulomatosis with polyangiitis (GPA [Wegener's granulomatosis (WG)]) and microscopic polyangiitis (MPA).

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For IV infusion only. Do not administer as an IV push or bolus. ■ Has been given on an outpatient basis; however, rituximab should be administered by or under the direction of the physician specialist in facilities equipped to monitor the patient and respond to any medical emergency. ■ Severe infusion-related reactions have occurred with rituximab infusions, and some have been fatal. Most severe reactions occur within 30 minutes to 2 hours of beginning the first infusion. Deaths within 24 hours of rituximab infusion have occurred. S/S of severe reactions may include hypotension, angioedema, hypoxia, urticaria, or bronchospasm. More severe manifestations may include anaphylactic and anaphylactoid events, pulmonary infiltrates, acute respiratory distress syndrome, myocardial infarction, ventricular fibrillation, and cardiogenic shock. ■ Tumor lysis syndrome (TLS) has been reported within 12 to 24 hours after the first rituximab infusion in patients with NHL. S/S include renal insufficiency, hyperkalemia, hypocalcemia, hyperuricemia, or hyperphosphatemia. May cause acute renal failure requiring dialysis and has been fatal. ■ TLS occurs more often in patients with high numbers of circulating malignant cells or high tumor burden. Consider prophylactic measures; see Monitor. ■ Renal toxicity occurs more frequently in patients with high numbers of circulating malignant cells, high tumor burden, and/or TLS. Severe, including fatal, renal toxicity has occurred in patients with NHL. ■ Safety of immunization with vaccines, particularly live virus vaccines, following rituximab therapy has not been studied. Review vaccination status. Administration of live virus vaccines is not recommended. Weigh benefit versus risk in NHL patients if a delay in treatment may occur for vaccination. ■ Administer any CDC-recommended, non–live virus vaccinations to patients treated with rituximab at least 4 weeks before initiating treatment with rituximab. ■ In CLL patients, *Pneumocystis jiroveci* pneumonia (PCP) and antiherpetic viral prophylaxis is recommended during treatment and for up to 12 months following treatment. ■ In GPA (WG) and MPA patients, *Pneumocystis jiroveci* pneumonia (PCP) prophylaxis is recommended during treatment and for at least 6 months following the last rituximab infusion. ■ In PV patients, *Pneumocystis jiroveci* pneumonia (PCP) prophylaxis is recommended during and after rituximab treatment. ■ Mucocutaneous reactions (including lichenoid dermatitis, paraneoplastic pemphigus, Stevens-Johnson syndrome, toxic epidermal necrolysis, and vesiculobullous dermatitis), some with fatal outcomes, have been reported. Onset of reaction has been variable and includes reports of onset on the first day of rituximab exposure. ■ Hepatitis B virus reactivation with fulminant hepatitis, hepatic failure, and death has been reported. For patients who show evidence of prior hepatitis B infection, consult physician with expertise in managing hepatitis regarding monitoring and consideration for HBV antiviral therapy; see Monitor. ■ Not recommended for use in patients with severe active infections. ■ Serious (including fatal) bacterial, fungal, and new or reactivated viral infections can occur during and following rituximab therapy. Infections have been reported in some patients with prolonged hypogammaglobulinemia (defined as hypogammaglobulinemia more than 11 months after rituximab exposure). New or reactivated viral infections have included JC virus (progressive multifocal leukoencephalopathy [PML], cytomegalovirus, herpes simplex virus, parvovirus B19, varicella zoster virus, West Nile virus, and hepatitis B and C). Deaths have occurred. ■ JC virus infection resulting in PML and death can occur in rituximab-treated patients who have hematologic malignancies or autoimmune diseases. PML is a rare, progressive, demyelinating disease of the CNS. Usually leads to death or severe disability, and there is no effective treatment. Most patients with hematologic malignancies diagnosed with PML received rituximab in combination with chemotherapy or as part of a hematopoietic stem cell transplant. Patients with autoimmune diseases had prior or concurrent immunosuppressive therapy. Most cases of PML were diagnosed within 12 months of the last rituximab infusion. ■ Cardiac adverse reactions, including ventricular fibrillation, myocardial infarction, and cardiogenic shock, have occurred. RA patients may have an increased risk of cardiovascular events. ■ Not indicated for use in patients with RA who have responded to treatment with TNF antagonists (e.g., adalimumab [Humira], etanercept [Enbrel]). ■ Abdominal pain, bowel obstruction, and perforation have been reported in patients receiving rituximab in combination with chemotherapy. Death has occurred. Mean time to GI perforation was 6 days (range 1 to 77 days) in patients with NHL. ■ Use of concomitant immunosuppressants other than corticosteroids has not been studied in GPA (WG), MPA, or PV patients exhibiting peripheral B-cell depletion after treatment with rituximab. ■ As with all therapeutic proteins, there is a potential for immunogenicity. ■ See Rate of Administration, Drug/Lab Interactions, and Antidote.

Monitor:

In patients with lymphoid malignancies who are receiving rituximab monotherapy, obtain a baseline CBC and platelet count and repeat before each course of therapy. In patients treated with rituximab and chemotherapy, obtain baseline CBC and platelet count at weekly to monthly intervals. Repeat more frequently in patients who develop cytopenias (e.g., leukopenia, neutropenia, thrombocytopenia). In RA, GPA (WG), or MPA patients, obtain a baseline CBC and platelet count and repeat at 2- to 4-month intervals during therapy. Duration of cytopenias may extend months beyond the treatment period. ■ Screen all patients for HBV infection before treatment initiation. Monitor patients with evidence of current or prior HBV for clinical and laboratory signs of hepatitis or HBV reactivation during and for several months after treatment with rituximab. HBV reactivation has been reported up to 24 months after completion of rituximab therapy. ■ Observe patient continuously for symptoms of infusion reactions, which are more common during the first infusion but can occur at any time; see Antidote. ■ Monitor HR and BP frequently. ■ ECG and pulmonary monitoring required during and in the immediate posttreatment period in patients with pre-existing cardiac or pulmonary conditions, in any patient who develops or has previously developed a clinically significant cardiopulmonary adverse event during treatment, and in patients with RA. ■ Monitor patients with high numbers of circulating malignant cells (greater than or equal to 25,000/mm^3) with or without other evidence of high tumor burden for infusion reaction and tumor lysis syndrome. Monitoring of serum electrolytes, uric acid, and renal function indicated. ■ Prevention and treatment of hyperuricemia due to TLS may be accomplished with adequate hydration and, if necessary, anti-hyperuricemia agents (e.g., allopurinol [Aloprim]); see Drug/Lab Interactions. ■ Prevention and/or treatment of hyperphosphatemia, hyperkalemia, and hypocalcemia due to TLS is also indicated. ■ Monitor closely for signs of renal failure, and discontinue rituximab in patients with a rising SCr or oliguria. ■ Assess neurologic status frequently. Consider PML in patients with new-onset neurologic manifestations; consultation with a neurologist, brain MRI, and lumbar puncture may be required for diagnosis. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for signs of mucocutaneous reactions. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor patients closely for abdominal pain and repeated vomiting, especially early in the course of treatment. A thorough diagnostic evaluation is indicated; treat appropriately to prevent bowel obstruction and perforation. ■ See Premedication in Usual Dose, Rate of Administration, Precautions, Drug/Lab Interactions, and Antidote.

Patient Education:

Avoid pregnancy. Effective contraception recommended for females of reproductive potential during and for 12 months after rituximab therapy. See Maternal/Child. ■ Read manufacturer's patient information sheet before each infusion. ■ Discuss health history (e.g., presence of an infection, carrier of or had a previous hepatitis B virus infection, heart or lung problems, recent or scheduled vaccinations, scheduled surgeries) and prescription and nonprescription medications with the health care provider administering the rituximab. ■ Review monitoring requirements and potential side effects before therapy. ■ Promptly report any adverse reactions, including S/S of infection (e.g., cold or flu symptoms, dysuria, fever), infusion reactions (e.g., angioedema, breathing problems, chest pain, cough, dizziness, hypotension, palpitations, urticaria), severe mucocutaneous reactions (e.g., blisters, chest pain, painful sores or ulcers on the mouth, peeling skin, rash, and pustules), hepatitis (e.g., abdominal pain, yellow discoloration of the skin or eyes, worsening fatigue), tumor lysis syndrome (e.g., diarrhea, lethargy, nausea, vomiting), cardiovascular complications (e.g., chest pain, irregular heartbeats), or bowel obstruction/perforation (e.g., severe abdominal pain, repeated vomiting); immediate medical treatment may be indicated. ■ New neurologic S/S (e.g., changes in vision, loss of balance or coordination, disorientation, or confusion) could be warning signs of PML. Report them promptly. ■ Laboratory monitoring (e.g., CBC, renal function) required. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy; effective contraception required; see Patient Education. Based on human data, can cause fetal harm due to B-cell lymphocytopenia in infants exposed to rituximab in utero. B-cell lymphocytopenia generally lasting less than 6 months has occurred in infants exposed to rituximab in utero. Use only if clearly needed. Monitor newborns and infants for signs of infection and manage accordingly. ■ Do not breast-feed during treatment and for at least 6 months after the last dose of rituximab. ■ The safety and effectiveness of **rituximab products** have not been established in pediatric patients; however, the safety and effectiveness for use of **Rituxan** in pediatric patients 2 years of age and older has been established for the treatment of GPA and MPA. Hypogammaglobulinemia has been observed in pediatric patients treated with rituximab.

Elderly:

No overall differences in effectiveness were observed between different age-groups of patients treated for diffuse large B-cell NHL. Cardiac and pulmonary adverse reactions (e.g., supraventricular arrhythmia, pneumonia, pneumonitis) occurred more frequently in the elderly. ■ The numbers of elderly treated for low-grade or follicular NHL were insufficient to determine differences in response to therapy, but differences in safety or effectiveness were not identified. ■ The incidence of Grade 3 and 4 adverse reactions was higher in patients over 70 years of age treated for CLL with R-FC. No observed benefit was seen with the addition of rituximab to FC in patients over 65 to 70 years of age. ■ In older patients being treated for RA, GPA, or MPA, the incidence of side effects was similar to younger adults; however, the rate of serious side effects, including serious infection, malignancies, and cardiovascular events, was higher. ■ The numbers of elderly patients treated for PV were insufficient to determine differences in response to therapy.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. ■ Rituximab may lessen the therapeutic effect of **inactivated vaccines** and may enhance the adverse/toxic effects of **live vaccines**; see Precautions. ■ Risk of renal toxicity increased in patients receiving concomitant therapy with **cisplatin** (the combination of cisplatin and rituximab is not an approved treatment regimen). ■ Data on the safety of the use of biologic agents or **disease-modifying antirheumatic drugs** (DMARDs) other than methotrexate in RA patients are limited. Monitor patients closely for signs of infection with concurrent use of biologic agents or DMARDs other than methotrexate. ■ In patients with CLL, rituximab did not alter the systemic exposure to fludarabine or cyclophosphamide. ■ In patients with RA, concomitant administration of methotrexate or cyclophosphamide did not alter the pharmacokinetics of rituximab.

SIDE EFFECTS

Lymphoid malignancies:

CD20-positive, B-cell NHL:

The most common side effects are asthenia, chills, fever, infection, infusion-related reactions, and lymphopenia.

CLL:

The most common side effects during clinical trials were infusion reactions and neutropenia.

Other reported reactions for NHL and CLL included abdominal pain, angioedema, anxiety, arthralgia, back pain, bronchospasm, chest tightness, cough, cytopenias (anemia, leukopenia, lymphopenia, neutropenia, thrombocytopenia), diarrhea, dizziness, dyspnea, flushing, headache, hepato-biliary toxicity, hyperglycemia, hypertension, hypotension, increased LDH, myalgia, nausea, night sweats, pain, peripheral edema, peripheral sensory neuropathy, pruritus, pulmonary toxicity, rash, rhinitis, rigors, sinusitis, throat irritation, urticaria, vomiting, weight gain.

Rheumatoid arthritis:

Common side effects include infusion reactions, cardiac events, and infections (e.g., bronchitis, nasopharyngitis, sinusitis, URI, UTI). Other reported side effects include abdominal pain (upper), anxiety, arthralgia, asthenia, chills, dyspepsia, fever, hypercholesterolemia hypertension, migraine headache, nausea, paresthesia, pruritus, rhinitis, throat irritation, urticaria.

GPA (WG) and MPA:

The most common side effects reported include anemia, diarrhea, headache, infections, infusion reactions, muscle spasm, nausea, and peripheral edema. Other commonly reported side effects include arthralgia, cough, dyspnea, epistaxis, fatigue, hypertension, hypogammaglobulinemia, increased ALT, insomnia, leukopenia, and rash. All major side effects associated with rituximab (e.g., infusion reactions, infections) may occur.

PV:

The most common side effects reported include depression, infections, and infusion reactions. Other reported adverse reactions include abdominal pain (upper), alopecia, conjunctivitis, dizziness, fatigue, fever, headache, herpes simplex, herpes zoster, irritability, musculoskeletal pain, pruritus, skin disorders, tachycardia, and urticaria.

Serious but less frequently reported adverse reactions associated with rituximab therapy include angina, bowel obstruction and perforation, cardiac arrhythmias (e.g., supraventricular and ventricular tachycardia, ventricular fibrillation), hepatitis B reactivation with fulminant hepatitis and other viral infections (including JC virus infection resulting in PML), infusion reactions, mucocutaneous reactions (e.g., lichenoid dermatitis, paraneoplastic pemphigus, Stevens-Johnson syndrome, toxic epidermal necrolysis, and vesiculobullous dermatitis), renal failure, and tumor lysis syndrome (may occur within 12 to 24 hours). Infusion-related side reactions generally occur within 30 minutes to 2 hours of beginning of first infusion and may include any of the following S/S: angioedema, bronchospasm, chills/rigors, dizziness, fever, hypertension, hypotension, myalgia, pruritus, rash, urticaria, or vomiting.

Several other adverse reactions have been reported in fewer than 5% of study patients receiving rituximab.

Post-Marketing:

Bowel obstruction and perforation, bronchiolitis obliterans (fatal), cardiac failure (fatal), disease progression of Kaposi's sarcoma, Grade 3 to 4 prolonged or late-onset neutropenia, hyperviscosity syndrome in Waldenström's macroglobulinemia, hypogammaglobulinemia (prolonged), increase in fatal infections in HIV-associated lymphoma and a reported increased incidence of Grade 3 and 4 infections in patients with previously treated lymphoma without known HIV infection, interstitial lung disease (fatal), lupus-like syndrome, marrow hyperplasia, mucocutaneous reactions (severe) including pyoderma gangrenosum (including genital presentation), optic neuritis, pancytopenia (prolonged), pleuritis, polyarticular arthritis, PRES, RPLS, serum sickness, systemic vasculitis, uveitis, vasculitis with rash, and viral infections, including PML.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Infusion-related side effects generally resolve with slowing or interruption of the rituximab infusion and with supportive care (IV saline; diphenhydramine; bronchodilators such as albuterol or aminophylline; and acetaminophen). Most patients who have had non–life-threatening reactions have been able to complete the full course of therapy. Restart the infusion at half the previous rate after symptoms have resolved completely. Discontinue the infusion immediately for any life-threatening side effect (e.g., clinically significant bronchospasm, cardiac arrhythmias, Grade 3 or 4 infusion reactions, hypersensitivity reactions, hypotension, tumor lysis syndrome, or severe mucocutaneous reaction). Discontinue rituximab in any patient who develops a serious infection or experiences HBV reactivation. Initiate appropriate antiviral/anti-infective therapy as indicated. Discontinue treatment in patients who develop severe mucocutaneous reactions. Skin biopsy may be required to diagnose mucocutaneous reaction and guide treatment. Safety of readministration of rituximab to patients with severe mucocutaneous reactions has not been determined. Discontinue treatment in patients who develop PML; consider reduction or discontinuation of concomitant chemotherapy or immunosuppressive therapy. Discontinue treatment in patients with a rising SCr or oliguria. Treat severe infusion reactions/anaphylaxis with oxygen, antihistamines (diphenhydramine), epinephrine, and corticosteroids as indicated. Maintain a patent airway. Discontinue rituximab for serious or life-threatening cardiac arrhythmias and treat as indicated. Treat hypotension with IV fluids, Trendelenburg position, and, if necessary, vasopressors (e.g., norepinephrine, dopamine). Blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Tumor lysis syndrome requires correction of electrolyte abnormalities and monitoring of renal function and fluid balance. Supportive care, including dialysis, may be required. Resuscitate if indicated.

ROCURONIUM BROMIDE

(roh-kyou-**ROH**-nee-um **BRO**-myd)
Zemuron
Neuromuscular blocking agent (nondepolarizing)
pH 4

USUAL DOSE

Must be individualized, depending on previous drugs administered and degree and length of muscle relaxation required. Should be used with adequate anesthesia and after unconsciousness has been induced. A peripheral nerve stimulator should be used to monitor drug effect, determine the need for additional doses, confirm the adequacy of recovery from or antagonism of neuromuscular block, and decrease the complications of overdose if additional doses are administered. See Precautions and Drug/Lab Interactions.

Rapid sequence intubation:

0.6 to 1.2 mg/kg of body weight as an initial dose. Patient should be appropriately premedicated and adequately anesthetized. Should provide excellent or good intubating conditions within 2 minutes.

Tracheal intubation: An initial dose

of 0.6 mg/kg regardless of anesthetic technique. Neuromuscular block sufficient for intubation is usually achieved in 1 minute (range 0.4 to 6 minutes); and most patients have intubation completed within 2 minutes. Maximum blockade is achieved within 3 minutes, and dose is expected to provide 15 to 85 minutes (average 31 minutes) of clinical relaxation. **A lower dose** of 0.45 mg/kg may be used. Neuromuscular block sufficient for intubation is usually achieved in 1.3 minutes (range 0.8 to 6.2 minutes), and most patients have intubation completed within 2 minutes. Maximum blockade is achieved within 4 minutes, and dose is expected to provide 12 to 31 minutes (average 22 minutes) of clinical relaxation under opioid/nitrous oxide/oxygen anesthesia. With this lower dose, expect a more rapid time to 25% recovery (12 to 15 minutes). **Larger bolus doses** of 0.9 mg/kg or 1.2 mg/kg under opioid/nitrous oxide/oxygen anesthesia may be used in selected patients without adverse effects to the cardiovascular system.

Maintenance dose:

0.1, 0.15, and 0.2 mg/kg administered at 25% recovery of control T1 (defined as 3 twitches of train-of-four) will extend relaxation another 12 (range 2 to 31), 17 (range 6 to 50), and 24 (range 7 to 69) minutes, respectively, under opioid/nitrous oxide/oxygen anesthesia. Should not be administered until recovery of neuromuscular function is evident. Repetitive dosing may produce a clinically insignificant cumulative effect. Usually given as a bolus, may be given as an infusion; see Rate of Administration.

PEDIATRIC DOSE

Must be individualized depending on previous drugs administered and the degree and length of muscle relaxation required. Should be used with adequate anesthesia and after unconsciousness has been induced. A peripheral nerve stimulator should be used to monitor drug effect, determine the need for additional doses, confirm the adequacy of recovery from or antagonism of neuromuscular block, and decrease the complications of overdose if additional doses are administered. See Precautions and Drug/Lab Interactions.

Rapid sequence intubation:

Not recommended for rapid sequence intubation in pediatric patients.

Tracheal intubation:

Usual **initial dose** is 0.6 mg/kg; however, a **lower dose** of 0.45 mg/kg may be used depending on anesthetic technique and the age of the patient. Depending on the type of induction anesthesia, intubation is usually achieved in 60 to 75 seconds. Time to maximum block is shortest in infants (28 days to 3 months) and longest in neonates (birth to less than 28 days). The duration of clinical relaxation following an intubation dose is shortest in pediatric patients more than 2 years up to 11 years and longest in infants.

Maintenance dose:

0.075 to 0.125 mg/kg when halothane is used as the general anesthetic in pediatric patients from 3 months through adolescence. Administration upon return of T1 to 25% recovery will provide relaxation for 7 to 10 minutes. Alternately, an infusion of 0.012 mg/kg/min (12 mcg/kg/min) may be initiated upon return of T1 to 10% (one twitch present in train-of-four) to maintain neuromuscular blockade. Adjust rate based on twitch response to peripheral nerve stimulation.

0.15 mg/kg at reappearance of T3 (three twitches present in train-of-four) when sevoflurane is used for induction and isoflurane/nitrous oxide is used for maintenance of general anesthesia in all pediatric age-groups. Alternately, at reappearance of T2 (two twitches present in train-of-four), an infusion at a rate of 7 to 10 mcg/kg/min may be administered. Neonates (birth to less than 28 days) have the lowest dose requirement, and pediatric patients more than 2 years up to 11 years have the highest dose requirement.

DOSE ADJUSTMENTS

Initial dose should be based on actual body weight in obese patients. ■ Reduced initial and maintenance doses may be required in presence of some inhalation anesthetics (e.g., isoflurane, enflurane) and with other drugs that prolong neuromuscular blockade (see Drug/Lab Interactions). ■ Reduced dose may be required in impaired hepatic function. ■ When rapid sequence intubation is required in patients with ascites, an increased initial dose may be necessary to ensure complete block. Duration will be prolonged in these cases. ■ Reduced dose indicated in cachectic or debilitated patients and those with neuromuscular diseases (e.g., myasthenia gravis) or carcinomatosis. ■ Patients with burns, cerebral palsy, disuse atrophy, denervation, or direct muscle trauma may be resistant and require increased doses. ■ Consider dose adjustment for patients in whom potentiation of, or resistance to, neuromuscular blockade is anticipated; see Precautions. ■ Patients with prolonged circulation times (e.g., advanced age, cardiovascular disease) may experience a delay in onset of effect. Do not increase initial dose. Instead, if feasible, allow more time for drug to achieve onset of effect. ■ Chronic use of anticonvulsants may require increased doses. ■ Dose adjustment not indicated in patients with reduced plasma cholinesterase activity. ■ See Drug/Lab Interactions.

DILUTION

IV injection:

May be given undiluted.

Infusion:

Compatible in solution with NS, D5W, D5/S, LR, or SW in concentrations up to 5 mg/mL. May be further diluted and administered as an infusion; see Rate of Administration. Diluting 100 mg in 100 mL of solution yields 1 mg/mL. See Rate of Administration.

Storage:

Store with the cap and ferrule intact and in a manner that minimizes the possibility of selecting the wrong product. Refrigerate vials 2° to 8° C (36° to 46° F); do not freeze. Unopened vials stable at room temperature for up to 60 days. Use opened vials within 30 days. Use diluted solutions (concentrations up to 5 mg/mL) within 24 hours. Discard unused solution.

COMPATIBILITY

Manufacturer states, "Should not be mixed with alkaline solutions (e.g., barbiturates, phenytoin, sodium bicarbonate) in the same syringe or administered simultaneously during IV infusion through the same needle." Manufacturer lists as **incompatible** with amphotericin B (conventional), azathioprine, cefazolin, dexamethasone, diazepam, erythromycin, famotidine, fat emulsion IV, furosemide, hydrocortisone sodium succinate, insulin, ketorolac, lorazepam, methohexital, methylprednisolone, sulfamethoxazole/trimethoprim, thiopental, vancomycin.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Peripheral nerve stimulator required; see Usual Dose. Manufacturer's literature contains drug delivery rates for 0.5 mg/mL, 1 mg/mL, and 5 mg/mL concentrations of rocuronium. Flush infusion line adequately before and after administration of rocuronium to avoid unknown **incompatibility** problems.

IV injection:

A single dose over 5 to 15 seconds as the initial or maintenance dose. Titrate to desired effect.

Infusion:

0.01 to 0.012 mg/kg/min (10 to 12 mcg/kg/min) as a maintenance infusion after early evidence of spontaneous recovery from intubating dose (return of T1 to 10% [one twitch present in train-of-four]). Because of rapid redistribution and the associated rapid spontaneous recovery, additional boluses may be required if begun after more than 10% of control T1. Must be individualized. When desired level of neuromuscular block is achieved, adjust the rate of administration according to the patient's twitch response as monitored with the use of a peripheral nerve stimulator. The usual rate is 0.004 to 0.016 mg/kg/min (4 to 16 mcg/kg/min). With steady-state concentrations of enflurane or isoflurane, rate reductions of 30% to 50% may be indicated 45 to 60 minutes after the intubating dose. After discontinuation of the infusion, spontaneous recovery and reversal of neuromuscular blockade may be expected to be similar to that seen with a comparable total of repetitive bolus injections.

Pediatric infusion rate:

See Pediatric Dose and comments under Infusion (above).

ACTIONS

A nondepolarizing neuromuscular blocking agent with a rapid to intermediate onset of action depending on dose. Has intermediate duration of action. Causes skeletal muscle relaxation and paralysis by competing for cholinergic receptors at the motor end-plate. Action is antagonized by acetylcholinesterase inhibitors (e.g., neostigmine). Good intubating conditions are dose dependent and occur in 1 to 2 minutes. Maximum neuromuscular blockade occurs within 4 minutes. Average clinical duration is 31 minutes with the recommended initial dose. Elimination half-life is 1.4 hours. Somewhat bound to plasma protein (30%). Has minimal impact on the cardiovascular system, although cases of tachycardia have been reported. May cause some histamine release, usually not clinically significant. Metabolized in the liver and excreted in bile and urine. Crosses placental barrier.

INDICATIONS AND USES

Adjunct to general anesthesia to facilitate both rapid sequence and routine tracheal intubation, and to provide skeletal muscle relaxation during surgery or mechanical ventilation.

CONTRAINDICATIONS

Known hypersensitivity to rocuronium or other neuromuscular blocking agents. Not recommended for rapid-sequence induction in cesarean section or in pediatric patients.

PRECAUTIONS

For IV use only. ■ Administered only by or under the direct observation of experienced clinicians in a facility with adequate diagnostic and treatment facilities and appropriate emergency drugs and equipment to monitor the patient and respond to any medical emergency. ■ ***Severe anaphylactic reactions have been reported with neuromuscular blocking agents; some have been fatal.*** Use caution in patients who have had an anaphylactic reaction to another neuromuscular blocking agent (depolarizing or nondepolarizing); cross-reactivity has occurred; see Contraindications. ■ Accidental administration due to medication errors can cause death. ■ Results in paralysis, which may lead to respiratory arrest and death. Confirm drug and avoid confusion with other medications that are present. If another health care provider is administering the drug, ensure that the intended dose is clearly labeled and communicated. ■ Patient may be conscious and completely unable to communicate by any means. Must be used with adequate anesthesia or sedation; has no analgesic or sedative properties. ■ Time of onset is similar, but duration of action is variable in impaired renal function and prolonged 1.5 times in impaired hepatic function; use with caution. ■ May cause increased pulmonary vascular resistance; use caution in patients with pulmonary hypertension or valvular heart disease. ■ Use caution and allow time for drug to achieve onset of effects in altered circulation time (e.g., cardiovascular disease, advanced age). ■ Neuromuscular blocking effects are increased in cachectic or debilitated patients and in patients with neuromuscular diseases (e.g., myasthenia gravis) or carcinomatosis. May cause critical reactions in patients with myasthenia gravis or myasthenic (Eaton-Lambert) syndrome; use of a peripheral nerve stimulator and a small test dose should be considered. ■ Use caution in patients with severe acid-base and/or electrolyte abnormalities (e.g., adrenocortical insufficiency, diarrhea, metabolic acidosis, metabolic alkalosis, respiratory alkalosis); neuromuscular blocking effects may be potentiated or inhibited. ■ To prevent complications from residual paralysis, extubation should be delayed until after the patient has sufficiently recovered from neuromuscular block; see Elderly. Use of a reversal agent should be considered for cases in which residual paralysis is more likely to occur. ■ Concomitant use of rocuronium and general anesthetic agents has prolonged the QT interval in pediatric patients. ■ Has not been studied for long-term use in the ICU. Tolerance to rocuronium may develop. Continuous use of a peripheral nerve stimulator is strongly recommended if used in this situation. Additional doses should not be given until there is a definite response to nerve stimulation. Myopathy has been reported with long-term use; may occur with neuromuscular blocking agents used alone or in combination with corticosteroid therapy. See Usual Dose and Dose Adjustments. May cause prolonged paralysis or skeletal muscle weakness during weaning. ■ Flush eyes with water for at least 10 minutes for accidental contact. ■ See Drug/Lab Interactions.

Monitor:

This drug produces apnea. Controlled artificial ventilation with oxygen must be continuous and under direct observation at all times. Maintain a patent airway. Neostigmine or edrophonium and atropine must be available. ■ Monitor all vital organ functions until adequate recovery. ■ Monitor for S/S of hypersensitivity reactions; see Precautions. ■ Use a peripheral nerve stimulator to monitor response to rocuronium, avoid overdose, monitor need for additional relaxant, and monitor adequacy of spontaneous recovery or antagonism. ■ Action may be altered by dehydration, electrolyte imbalance, body temperatures, and acid-base imbalance; monitor closely. ■ Monitor for early signs of malignant hyperthermia; has not occurred but is a possibility. ■ See Drug/Lab Interactions. ■ If extravasation occurs, discontinue infusion and use another vein.

Patient Education:

Discuss medical history, current medications, and any history of hypersensitivity to neuromuscular blocking agents with health care professionals.

Maternal/Child:

Benefits must justify potential risk to fetus. No teratogenic effects noted in rats. ■ See Contraindications. ■ Safety for use during breast-feeding not established. ■ Has been used in pediatric patients up to 17 years of age (including neonates) under sevoflurane (induction) and isoflurane/nitrous oxide (maintenance) anesthesia. Onset time and clinical duration varied with dose, age of patient, and anesthetic technique. Has been used in pediatric patients 3 months to 14 years of age under halothane anesthesia. May cause a transient increase in HR after intubation in pediatric patients who do not receive atropine before induction. ■ Concomitant use with general anesthetic agents can prolong the QTc interval in pediatric patients. ■ Not recommended for rapid sequence intubation in pediatric patients.

Elderly:

Effects not significantly different from younger adults, but greater sensitivity of some older individuals cannot be ruled out. Onset time and duration of action may be slightly longer in elderly patients. Consider slower circulation time in cardiovascular disease, advanced age, edematous states, and impaired liver function. Patients 65 years of age or older may be at increased risk for residual neuromuscular block; see Precautions.

DRUG/LAB INTERACTIONS

Duration of action extended and recovery prolonged by **inhalation anesthetics** (e.g., enflurane, isoflurane); reduced doses required. ■ Patients receiving **chronic anticonvulsants** (e.g., carbamazepine, phenytoin) may be resistant to nondepolarizing muscle relaxants and require higher doses. ■ Prolongation of neuromuscular block may occur with **many antibiotics** (e.g., aminoglycosides [e.g., gentamicin, tobramycin], bacitracin, colistin, colistimethate, polymyxin B, tetracycline, vancomycin), **lithium, local anesthetics, magnesium salts, procainamide, quinidine, and other nondepolarizing muscle relaxants.** Reduced doses of rocuronium may be required. ■ May cause recurrent paralysis with **quinidine.** ■ **Succinylcholine** must show signs of wearing off before rocuronium is given. Use before succinylcholine to reduce side effects has not been studied. ■ Concomitant use with propofol does not alter the clinical duration or recovery characteristics of rocuronium.

SIDE EFFECTS

Occurred in fewer than 1% of patients. Hypertension and hypotension (transient) are most common. Abnormal electrocardiogram (including prolonged QT interval), arrhythmia (e.g., tachycardia), bronchospasm, hiccup, increased pulmonary vascular resistance, injection site edema, myopathy, nausea, pruritus, rash, residual paralysis, rhonchi, vomiting, and wheezing have been reported. Serious adverse reactions include hypersensitivity reactions (including anaphylaxis), increased pulmonary vascular resistance, myopathy, and residual paralysis.

Post-Marketing:

Hypersensitivity reactions, including anaphylaxis and shock resulting in death, have been reported. Malignant hyperthermia has also been reported.

ANTIDOTE

All side effects resulting from overdose or prolonged action can be medical emergencies. Maintenance of a patent airway, controlled ventilation, oxygenation, and adequate sedation required until recovery of normal neuromuscular function. Treat symptomatically and monitor continuously. Do not administer an anticholinesterase agent until there has been demonstration of some spontaneous recovery from neuromuscular blockade (e.g., 5-second head lift, adequate phonation, ventilation, and upper airway patency). Use of a nerve stimulator to document recovery is recommended. Once spontaneous recovery has reached 25% of control T1, the neuromuscular block produced by rocuronium is readily reversed by neostigmine (Bloxiverz [usual dose 0.03 mg/kg]). Administer atropine before or concurrently with neostigmine. Reversal to 75% recovery usually occurs within 15 minutes. Rarely, additional antagonists may be required.

ROMIDEPSIN

(**ROE**-mi-**DEP**-sin)
Istodax
Antineoplastic (histone deacetylase [HDAC] inhibitor)

USUAL DOSE

Pretreatment:

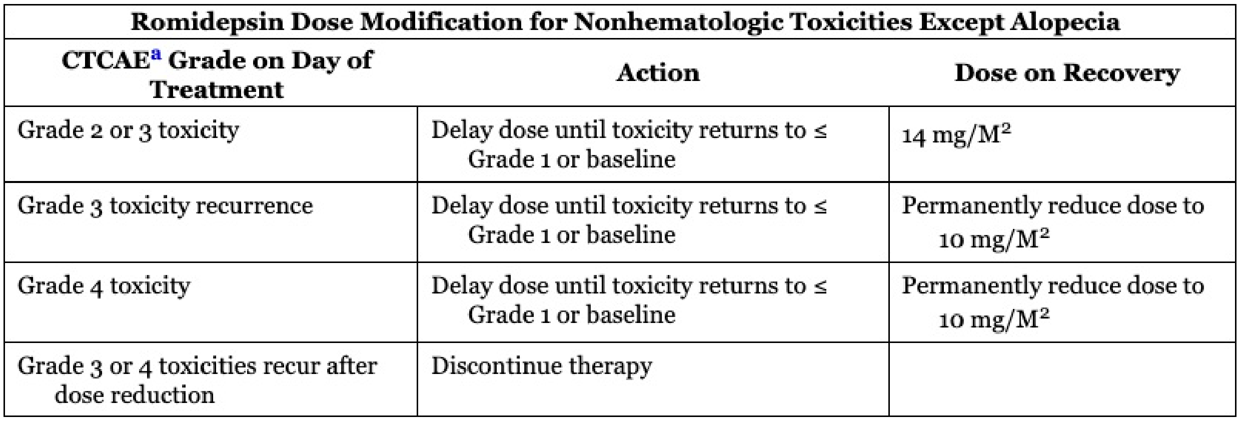
Verify pregnancy status. Baseline studies indicated; see Monitor.

Romidepsin:

14 mg/M^2 as an infusion over 4 hours. Administer on Days 1, 8, and 15 of a 28-day cycle; see Monitor. Cycles may be repeated every 28 days provided the patient continues to benefit from and tolerates the drug.

DOSE ADJUSTMENTS

Discontinuation or interruption with or without dose reduction to 10 mg/M^2 may be needed to manage adverse drug reactions as outlined in the following charts.



Romidepsin Dose Modification for Nonhematologic Toxicities Except Alopecia

CTCAE[a] Grade on Day of Treatment	Action	Dose on Recovery
Grade 2 or 3 toxicity	Delay dose until toxicity returns to ≤ Grade 1 or baseline	14 mg/M^2
Grade 3 toxicity recurrence	Delay dose until toxicity returns to ≤ Grade 1 or baseline	Permanently reduce dose to 10 mg/M^2
Grade 4 toxicity	Delay dose until toxicity returns to ≤ Grade 1 or baseline	Permanently reduce dose to 10 mg/M^2
Grade 3 or 4 toxicities recur after dose reduction	Discontinue therapy	

[a] Per Common Terminology Criteria for Adverse Events (CTCAE), Version 4.0.

Romidepsin Dose Modification for Hematologic Toxicities		
CTCAE[a] Grade on Day of Treatment	Action	Dose on Recovery
Grade 3 or 4 neutropenia or thrombocytopenia	Delay dose until ANC ≥1,500/mm^3 and/or platelet count ≥75,000/mm^3 or baseline	14 mg/M^2
Grade 4 febrile (≥38.5° C) neutropenia or thrombocytopenia that requires platelet transfusion	Delay dose until the specific cytopenia returns to ≤ Grade 1 or baseline	Permanently reduce dose to 10 mg/M^2

[a] Per Common Terminology Criteria for Adverse Events (CTCAE), Version 4.0.

■ No dose adjustments required based on age; gender; race; mild, moderate, or severe renal impairment; or mild hepatic impairment. ■ Adjust starting dose for patients with moderate or severe hepatic impairment as shown in the following chart; see Monitor.

Recommendations for Starting Dose in Patients With Moderate and Severe Hepatic Impairment		
Hepatic Impairment	Bilirubin Levels	Romidepsin Dose
Moderate	>1.5 × ULN to ≤3 × ULN	7 mg/M^2
Severe	>3 × ULN	5 mg/M^2

ULN, Upper limit of normal.

DILUTION

Special techniques required; see Precautions:

Romidepsin and diluent vials contain an overfill to ensure that the recommended volume can be withdrawn at a concentration of 5 mg/mL. Reconstitute each 10-mg single-dose vial with 2.2 mL of the supplied diluent. Inject diluent slowly into the vial of romidepsin and swirl contents until there are no visible particles. Concentration equals 5 mg/mL. Withdraw the calculated dose and further dilute in 500 mL NS.

Filters:

Specific information not available.

Storage:

Store vials in carton at CRT. Reconstituted solution is stable for up to 8 hours at RT. Diluted solutions are stable at RT for 24 hours, but use soon after dilution is recommended.

COMPATIBILITY

Manufacturer states, “The diluted solution is **compatible** with polyvinyl chloride (PVC), ethylene vinyl acetate (EVA), polyethylene (PE) infusion bags as well as glass bottles.” No additional information available; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 4 hours.

ACTIONS

A histone deacetylase (HDAC) inhibitor. HDACs catalyze the removal of acetyl groups from acetylated lysine residues in histones, resulting in the modulation of gene expression. Induces cell cycle arrest and apoptosis of some cancer cell lines. Mechanism of antineoplastic effect not fully characterized. Highly protein bound. It undergoes extensive metabolism in vitro by CYP3A4 with minor contributions from other cytochrome P_{450} isoenzymes. Half-life is approximately 3 hours. No accumulation of plasma concentration observed after repeated dosing.

INDICATIONS AND USES

Treatment of cutaneous T-cell lymphoma (CTCL) in adult patients who have received at least one prior systemic therapy. ■ Treatment of peripheral T-cell lymphoma (PTCL) in adult patients who have received at least one prior therapy. This indication is approved under accelerated approval based on response rate. Continued approval for this indication may be contingent on verification and description of clinical benefit in confirmatory trials.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patients and respond to any medical emergency. ■ Myelosuppression can occur (e.g., anemia, lymphopenia, neutropenia, and thrombocytopenia). Dose modification based on ANC, and platelet count is required; see Dose Adjustments. ■ Serious and sometimes fatal infections, including pneumonia, sepsis, and viral reactivation (including Epstein-Barr and hepatitis B viruses), have been reported during or within 30 days of therapy. Patients with a history of prior treatment with monoclonal antibodies directed against lymphocyte antigens and patients with disease involvement of the bone marrow may be at increased risk for developing a life-threatening infection. ■ Reactivation of Epstein-Barr viral infection leading to liver failure has occurred. In one case, ganciclovir prophylaxis failed to prevent Epstein-Barr viral reactivation. ■ Several treatment-emergent ECG changes have been reported (e.g., T-wave and ST-segment changes, QT prolongation); clinical significance is unknown. Use caution in patients with congenital long QT syndrome or a history of significant CV disease or in patients taking antiarrhythmic or other medicines that can lead to significant QT prolongation; see Drug/Lab Interactions. ■ Tumor lysis syndrome has been reported. Patients with advanced disease and/or high tumor burden are at greater risk. ■ Use with caution in patients with moderate or severe hepatic impairment; see Dose Adjustments and

Monitor. ■ Renal impairment is not expected to influence romidepsin exposure. Effect on end-stage renal disease (ESRD) has not been studied; use with caution in patients with ESRD.

Monitor:

Due to the risk of QT prolongation, potassium and magnesium should be within the normal range before administration of romidepsin. ■ Obtain baseline CBC, platelets, electrolytes, and liver function tests. Baseline CrCl or SCr may be indicated. ■ Monitor CBC, platelets, and electrolytes during treatment and modify dose as indicated; see Dose Adjustments. ■ Consider ECG monitoring and more frequent monitoring of electrolytes in at-risk cardiac patients; see Precautions. ■ Monitor for signs of tumor lysis syndrome. Prevention and treatment of hyperuricemia may be accomplished with adequate hydration and, if necessary, antihyperuricemia agents (e.g., allopurinol). ■ Monitor patients with hepatic impairment more frequently for toxicity, especially during the first cycle. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Use prophylactic antiemetics to reduce nausea and/or vomiting and increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitoring for hepatitis B reactivation and administration of antiviral prophylaxis should be considered in patients with evidence of prior hepatitis B infection.

Patient Education:

Read patient insert carefully. ■ Verify pregnancy status within 7 days of initiating romidepsin therapy. ■ Avoid pregnancy; use of effective contraception is recommended for females of reproductive potential and for males with female partners of reproductive potential during treatment and for at least 1 month after the final dose. Because romidepsin may reduce the effectiveness of estrogen-containing contraceptives, alternative methods with non–estrogen-containing contraceptives (e.g., condoms, intrauterine device) should be used. ■ May cause male and female infertility. ■ Blood counts will be required at regular intervals. ■ Report any history of hepatitis B before starting therapy. ■ Maintain high fluid intake for at least 72 hours after each dose to decrease the risks associated with tumor lysis syndrome. ■ Promptly report unusual bleeding, abnormal heartbeat, chest pain, or shortness of breath. ■ Report burning on urination, cough, fever, flu-like symptoms, muscle aches, or worsening of skin problems. ■ Nausea and vomiting are common. Prophylactic antiemetics are recommended. ■ Discuss medications (prescription, nonprescription, and herbal) with a health care professional; see Drug/Lab Interactions. ■ See Appendix D, p. 1311.

Maternal/Child:

Based on its mechanism of action and findings from animal studies, romidepsin can cause fetal harm when administered to a pregnant woman. ■ Do not breast-feed during treatment and for at least 1 week after the last dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No differences in safety and effectiveness compared with younger patients were noted; however; greater sensitivity of some older patients cannot be ruled out.

DRUG/LAB INTERACTIONS

Concurrent use with **warfarin** may prolong PT and elevate INR. Monitoring of PT and INR recommended. ■ **Strong CYP3A4 inhibitors** (e.g., atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, and voriconazole) may increase concentrations of romidepsin; monitor for toxicity and follow dose modifications for toxicity; see Dose Adjustments. Use caution with concomitant use of **moderate CYP3A4** inhibitors (aprepitant, verapamil). ■ Avoid coadministration with **rifampin (a strong CYP3A4 inducer).** In a pharmacokinetic drug interaction trial, romidepsin exposure was *increased* when coadministered with rifampin. Typically, coadministration of CYP3A4 inducers decreases concentrations of drugs metabolized by CYP3A4. The increase in exposure seen after coadministration with rifampin is likely due to rifampin's inhibition of an undetermined hepatic uptake process that is predominantly responsible for the disposition of romidepsin. It is unknown whether other **potent CYP3A4 inducers** (e.g., carbamazepine, phenobarbital, phenytoin, rifabutin, rifapentine, and St. John's wort) would alter the exposure of romidepsin. Avoid coadministration with other potent CYP3A4 inducers if possible. ■ Use caution with **drugs that inhibit the efflux transporter P-glycoprotein**; may increase concentrations of romidepsin. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Concurrent use with other **drugs that prolong the QT interval** (e.g., antiarrhythmics [e.g., amiodarone, disopyramide, ibutilide, mexiletine, procainamide, quinidine], antihistamines, azole antifungals, fluoroquinolones, phenothiazines, and tricyclic antidepressants) may cause torsades de pointes and could be fatal.

SIDE EFFECTS

The most common side effects are anorexia, ECG T-wave changes, fatigue, infections, myelosuppression (e.g., anemia, lymphopenia, neutropenia, thrombocytopenia), nausea, and vomiting. Anemia, dyspnea, elevated AST, fatigue, hypomagnesemia, infection, pneumonia, QT prolongation, and thrombocytopenia were the most common reasons for discontinuing therapy. Adverse reactions categorized as severe included abdominal pain, acute renal failure, cardiopulmonary failure, cellulitis, central line infection, chest pain, deep venous thrombosis, dehydration, dyspnea, edema, elevated ALT and AST, fatigue, febrile neutropenia, fever, hyperbilirubinemia, hypersensitivity, hyperuricemia, hypoalbuminemia, hypocalcemia, hypophosphatemia, hypotension, hypoxia, infection, leukopenia, lymphopenia, nausea, neutropenia, pneumonitis, pulmonary embolism, reactivation of hepatitis B infection, sepsis, supraventricular arrhythmia, syncope, thrombocytopenia, ventricular arrhythmia, and vomiting. Other side effects reported include asthenia, constipation, dermatitis, diarrhea, dysgeusia, exfoliative dermatitis, hyperglycemia, hypermagnesemia, hypokalemia, hyponatremia, and pruritus.

ANTIDOTE

Treatment of most side effects will be supportive and may require dose delay, dose adjustment, or discontinuation; see Dose Adjustments. Discontinue if Grade 3 or 4 toxicities recur after dose reduction. Keep physician informed. Administration of blood products and/or blood modifiers (e.g., darbepoetin, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Treat hypersensitivity reactions with epinephrine, antihistamines, and corticosteroids as needed. No known antidote. Discontinue romidepsin and provide supportive therapy in overdose. Not known if romidepsin is dialyzable. Resuscitate if indicated.

Trodelvy
Antineoplastic agent
Topoisomerase I inhibitor

USUAL DOSE

10 mg/kg IV on Days 1 and 8 of a 21-day treatment cycle. Continue until unacceptable toxicity or disease progression.

PEDIATRIC DOSE

Safety and efficacy have not been established.

DOSE ADJUSTMENTS

Renal:

No dosage adjustments provided by manufacturer.

Hepatic:

No dosage adjustments provided by manufacturer.

Hematologic:

See manufacturer product information for specifics.

DILUTION

Allow vials to warm to room temperature. Reconstitute each vial with 20 mL of NS to a concentration of 10 mg/mL. Gently swirl vial for dissolution; may take up to 15 minutes; ***do not shake***. Solution should be yellow and clear. After complete dissolution, immediately transfer the prescribed dose to a PVC, polypropylene, or ethylene/propylene copolymer infusion bag slowly to avoid foaming. Adjust volume in the infusion bag with NS as needed to a concentration of 1.1 to 3.4 mg/mL. Total volume per bag should not exceed 500 mL. If dose requires more than one 500-mL bag, divide and infuse sequentially.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than NS.

RATE OF ADMINISTRATION

Administer initial dose as an IV infusion over 3 hours; subsequent doses can be given over 1 to 2 hours if tolerated. Flush infusion line with 20 mL of NS. Do not give as an IV push or bolus. Administer infusion within 4 hours of administration (including infusion time).

ACTIONS

Sacituzumab govitecan is a topoisomerase 1 inhibitor, which leads to DNA damage, apoptosis, and cell death.

INDICATIONS AND USES

Breast cancer, urothelial cancer.

CONTRAINDICATIONS

Severe hypersensitivity to drug or any component of the formulation.

PRECAUTIONS

Bone marrow suppression, GI toxicity, reduced UGT1A1 activity, polysorbate allergy, hypersensitivity.

Monitor:

Blood counts prior to dose on Days 1 and 8 of each cycle and as clinically necessary. Hepatitis B virus screen prior to starting.

Patient Education:

Advise patients to call physician if they experience infection, severe diarrhea, black or blood stools, dehydration or inability to take fluids by mouth, high blood sugar (confusion, increased thirst, hunger, frequent urination, fruity-smelling breath), electrolyte problems (mood changes, confusion, muscle weakness or pain, irregular heartbeat, vomiting), swelling, unexplained bruising or bleeding, numbness, not passing urine.

Maternal/Child:

Check pregnancy status prior to use. Advise patient to use effective contraception during therapy and at least 6 months after last dose. May cause fetal harm. Breast-feeding is not recommended.

Elderly:

Refer to adult dosing and precautions.

DRUG/LAB INTERACTIONS

5-ASA, bacille Calmette-Guérin (BCG) vaccine, baricitnib, brincidofovir, chloramphenicol ophthalmic, cladribine, clozapine, COVID-19 vaccines (may decrease effectiveness), moderate and strong CYP3A4 inducers (may decrease effectiveness of sacituzumab govitecan; avoid), strong CYP3A4 inhibitors (may increase serum concentration of sacituzumab govitecan; avoid), deferiprone, denosumab, dipyrone, Echinacea, fexinidazole, fingolimod, inebilzumab, leflunomide, lenograstim, lipegfilgrastim, MMR vaccine (avoid), natalizumab, ocrelizumab, ofatumumab, ozanimod, pidotimod, pimecrolimus (avoid), ponesimod, promazine, rabies vaccine, roflumilast, spionimod, sipuleucel-T, smallpox and monkey pox vaccine, tacrolimus topical (avoid), talimogene laherparepvec (avoid), tertomotide, tofacitinib, UGT1A1 inducers and inhibitors (avoid), upadacitinib (avoid), live vaccines (avoid), varicella virus vaccine (avoid). Inactivated vaccines may have reduced response; give prior to start of therapy. Refer to package insert for further information.

SIDE EFFECTS

Alopecia; decreased albumin, calcium, glucose, phosphate, potassium, sodium, dehydration; edema; hyperglycemia; increased magnesium; pruritus; skin rash; xeroderma.

ANTIDOTE

Discontinue infusion and treat appropriately for severe hypersensitivity reactions.

SARGRAMOSTIM

(sar-**GRAM**-oh-stim)
Leukine
Colony-stimulating factor
Hematopoietic agent
pH 7.1 to 7.7

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Neutrophil recovery after induction chemotherapy in acute myelogenous leukemia (AML):

250 mcg/M^2/day as an infusion over 4 hours. Begin on Day 11 or 4 days after induction chemotherapy is complete. Day 10 bone marrow should be hypoplastic with fewer than 5% blasts. Repeat sargramostim daily until absolute neutrophil count (ANC) is greater than 1,500/mm^3 for 3 consecutive days or for a maximum of 42 days. Use same criteria if a second cycle of induction chemotherapy is indicated.

Autologous peripheral blood progenitor cell mobilization and collection:

250 mcg/M^2/day as a 24-hour continuous infusion (or give SC once daily). Continue at

the same dose until adequate numbers of progenitor stem cells are collected. Collection of progenitor cells (apheresis) usually begins about Day 5 and is repeated daily. All cells are stored until predetermined targets are achieved. Consider other mobilization therapy if adequate numbers of progenitor cells are not collected.

Autologous peripheral blood progenitor cell transplantation:

250 mcg/M^2/day as a 24-hour continuous infusion (or give SC once daily). Begin immediately after infusion of harvested progenitor cells and continue until ANC is greater than 1,500/mm^3 for 3 consecutive days.

Allogeneic or autologous bone marrow transplantation:

250 mcg/M^2/day as a 2-hour infusion daily. Begin 2 to 4 hours after bone marrow infusion and not less than 24 hours after the last dose of chemotherapy or radiation therapy. Do not administer sargramostim until the post–marrow infusion absolute neutrophil count (ANC) is less than 500 cells/mm^3. Continue until ANC is greater than 1,500/mm^3 for 3 consecutive days.

Allogeneic or autologous bone marrow transplantation: Treatment of delayed neutrophil recovery or graft failure:

250 mcg/M^2/day as a 2-hour infusion daily for 14 days. Dose can be repeated after 7 days off therapy if neutrophil recovery has not occurred. If neutrophil recovery has still not occurred, give a third 14-day course of 500 mcg/M^2/day after another 7 days off therapy. If there is still no improvement, it is unlikely that further dose escalation will be beneficial.

PEDIATRIC DOSE

Autologous peripheral blood progenitor cell transplantation, allogeneic or autologous bone marrow transplantation, allogeneic or autologous bone marrow transplantation (treatment of delayed neutrophil recovery or graft failure):

See Usual Dose.

DOSE ADJUSTMENTS

For ANC above 20,000 cells/mm^3 or WBC above 50,000 cells/mm^3, interrupt sargramostim treatment or reduce dose by one-half. ■ For Grade 3 or 4 adverse reactions, reduce dose by 50% or interrupt dosing until the reaction abates. ■ See Antidote.

DILUTION

Available as a liquid formulation preserved with benzyl alcohol (500-mcg multiple-dose vial) or as a lyophilized powder (250-mcg single-dose vial). Reconstitute each 250-mcg vial with 1 mL SWFI with or without preservative. Direct diluent to the side of the vial and swirl gently. Avoid foaming or vigorous agitation. Do not shake. Do not mix together the contents of vials reconstituted with different diluents. Either product must be further diluted in NS for infusion. If the final concentration of sargramostim will be below 10 mcg/mL, albumin (human) must be added to the NS before addition of the sargramostim (1 mL of 5% albumin to each 50 mL NS). This will prevent adsorption of the drug into the components of the IV delivery system. Solution should be clear and colorless.

Filters:

Manufacturer states, ***"Do not use an in-line membrane filter for IV infusion of sargramostim."***

Storage:

Must be refrigerated in all forms. Store in original carton to protect from light. Do not freeze or shake. Reconstituted product or any diluted solution should be used within 6 hours. Do not re-enter or reuse 250-mcg single-dose vial. Discard any unused portion. Liquid formulation can be refrigerated for up to 20 days after initial entry into vial.

COMPATIBILITY

Manufacturer recommends that no medication other than albumin be added to the infusion solution and that only NS be used to prepare IV solutions until specific **compatibility** data are available.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

See Usual Dose. Each single dose must be evenly distributed over 2, 4, or 24 hours. Do not use an in-line membrane filter. Reduce rate or temporarily discontinue for onset of any side effects that cause concern (e.g., hypersensitivity or infusion-related reactions).

ACTIONS

A human granulocyte-macrophage colony stimulating factor (rhu GM-CSF) produced by recombinant DNA technology. Induces partially committed progenitor cells to divide and differentiate in the granulocyte-macrophage pathways, which include neutrophils, monocytes/macrophages, and myeloid-derived dendritic cells. Is also capable of activating mature granulocytes and macrophages. Increases neutrophil, eosinophil, megakaryocyte, macrophage, and dendritic cell production. Reduces the duration of severe neutropenia. Mean terminal elimination half-life is approximately 3.84 hours.

INDICATIONS AND USES

To shorten time to neutrophil recovery and to reduce the incidence of severe, life-threatening, or fatal infections following induction chemotherapy in adult patients 55 years of age and older with acute myeloid leukemia (AML). ■ For the mobilization of hematopoietic progenitor cells into peripheral blood for collection by leukapheresis in adult patients with cancer undergoing autologous hematopoietic stem cell transplantation. ■ For the acceleration of myeloid reconstitution following autologous peripheral blood progenitor cell (PBPC) or bone marrow transplantation in adult and pediatric patients 2 years of age and older with non-Hodgkin lymphoma (NHL), acute lymphoblastic leukemia (ALL), and Hodgkin lymphoma (HL). ■ For the acceleration of myeloid reconstitution in adult and pediatric patients 2 years of age and older undergoing allogeneic bone marrow transplantation from HLA-matched related donors. ■ Treatment of adult and pediatric patients 2 years of age and older who have undergone allogeneic or autologous bone marrow transplantation in whom neutrophil recovery is delayed or failed. ■ To increase survival in adult and pediatric patients from birth to 17 years of age acutely exposed to myelosuppressive doses of radiation (hematopoietic syndrome of acute radiation syndrome [H-ARS]). Administered as a subcutaneous injection.

Unlabeled uses:

Primary prophylaxis of neutropenia in patients receiving chemotherapy (in settings other than transplant and AML) or who are at high risk for febrile neutropenia.

CONTRAINDICATIONS

History of serious hypersensitivity reactions, including anaphylaxis, to human granulocyte-macrophage colony-stimulating factor such as sargramostim or to any components of sargramostim or yeast-derived products.

PRECAUTIONS

Should be administered under the direction of a physician knowledgeable about appropriate use in a facility equipped to monitor the patient and respond to any medical emergency. ■ Due to the potential sensitivity of rapidly dividing hematopoietic progenitor cells, sargramostim should not be administered simultaneously with or within 24 hours preceding cytotoxic **chemotherapy** or **radiotherapy** or within 24 hours after chemotherapy. In one controlled trial, a higher incidence of adverse reactions, including higher mortality and a higher incidence of Grade 3 and 4 infections and Grade 3 and 4 thrombocytopenia, was observed. ■ Serious hypersensitivity reactions, including anaphylactic reactions, have been reported. ■ Sargramostim may cause infusion-related reactions, which usually occur after the first infusion in a particular cycle. These reactions may resolve with symptomatic treatment and usually do not recur with subsequent doses in the same cycle. ■ Edema, capillary leak syndrome, and pleural and/or pericardial effusions have been reported. Use with caution in patients with pre-existing fluid retention, pulmonary infiltrates, or congestive heart failure. Sargramostim may aggravate fluid retention in patients with pre-existing pleural and pericardial effusions. Fluid retention may be reversible after interruption or dose reduction with or without diuretic therapy. ■ Use with caution in patients with pre-existing cardiac disease. Supraventricular arrhythmias have been reported, particularly in patients with a previous history of cardiac arrhythmia. ■ Use caution if considered for use in any malignancy with myeloid characteristics. Can act as a growth factor for any tumor type, particularly myeloid malignancies. ■ Neutralizing antibodies may form after receiving sargramostim and may inhibit therapeutic effect. Incidence may be related to duration of exposure. Use sargramostim for the shortest duration required.

Monitor:

Obtain a CBC with differential before administration and twice weekly thereafter to monitor for excessive leukocytosis (WBC above 50,000 cells/mm^3; or an absolute neutrophil count [ANC] above 20,000 cells/mm^3). ■ If blast cells appear or disease progression occurs, treatment should be discontinued. ■ Anemia, leukocytopenia, and thrombocytopenia occur as side effects of various procedures; monitor carefully. ■ Monitor for S/S of a hypersensitivity reaction (e.g., anaphylaxis, generalized erythema, flushing, rash, urticaria). ■ Monitor for S/S of infusion-related reactions, particularly in patients with pre-existing lung disease. S/S may include dyspnea, flushing, hypotension, hypoxia, respiratory distress, syncope, and/or tachycardia. ■ Observe for fluid retention; may cause peripheral edema, pleural effusion, and/or pericardial effusion. Monitor body weight and hydration status.

Patient Education:

Read approved patient information guide. ■ Review medical history with health care provider. ■ Promptly report any signs or symptoms of infection (e.g., fever), infusion-related reactions, or hypersensitivity reactions (e.g., itching, swelling, redness at the injection site). ■ Promptly report weight gain, fluid retention, irregular heartbeat, pain, or other adverse reactions.

Maternal/Child:

Safety for use in pregnancy not established; use only if clearly needed. Use Leukine for injection (lyophilized product) reconstituted with SWFI without preservatives if use during pregnancy is required. ■ Avoid breast-feeding during treatment and for at least 2 weeks after the last dose of sargramostim. ■ Safety and effectiveness of sargramostim have been established in pediatric patients 2 years of age and older for autologous peripheral blood progenitor cells and bone marrow transplantation, allogeneic bone marrow transplantation, and treatment of delayed neutrophil recovery or graft failure. ■ Safety and effectiveness for these indications have not been established in pediatric patients under 2 years of age. ■ Safety and effectiveness for use in pediatric patients have not been established in AML or for autologous peripheral blood progenitor cell mobilization and collection. ■ Liquefied product contains benzyl alcohol. Exposure to benzyl alcohol has resulted in fatal adverse reactions, including “gasping syndrome” in neonates and low-birth-weight infants. Syndrome is characterized by CNS depression, metabolic acidosis, and gasping respirations. Leukine for injection (lyophilized product) reconstituted with SWFI without preservatives should be used for neonates and infants.

DRUG/LAB INTERACTIONS

Do not administer simultaneously with or within 24 hours preceding cytotoxic **chemotherapy** or **radiotherapy** or within 24 hours following chemotherapy. Rapidly dividing cells and the success of the treatment would be adversely affected by chemotherapy and radiation. ■ Myeloproliferative effects may be potentiated by **lithium or corticosteroids;** avoid use if possible. If concurrent use cannot be avoided, monitor for clinical and laboratory signs of myeloproliferative effects.

SIDE EFFECTS

Autologous BMT:

The most commonly reported adverse reactions include alopecia, anorexia, asthenia, diarrhea, edema, fever, gastrointestinal disorder, malaise, mucous membrane disorder, nausea, rash, and vomiting. Other reported reactions include GI hemorrhage, liver damage, sepsis, and stomatitis.

Allogeneic BMT:

The most commonly reported adverse reactions include abdominal pain, alopecia, anorexia, diarrhea, fever, headache, high glucose, hypertension, low albumin, nausea, rash, stomatitis, and vomiting. Other reported reactions include asthenia, chest pain, chills, dyspepsia, and pain.

AML:

The most commonly reported adverse reactions include alopecia, diarrhea, fever, genitourinary abnormalities, infections, liver toxicity, metabolic laboratory abnormalities, nausea, neurotoxicity, pulmonary toxicity, skin reactions, stomatitis, vomiting, and weight loss. Other reported reactions include anorexia, chills, hypersensitivity reactions, and neuromotor and neuropsychiatric reactions.

Post-Marketing:

Capillary leak syndrome, effusions, hypersensitivity reactions, immunogenicity, infusion-related reactions, injection site reactions, leukocytosis (including eosinophilia), pain (including abdominal, back, chest, and joint pain), supraventricular arrhythmias, and thromboembolic events.

Overdose:

Chills, dyspnea, fever, headache, leukocytosis, malaise, nausea, rash, sinus tachycardia.

ANTIDOTE

Keep physician informed of all side effects. Most may be treated symptomatically, with temporary interruption of therapy or with a dose or rate reduction; see Dose Adjustments. Discontinue sargramostim for leukemic regrowth, if blast cells appear, or if there is progression of underlying disease. A maximum dose limit has not been determined; for accidental overdose, discontinue and monitor for WBC increase and respiratory symptoms. For ANC above 20,000 cells/mm^3 or WBC above 50,000 cells/mm^3, reduce dose by one-half or temporarily discontinue. Blood cell count should return to baseline level in 3 to 7 days. For any side effect that causes concern, reduce dose or temporarily discontinue. Dose reduction or interruption, with or without diuretic therapy, may reverse fluid retention. Infusion-related reactions may resolve with symptomatic treatment or by decreasing the rate of the infusion by 50%. If symptoms persist or worsen despite rate reduction, discontinue the infusion. May be able to administer subsequent infusions following the standard dose schedule with careful monitoring. Discontinue sargramostim permanently for serious hypersensitivity reactions. Treat as indicated and resuscitate as necessary.

SEBELIPASE ALFA

(se-be-**LYE**-pase **AL**-fa)
Kanuma
Enzyme replenisher
pH 5.9

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Patients with rapidly progressive lysosomal acid lipase (LAL) deficiency presenting within the first 6 months of life:

1 mg/kg administered once each week as an infusion. For patients who do not achieve an optimal clinical response, increase to 3 mg/kg once each week.

Pediatric and adult patients with LAL deficiency:

1 mg/kg administered once every other week as an infusion.

DOSE ADJUSTMENTS

See Usual Dose.

DILUTION

Available as a single-use vial containing 20 mg/10 mL. Calculate the dose (mg) based on actual body weight, total volume (mL) of solution required, and number of vials required using the following calculations:

(Weight in kg × Dose/kg) ÷ 20 mg/vial = # of vials required

Round to the next whole vial. Remove from the refrigerator and allow to come to room temperature.

For a 50-kg patient: [(50 kg) × (1 mg/kg)] ÷ 20 mg/vial = 2.5 vials

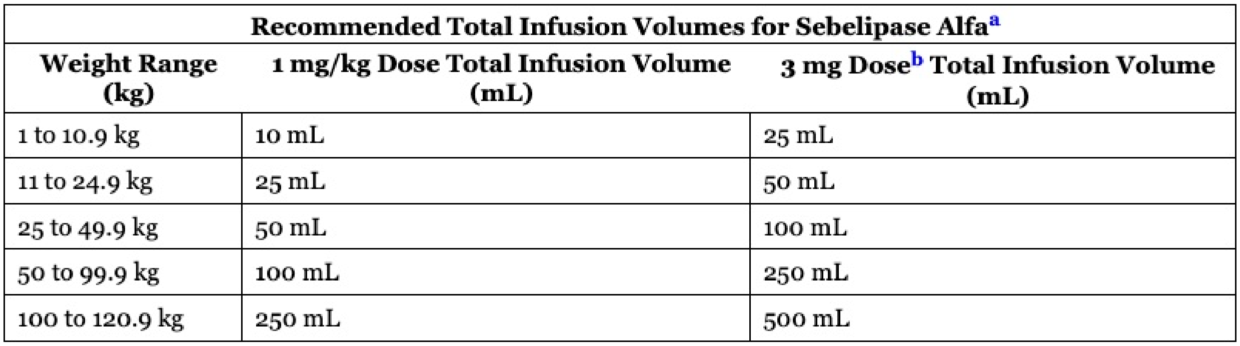
For a 10-kg patient: [(10 kg) × (3 mg/kg)] ÷ 20 mg/vial = 1.5 vials

Solution should be clear to slightly opalescent and colorless to slightly colored. Thin, translucent particles or fibers may be present in vials or diluted solution. Do not use if solution is cloudy or if other particulate matter is observed. Withdraw the calculated dose (50 mg [25 mL] in the 1-mg/kg example, and 30 mg [15 mL] in the 3-mg/kg example) and further dilute with NS:

Volume of NS for dilution = Total infusion volume (mL) for patient’s weight (see chart)

– Volume (mL) of calculated total dose

Mix gently by inversion. ***Do not shake*** the vials or the prepared infusion. See the following chart for examples of total infusion volumes.



Recommended Total Infusion Volumes for Sebelipase Alfa[a]		
Weight Range (kg)	**1 mg/kg Dose Total Infusion Volume (mL)**	**3 mg Dose[b] Total Infusion Volume (mL)**
1 to 10.9 kg	10 mL	25 mL
11 to 24.9 kg	25 mL	50 mL
25 to 49.9 kg	50 mL	100 mL
50 to 99.9 kg	100 mL	250 mL
100 to 120.9 kg	250 mL	500 mL

[a] Infusion volume should be based on the prescribed dose and should be prepared to a final sebelipase alfa concentration of 0.1 mg/mL to 1.5 mg/mL.

[b] For patients with LAL deficiency presenting within the first 6 months of life who do not achieve an optimal clinical response with a dose of 1 mg/kg.

Filters:

Must be administered through a low–protein-binding infusion set with an in-line, low–protein-binding, 0.2-micron filter.

Storage:

Refrigerate at 2° to 8° C (36° to 46° F) in original carton to protect from light. Do not freeze or shake the vials. The diluted product should be used immediately but may be stored for up to 24 hours if refrigerated and protected from light. Do not freeze or shake. Discard any unused product.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

For IV infusion only. Use of a low–protein-binding infusion set with an in-line, low–protein-binding, 0.2-micron filter required. Administer the total infusion over at least 2 hours. Infusion time may be further prolonged for patients receiving the 3-mg/kg dose or for those who have experienced hypersensitivity reactions. Lower the infusion rate or interrupt the infusion as indicated for infusion reactions; see Antidote. A 1-hour infusion may be considered for patients receiving the 1-mg/kg dose who tolerate the infusion.

ACTIONS

Sebelipase alfa is a recombinant human lysosomal acid lipase (rhLAL). It is produced by recombinant DNA technology in the whites of eggs laid by genetically engineered chickens. LAL deficiency is an autosomal recessive lysosomal storage disorder characterized by a genetic defect that results in a marked decrease or loss in activity of the lysosomal acid lipase enzyme. The primary site of action of the LAL enzyme is the lysosome, where the enzyme normally causes the breakdown of lipid particles. Deficient LAL enzyme activity results in progressive complications due to the lysosomal accumulation of cholesteryl esters and triglycerides in multiple organs, including the liver, spleen, intestine, and walls of blood vessels. The resulting lipid accumulation in the liver may lead to increased liver fat content and progression of liver disease, including fibrosis and cirrhosis. Lipid accumulation in the intestinal wall leads to malabsorption and growth failure. Dyslipidemia due to impaired degradation of lysosomal lipids is common with elevated LDL cholesterol and triglycerides and with low HDL cholesterol. Sebelipase alfa binds to cell surface receptors expressed on the protein and is internalized into lysosomes. It catalyzes the hydrolysis of cholesteryl esters and triglycerides to free cholesterol, glycerol, and free fatty acids. In clinical trials, there was an increase in LDL cholesterol and triglycerides following initiation of therapy as accumulated lysosomal lipids were broken down. However, within 8 weeks of initiating therapy, these parameters decreased to below pretreatment values. In patients with elevated ALT values at baseline, reductions in ALT were seen within 2 weeks following the start of treatment. Half-life of sebelipase alfa is 5.4 minutes in pediatric patients and 6.6 minutes in adults.

INDICATIONS AND USES

Treatment of patients with a diagnosis of lysosomal acid lipase (LAL) deficiency.

CONTRAINDICATIONS

Manufacturer states, “None”; see Precautions.

PRECAUTIONS

For IV infusion only. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Can cause severe hypersensitivity reactions. The majority of reactions occurred during or within 4 hours of completion of the infusion. Anaphylaxis has occurred as early as the sixth infusion and as late as 1 year after treatment initiation. ■ Produced in egg whites; consider the risks and benefits of treatment in patients with known hypersensitivity reactions to eggs or egg products. ■ As with all therapeutic proteins, there is the potential for immunogenicity.

Monitor:

Obtain baseline CBC with differential, lipid panel, and liver enzyme studies and monitor as indicated during therapy. ■ Monitor vital signs. ■ Monitor for S/S of hypersensitivity reactions. Patients experiencing anaphylaxis presented with S/S that included chest discomfort, dyspnea, generalized and itchy rash, hyperemia, rhinorrhea, severe respiratory distress, swelling of eyelids, tachycardia, tachypnea, and urticaria. Other S/S related to hypersensitivity reactions included abdominal pain, agitation, chills, diarrhea, eczema, edema, fever, hypertension, irritability, laryngeal edema, nausea, pallor, pruritus, and vomiting. ■ Observe patients closely during and after the infusion. Immediately slow or interrupt the infusion for hypersensitivity reactions of any grade/severity; see Antidote. Pretreatment with antipyretics and/or antihistamines may prevent subsequent reactions if symptomatic treatment was required.

Patient Education:

Immediately report any S/S of hypersensitivity reactions (e.g., chills; cough; difficulty breathing; headache; itchy, runny, or blocked nose).

Maternal/Child:

Use during pregnancy only if clearly needed. Animal reproductive studies showed no evidence of embryolethality, fetotoxicity, teratogenicity, or abnormal early embryonic development. ■ Safety for use during breast-feeding is unknown. ■ Safety and effectiveness for use in pediatric patients age 1 month and older have been established.

Elderly:

Clinical trials did not include any patients age 65 years or older. It is not known whether they respond differently than younger patients.

DRUG/LAB INTERACTIONS

No drug interaction studies have been performed.

SIDE EFFECTS

Patients with rapidly progressive disease presenting within the first 6 months of life:

Anemia, cough, diarrhea, fever, nasopharyngitis, rhinitis, urticaria, and vomiting were most common.

Pediatric and adult patients:

Asthenia, constipation, fever, headache, nasopharyngitis, nausea, and oropharyngeal pain were most common.

Both diagnoses:

Increases in LDL cholesterol and triglycerides (with initial treatment) and severe hypersensitivity reactions have occurred.

ANTIDOTE

Keep physician informed of side effects; most will be treated symptomatically. Management of hypersensitivity reactions should be based on the severity of the reaction and may include temporarily interrupting the infusion, lowering the infusion rate, and or treatment with antihistamines (e.g., diphenhydramine), antipyretics (e.g., acetaminophen), and/or corticosteroids (e.g., hydrocortisone). If interrupted, the infusion may be resumed at a slower rate with increases as tolerated. With additional premedication and/or a reduction in the rate of infusion, patients may be able to continue treatment. If a severe hypersensitivity or anaphylactic reaction occurs, discontinue sebelipase alfa immediately and treat with oxygen, epinephrine, antihistamines, vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Consider the risk versus benefit of readministering sebelipase alfa following a severe reaction. If the decision is made to readminister the product, monitor the patient closely with emergency equipment readily available.

SECRETIN (HUMAN) ■ SECRETIN (PORCINE)

(si-**KRET**-in)
ChiRhoStim ■ Generic
Diagnostic agent
pH 3 to 6.5

USUAL DOSE

Preparation before secretin stimulation testing:

To avoid an incorrect stimulation test result, **discontinue the following drugs** before administration of secretin: Discontinue anticholinergic drugs (at least 5 half-lives before testing), H_2-receptor antagonists (at least 2 days before testing), and proton pump inhibitors (PPIs); consult the prescribing information for specific PPIs; see Drug/Lab Interactions. A fast of at least 12 to 15 hours is required before certain tests; see Patient Education.

The recommended dose regimen of secretin by indication is presented in the following chart.

Secretin (porcine) test dose:

0.2 mcg IV. If no hypersensitivity reaction occurs in 1 minute, administer diagnostic dose. An IV test dose is not required for the secretin (human) formulation.

Secretin Dose by Indication

Indication	Recommended Dose
Stimulation of pancreatic secretions, including bicarbonate, to aid in the diagnosis of exocrine pancreas dysfunction	0.2 mcg/kg by IV injection over 1 minute
Stimulation of gastrin secretion to aid in the diagnosis of gastrinoma	0.4 mcg/kg by IV injection over 1 minute
Stimulation of pancreatic secretions to facilitate identification of the ampulla of Vater and accessory papilla during endoscopic retrograde cholangiopancreatography (ERCP)	0.2 mcg/kg by IV injection over 1 minute

DILUTION

Available in single-dose vials containing either 16 mcg or 40 mcg (secretin [human]) or

16 mcg (secretin [porcine]). Determine the number of vials needed for the prescribed dose based on the patient's weight and recommended dose. Confirm mcg/vial before reconstitution and administration.

To determine patient dose:

Total dose (mcg) = Patient's weight (kg) × Prescribed dose (mcg/kg)

Reconstitute each vial containing 16 mcg of secretin with 8 mL of NS (2 mcg/mL).

Reconstitute each vial containing 40 mcg with 10 mL of NS (4 mcg/mL).

Shake both concentrations vigorously to ensure dilution. Reconstitute the correct number of vials to supply the total dose.

Storage:

Store lyophilized product in the freezer at −20° C (−4° F). Protect from light. Do not use beyond expiration date on vial. Use diluted solution immediately and discard unused portion.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Diagnostic dose:

A single dose as an IV injection evenly distributed over 1 minute.

ACTIONS

An acetate salt of secretin, a peptide hormone. Its primary action is to stimulate pancreatic ductal cells to secrete pancreas fluid in large volumes that contain bicarbonate. Also facilitates the identification of the ampulla of Vater and the accessory papilla during endoscopic retrograde cholangiopancreatography (ERCP) to assist in cannulation of the pancreatic ducts. After a bolus injection, concentrations of secretin declined to baseline concentrations within 90 to 120 minutes. Elimination half-life is 27 minutes (porcine) or 45 minutes (human).

INDICATIONS AND USES

Stimulation of pancreatic secretions, including bicarbonate, to aid in the diagnosis of pancreatic exocrine dysfunction. ■ Stimulation of gastrin secretion to aid in the diagnosis of gastrinoma. ■ Stimulation of pancreatic secretions to facilitate identification of the ampulla of Vater and accessory papilla during ERCP.

CONTRAINDICATIONS

Secretin (human):

None.

Secretin (porcine):

Documented hypersensitivity to porcine products or hypersensitivity reaction to the test dose.

PRECAUTIONS

Secretin (porcine):

Because of a potential hypersensitivity reaction, all patients should receive an IV test dose; see Usual Dose. This test dose is especially important in patients with a history of atopy. Administer in a facility equipped to handle medical emergencies. Appropriate measures for the treatment of acute hypersensitivity reactions should be immediately available.

Both products:

Stimulation testing with secretin should be performed only by physicians with sufficient expertise. Ensure that the institution has established normative ranges for pancreatic exocrine response. ■ Patients who have undergone a vagotomy, are receiving anticholinergic agents (e.g., atropine, glycopyrrolate), or have inflammatory bowel disease may be hyporesponsive to secretin stimulation, falsely suggesting pancreatic disease. ■ Patients with alcoholic or other liver disease may be hyperresponsive to stimulation with secretin, masking the presence of coexisting pancreatic disease. Consider additional testing and clinical assessments to aid in diagnosis in patients who may be hyporesponsive or hyperresponsive to secretin stimulation.

Monitor:

Monitor for S/S of hypersensitivity (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing). ■ See prescribing information for specific sample collection methods, timing of samples or blood draws, handling of specimens, and interpretation of test results.

Patient Education:

Before testing, review all medications with your health care provider. ■ Promptly report S/S of a hypersensitivity reaction (e.g., light-headedness, rash, urticaria, tightness of the chest, wheezing). ■ A fast of at least 12 to 15 hours is required before certain tests. Review requirements with provider.

Maternal/Child:

Use during pregnancy only if clearly needed. Safety not established, and fluoroscopy may be required. ■ Use caution during breast-feeding; effect on the breast-fed infant or on milk production not known. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Safety, pharmacologic response, and diagnostic effectiveness similar to younger patients. Greater sensitivity of older patients cannot be ruled out.

DRUG/LAB INTERACTIONS

Concomitant use of **anticholinergic agents** (e.g., atropine, glycopyrrolate) may cause a hyporesponse to stimulation testing with secretin. Discontinue anticholinergic drugs at least 5 half-lives before administering secretin. ■ Concomitant use of **H_2-receptor antagonists** or **PPIs** may cause a hyperresponse in gastrin secretion in response to stimulation testing with secretin, falsely suggesting gastrinoma. Discontinue H_2-receptor antagonists at least 2 days before administering secretin to aid in the diagnosis of gastrinoma. The time it takes for serum gastrin concentrations to return to baseline after discontinuation of PPIs is specific to the individual drug. Consult the prescribing information of each PPI before administering secretin to aid in the diagnosis of gastrinoma.

SIDE EFFECTS

The most common adverse reactions include nausea, vomiting, flushing, and upset stomach.

ANTIDOTE

Discontinue the drug immediately for any signs of a hypersensitivity reaction. Treat anaphylaxis with epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), aminophylline, and corticosteroids as indicated. Maintain a patent airway and resuscitate as necessary.

SERMORELIN ACETATE

(**SER**-moe-reh-lin **AS**-ah-tayt)
Geref
Hormone
Diagnostic agent
pH 5.5

USUAL DOSE

1 mcg/kg of body weight as a single test dose. Schedule in the morning following an overnight fast. Specific procedure required. Draw venous blood samples for growth hormone determinations 15 minutes before administration, immediately before administration, and every 15 minutes times four after administration. Use a 3-mL NS flush immediately after injection of sermorelin.

DILUTION

Each 50-mcg ampule must be reconstituted with a minimum of 0.5 mL of the 2 mL NS provided. Solution must be clear and used immediately after reconstitution.

Do not use if cloudy or discolored. Discard any unused material.

Storage:

Dry powder stable for 1 year from date of manufacture if stored in refrigerator.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as a bolus injection followed by a 3-mL NS flush.

ACTIONS

A sterile, lyophilized white powder, this synthetic hormone is identical in amino acid composition to endogenous natural growth hormone-releasing factor (GHRF, GRF). Increases plasma growth hormone concentrations by direct stimulation of the somatotroph cells of the anterior pituitary gland to release growth hormone. Does not have stimulatory effects on the secretion of other pituitary hormones (e.g., prolactin, TSH, FSH, LH, or ACTH). An increase in peak levels begins within 5 minutes, and maximum levels occur 30 to 60 minutes after injection. Plasma half-life is 6 to 8 minutes. Rapidly distributed and then degraded to an inactive fragment.

INDICATIONS AND USES

Evaluation of the ability of the somatotroph of the pituitary gland to secrete growth hormone (GH). ■ Used SC for treatment of idiopathic growth hormone deficiency in pediatric patients with growth failure and as an adjunct to gonadotropin therapy in ovulation induction for infertility (orphan designation).

CONTRAINDICATIONS

Hypersensitivity to sermorelin acetate or any of its components (e.g., mannitol, albumin).

PRECAUTIONS

A normal plasma GH response (28 +/− 15 ng/mL within 30 minutes) to sermorelin acetate demonstrates that the somatotroph is intact. 50% of patients who do not respond to standard testing will show a normal response to sermorelin. GH deficiency may still be the result of hypothalamic dysfunction in the presence of an intact somatotroph. ■ Test is most easily interpreted when there is a subnormal response to conventional provocative testing and a normal response to sermorelin. The site of dysfunction cannot be determined if both conventional and sermorelin testing result in subnormal GH responses. ■ Not useful in the diagnosis of acromegaly. ■ Discontinue exogenous growth hormone therapy at least 1 week before testing. ■ Response may be inhibited by obesity, hyperglycemia, and elevated plasma fatty acids.

Monitor:

See Precautions and Drug/Lab Interactions.

Maternal/Child:

Safety for use in pregnancy and lactation not established. Has been shown to produce minor variations in fetuses of rats and rabbits. Use during pregnancy or lactation only if benefits outweigh risk.

DRUG/LAB INTERACTIONS

Do not test in the presence of **drugs that directly affect the pituitary secretion of somatotropin** (e.g., insulin, glucocorticoids [e.g., dexamethasone, cortisone, prednisone], cyclooxygenase inhibitors [e.g., aspirin or indomethacin]). ■ Transiently elevated somatotropin levels can occur with **clonidine, levodopa, and insulin-induced hypoglycemia.** ■ Response inhibited by **muscarinic antagonists** (e.g., atropine), **antithyroids** (e.g., propylthiouracil), **and in hypothyroid patients.**

SIDE EFFECTS

Average dose:

Hypersensitivity reactions (e.g., redness, swelling, and urticaria at the injection site [25% of patients develop antibodies]); flushing of the face; headache; nausea; pain at the injection site; paleness; strange taste in the mouth; tightness in the chest; transient warmth; vomiting.

Overdose:

Blood pressure and heart rate changes have been reported with doses over 10 mcg/kg. Cardiovascular collapse is conceivable but has not happened.

ANTIDOTE

Notify physician of all side effects; may be transient or may require symptomatic treatment. Treat hypersensitivity reactions with diphenhydramine or epinephrine. Resuscitate as necessary.

SILDENAFIL BBW *

(sil-**DEN**-a-fil)
Revatio
Vasodilating agent
Antihypertensive (pulmonary)

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Sildenafil:

2.5 mg (3.125 mL) or 10 mg (12.5 mL) as an IV bolus 3 times daily. Administer doses 4 to 6 hours apart. A 10-mg IV dose of sildenafil is equivalent to a 20-mg oral dose. Resume oral therapy as soon as tolerated. In a study evaluating lower doses, there were no significant differences in the effects on hemodynamic variables compared with higher doses. Treatment with doses higher than 10 mg IV (20 mg PO) three times a day is not recommended.

DOSE ADJUSTMENTS

No dose adjustments required for age, gender, race, weight, renal impairment (mild, moderate, or severe), or hepatic impairment (mild or moderate). Has not been studied in patients with severe hepatic impairment.

DILUTION

May be given undiluted. Aseptically withdraw the dose directly into a syringe for immediate use.

Filters:

Specific information not available.

Storage:

Store vials at CRT.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an IV bolus.

ACTIONS

An inhibitor of cGMP-specific phosphodiesterase type 5 (PDE5) in the smooth muscle of the pulmonary vasculature where PDE5 is responsible for degradation of cGMP. Sildenafil increases cGMP within pulmonary vascular smooth muscle cells, resulting in relaxation. In patients with pulmonary arterial hypertension, this can lead to vasodilation of the pulmonary vascular bed and, to a lesser degree, vasodilation in the systemic circulation. PDE5 is also found in other tissues, including vascular and visceral smooth muscle, and in platelets. Sildenafil and its major metabolite are approximately 96% protein bound. Metabolized in the liver predominantly by CYP3A4 and other hepatic microsomal isoenzymes. Terminal half-life is about 4 hours. Findings suggest a lower clearance and/or a higher bioavailability of sildenafil in patients with pulmonary arterial hypertension compared with healthy volunteers. Primarily excreted in feces and approximately 13% in urine.

INDICATIONS AND USES

Treatment of pulmonary arterial hypertension (PAH) (WHO Group 1) in patients who are currently prescribed oral sildenafil and are temporarily unable to take oral medications. Intended to improve exercise ability and delay clinical worsening. Delay in clinical worsening demonstrated with concurrent use of epoprostenol (Flolan). Studies establishing effectiveness included predominantly patients with NYHA Functional Class II-III symptoms and idiopathic etiology or etiology associated with connective tissue disease.

Limitation of use:

Adding sildenafil to bosentan (Tracleer) therapy in the treatment of PAH does not result in any beneficial effect on exercise capacity.

CONTRAINDICATIONS

Known hypersensitivity to sildenafil or any component of the product. ■ Concomitant use of organic nitrates in any form, either regularly or intermittently, because of the greater risk of hypotension. ■ Concomitant use of riociguat, a guanylate cyclase stimulator. PDE5 inhibitors, including sildenafil, may potentiate the hypotensive effects of riociguat.

PRECAUTIONS

Has vasodilatory properties, resulting in mild and transient decreases in BP. Use with caution in patients with resting hypotension (BP less than 90/50 mm Hg), fluid depletion, severe left ventricular outflow obstruction, autonomic dysfunction, and in patients undergoing antihypertensive therapy. ■ Increase in mortality with increasing dose noted in pediatric patients; see Maternal/Child. ■ Not recommended for use in patients with pulmonary veno-occlusive disease (PVOD); it may significantly worsen their cardiac status. Consider the possibility of associated PVOD if signs of pulmonary edema occur. ■ Epistaxis has been reported in patients with PAH secondary to connective tissue disease (CTD) and in patients treated with concomitant warfarin. ■ Safety for use in patients with bleeding disorders or active peptic ulceration is unknown. ■ Sudden loss of vision in one or both eyes has been reported. Nonarteritic anterior ischemic optic neuropathy (NAION), a cause of decreased vision (including permanent loss of vision), has been reported in temporal association with PDE5 inhibitors. Most, but not all, of these patients had underlying anatomic or vascular risk factors for developing NAION. A causal relationship between PDE5 inhibitor use and NAION has not been fully substantiated. ■ Use with caution in patients with retinitis pigmentosa. ■ Sudden decrease or loss of hearing has been reported; may be accompanied by dizziness and tinnitus. ■ Use with caution in patients with an anatomic deformation of the penis (e.g., angulation, cavernosal fibrosis, or Peyronie's disease) or in patients with conditions that may predispose them to priapism (e.g., sickle cell anemia, multiple myeloma, or leukemia). Penile tissue damage and permanent loss of potency can result from priapism lasting more than 6 hours. ■ Effectiveness and safety of sildenafil in PAH secondary to sickle cell anemia have not been established. Increased incidence of vaso-occlusive crisis requiring hospitalization has been reported in this patient population. ■ See Drug/Lab Interactions.

Monitor:

Obtain baseline studies as indicated by specific patient history. ■ Monitor VS closely to note unsafe drops in BP. Monitoring of BP is especially important when sildenafil is coadministered with other BP-lowering drugs. ■ Monitor for vision and/or hearing loss. ■ See Precautions, Patient Education, and Drug/Lab Interactions.

Patient Education:

Read manufacturer's patient education booklet carefully. ■ Never take sildenafil with nitrate medicines or guanylate cyclase stimulators (e.g., riociguat [Adempas]); may cause a sudden and unsafe drop in BP. ■ Do not take Viagra or other similar medications for erectile dysfunction with sildenafil. ■ Seek immediate medical attention with a sudden loss of vision in one or both eyes. ■ Seek prompt medical attention in the event of a sudden decrease or loss of hearing. ■ Seek emergency help if an erection lasts for more than 4 hours. ■ Discuss medications (prescription, nonprescription, and herbal) with a health care professional; see Drug/Lab Interactions.

Maternal/Child:

Limited data show no clear association between sildenafil and major birth defects, miscarriage, or adverse maternal or fetal outcomes when used during pregnancy. ■ Pregnant women with untreated pulmonary arterial hypertension are at risk for heart failure, stroke, preterm delivery, and maternal and fetal death. ■ Insufficient information about the effects of sildenafil on the breast-fed infant and no information on the effects of sildenafil on milk production. ■ Use in pediatric patients, particularly chronic use, is not recommended. In a long-term study, mortality increased; deaths were first observed after about 1 year.

Elderly:

Major differences in response compared with younger adults have not been identified; however, healthy elderly volunteers had a reduced clearance resulting in higher plasma concentrations. Dosing should be cautious. Consider age-related organ impairment and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

Sildenafil is also marketed as Viagra. Do not take **Viagra or other PDE5 inhibitors** (e.g., tadalafil, vardenafil) concurrently with sildenafil. ■ Potentiates the hypotensive effects of nitrates. Concurrent use with **nitrates** in any form is ***contraindicated*** (e.g., nitroglycerin in any form, isosorbide mononitrate, isosorbide dinitrate, street drugs called "poppers" [amyl nitrate or nitrite]). May result in an unsafe drop in BP. ■ Concurrent use with **riociguat** is ***contraindicated***. ■ Concurrent use with **alpha-adrenergic blocking agents** can lower BP significantly and lead to symptomatic hypotension. BP may be lowered further with this combined use of vasodilators by other variables, including intravascular volume depletion and concomitant use of other **antihypertensive drugs**. Monitor BP when coadministering blood pressure–lowering drugs with sildenafil. ■ Concomitant use of sildenafil with **ritonavir and other potent CYP3A4 inhibitors** (e.g., atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, saquinavir, and voriconazole) ***is not recommended.*** ■ **Cimetidine** and **erythromycin** may cause an increase in sildenafil plasma concentrations. ■ **Potent CYP3A4 inducers** (e.g., carbamazepine, dexamethasone, phenytoin, phenobarbital, rifabutin, rifapentine, rifampin, and St. John's wort) may increase sildenafil clearance and reduce its effectiveness. ■ **Bosentan** may increase sildenafil clearance; see Limitation of Use.

SIDE EFFECTS

The most common side effects are dyspepsia, dyspnea, epistaxis, erythema, flushing, headache, insomnia, and rhinitis. Serious side effects include hearing loss, hypotension, priapism, vaso-occlusive crisis, and vision loss. Other side effects reported include diarrhea, fever, gastritis, myalgia, paresthesia, and sinusitis. Additional adverse effects seen when sildenafil is administered in combination with epoprostenol (Flolan) include edema (including peripheral edema), nasal congestion, nausea, and pain in extremities. Retinal hemorrhage occurred in patients with risk factors for hemorrhage, including concurrent anticoagulant therapy.

Post-Marketing:

Serious cardiovascular, cerebrovascular, and vascular events, including MI, cerebrovascular hemorrhage, hypertension, pulmonary hemorrhage, subarachnoid and intracerebral hemorrhages, TIA, ventricular arrhythmia, and sudden cardiac death have occurred at doses indicated for erectile dysfunction. NAION (with decreased vision, including permanent vision loss); sudden decrease or loss of hearing; seizure; and seizure recurrence.

ANTIDOTE

Treatment of most side effects will be supportive. Notify physician immediately if a serious side effect occurs (e.g., hearing loss, hypersensitivity, hypotension, priapism, vision loss). Treat hypersensitivity reactions with epinephrine, antihistamines, and corticosteroids as needed. Hemodialysis is not expected to be effective in overdose.

SILTUXIMAB

Sylvant
Monoclonal antibody
Interleukin-6 (IL-6) antagonist
pH 5.2

USUAL DOSE

Pretreatment:

Absolute neutrophil count (ANC), platelet count, and hemoglobin testing required before each dose for the first 12 months and every 3 dosing cycles thereafter; see Monitor. See Maternal/Child.

Treatment criteria are outlined in the following chart. If criteria are not met, consider delaying treatment. ***Do not reduce dose.***

Siltuximab Treatment Criteria		
Laboratory Parameter	**Requirements Before the First Siltuximab Infusion**	**Retreatment Criteria for Every-3-Week Infusions**
Absolute neutrophil count	≥1 × 10^9/L	≥1 × 10^9/L
Platelet count	≥75 × 10^9/L	≥50 × 10^9/L
Hemoglobin	<17 Gm/dL	<17 Gm/dL

Siltuximab:

11 mg/kg as an IV infusion equally distributed over 1 hour. Administer every 3 weeks until treatment failure.

DOSE ADJUSTMENTS

No initial dosage adjustment is necessary for patients with CrCl greater than or equal to 15 mL/min. ■ No initial dosage adjustment is necessary for patients with mild to moderate hepatic impairment.

DILUTION

Siltuximab is available as a lyophilized powder in 100-mg and 400-mg single-use vials for intravenous infusion. Determine the number of vials required using the following calculations:

Weight in kg × Dose/kg ÷ 100 or 400 mg/vial = # of vials required

A 60-kg man requiring 11 mg/kg would require 660 mg. 660 mg ÷ 100 mg/vial = 6.6 (÷ 400 mg/vial = 1.65) vials required. After patient is weighed and appropriate dose is calculated, remove vials from the refrigerator and allow to come to RT for 30 minutes. Use of a 21-gauge 1½-inch needle is recommended for preparation. Aseptically reconstitute each siltuximab vial as instructed in the following chart.

Instructions for Reconstituting Vials of Siltuximab		
Strength	**Amount of SWFI Required**	**Postreconstitution Concentration in mg/mL**
100-mg vial	5.2 mL	20 mg/mL
400-mg vial	20 mL	20 mg/mL

Gently swirl reconstituted vials. ***Do Not Shake or Swirl Vigorously.*** Powder may take up to 60 minutes to dissolve. Must be further diluted for infusion within 2 hours of the initial reconstitution. Maintain at RT. Do not use if particles or solution discoloration is present or if solution is visibly opaque. To further dilute, withdraw a volume of D5W equal to the calculated volume of the siltuximab dose from a 250-mL infusion bag of D5W and slowly add the siltuximab solution. Gently invert to mix the solution. Infusion bags must be made of either polyvinyl chloride (PVC), polyolefin (PO), polypropylene (PP), or polyethylene (PE). Alternatively, PE bottles may be used.

Filters:

Use of a 0.2-micron in-line polyethersulfone (PES) filter required.

Storage:

Store unopened vials refrigerated at 2° to 8° C (36° to 46° F) in original cartons to protect from light. Do not freeze. Do not use beyond expiration date located on the carton and vial. Does not contain preservatives. Complete infusion within 4 hours of dilution. Discard any unused portion of the reconstituted product or the infusion solution. Waste material should be disposed of in accordance with local requirements.

COMPATIBILITY

Manufacturer states, "Do not infuse siltuximab concomitantly in the same intravenous line with other agents." **Compatible** only with infusion bags of polyvinyl chloride (PVC), polyolefin (PO), polypropylene (PP), or polyethylene (PE), and administration sets lined with PVC, polyurethane (PU), or PE.

RATE OF ADMINISTRATION

A single dose equally distributed over 1 hour as an IV infusion. Stop the infusion if the patient develops a mild to moderate infusion reaction. If the reaction resolves, siltuximab may be restarted at a lower infusion rate. Consider premedication with antihistamines, acetaminophen, and corticosteroids as indicated. Discontinue siltuximab if patient does not tolerate the infusion following these interventions. Complete infusion within 4 hours of dilution.

ACTIONS

Siltuximab is a human-mouse chimeric monoclonal antibody produced by Chinese hamster ovary cells. It binds human interleukin-6 (IL-6) and prevents the binding of IL-6 to both soluble and membrane-bound IL-6 receptors. Overproduction of IL-6 has been linked to systemic manifestations in patients with multicentric Castleman's disease (MCD). With the first infusion, peak serum concentration occurs close to the end of the infusion. With the once-every-3-week dosing regimen, siltuximab steady-state is achieved by the sixth infusion. The mean terminal half-life for siltuximab in patients after the first infusion is 20.6 days (range 14.2 to 29.7 days).

INDICATIONS AND USES

Treatment of patients with multicentric Castleman's disease (MCD) who are human immunodeficiency virus (HIV) negative and human herpesvirus-8 (HHV-8) negative.

Limitation of use:

Siltuximab was not studied in patients with MCD who are HIV-positive or HHV-8 positive because siltuximab did not bind to virally produced IL-6 in a nonclinical study.

CONTRAINDICATIONS

Severe hypersensitivity to siltuximab or any of its excipients.

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Do not administer siltuximab to patients with severe infections until the infection resolves. May mask S/S of acute inflammation, including suppression of fever and of acute-phase reactants such as C-reactive protein (CRP). ■ Hypersensitivity and/or infusion reactions, including anaphylaxis, have been reported. ■ Do not administer live virus vaccines to patients receiving siltuximab. IL-6 inhibition may interfere with the normal immune response to new antigens. ■ Use with caution in patients who may be at increased risk for GI perforation. ■ May increase hemoglobin. ■ Effects of severe renal impairment (CrCl less than 15 mL/min) on siltuximab pharmacokinetics have not been determined. ■ Patients with severe hepatic impairment (Child-Pugh Class C) were not included in clinical trials. ■ A protein substance, it has the potential for producing an immune response. Anti-siltuximab antibodies have been detected in a small number of patients; clinical significance unknown.

Monitor:

Obtain ANC, platelets, and hemoglobin before each dose for the first 12 months and every 3 dosing cycles thereafter. Consider delay of treatment if established parameters are not met. Do not reduce dose; see Usual Dose. ■ Monitor closely for S/S of infections. Prompt anti-infective therapy is recommended. Do not administer further siltuximab until the infection resolves. ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, chills, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, urticaria) or infusion reaction (e.g., back pain, chest pain or discomfort, erythema, flushing, palpitations, nausea and vomiting). ■ Promptly evaluate patients presenting with symptoms that may be associated or suggestive of GI perforation. ■ Monitor uric acid levels as indicated. May be treated with adequate hydration and, if necessary, with uric acid–lowering drugs (e.g., allopurinol). ■ Assess patient’s overall health at each treatment visit.

Patient Education:

Review manufacturer’s medication guide before each dose. ■ Discuss recommended vaccinations before treatment with siltuximab. ■ Promptly report S/S of serious hypersensitivity or infusion reaction during the infusion. S/S include chest tightness, difficulty breathing, severe dizziness or light-headedness, swelling of the lips, skin rash, and wheezing. ■ May lower resistance to infections; promptly report S/S of infection (e.g., fever, sore throat, unusual redness around a sore). ■ Report any S/S of new or worsening medical conditions. ■ Avoid pregnancy. Women of childbearing potential should use effective contraception during treatment and for 3 months after treatment.

Maternal/Child:

Category C: avoid pregnancy; use during pregnancy only if potential benefit justifies the risk to the fetus. ■ Use of effective contraception indicated during and for 3 months after treatment is complete. ■ Infants born to pregnant women taking siltuximab may be at an increased risk for infection. Caution is advised in the administration of live virus vaccines to these infants. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Differences in response compared with younger adults have not been identified, but greater sensitivity of older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

Inhibition of IL-6 signaling in patients treated with siltuximab may increase metabolism of CYP_{450} substrates. When initiating or discontinuing siltuximab in patients being treated with CYP_{450} substrates with a narrow therapeutic index, monitoring of effect (e.g., INR with warfarin [Coumadin]) or drug concentrations (e.g., cyclosporine [Sandimmune], theophylline) may be required. Adjust dose as needed. The effect of siltuximab on CYP_{450} enzyme activity can persist for several weeks after stopping therapy. Use caution when siltuximab is coadministered with CYP3A4 substrates when a decrease in effectiveness would be undesirable (e.g., atorvastatin [Lipitor], lovastatin [Mevacor], oral contraceptives). ■ Do not administer live virus vaccines to patients receiving siltuximab.

SIDE EFFECTS

The most commonly reported side effects were hyperuricemia, increased weight, pruritus, rash (rash generalized, rash maculopapular, rash popular, and rash pruritic), and upper respiratory tract infection. Concurrent active severe infections, gastrointestinal perforation, and hypersensitivity and/or infusion-related reactions may occur. Other side effects reported include arthralgia, constipation, diarrhea, dry skin, eczema, edema (generalized, localized), fatigue, headache, hypercholesterolemia, hypertriglyceridemia, hyperuricemia, hypotension, lower respiratory tract infection, oropharyngeal pain, pain in extremities, psoriasis, renal impairment, skin hyperpigmentation, and thrombocytopenia. Abdominal pain, dizziness, gastroesophageal reflux disease, hypertension, mouth ulceration, nasopharyngitis, nausea, neutropenia, and urinary tract infection have also been reported.

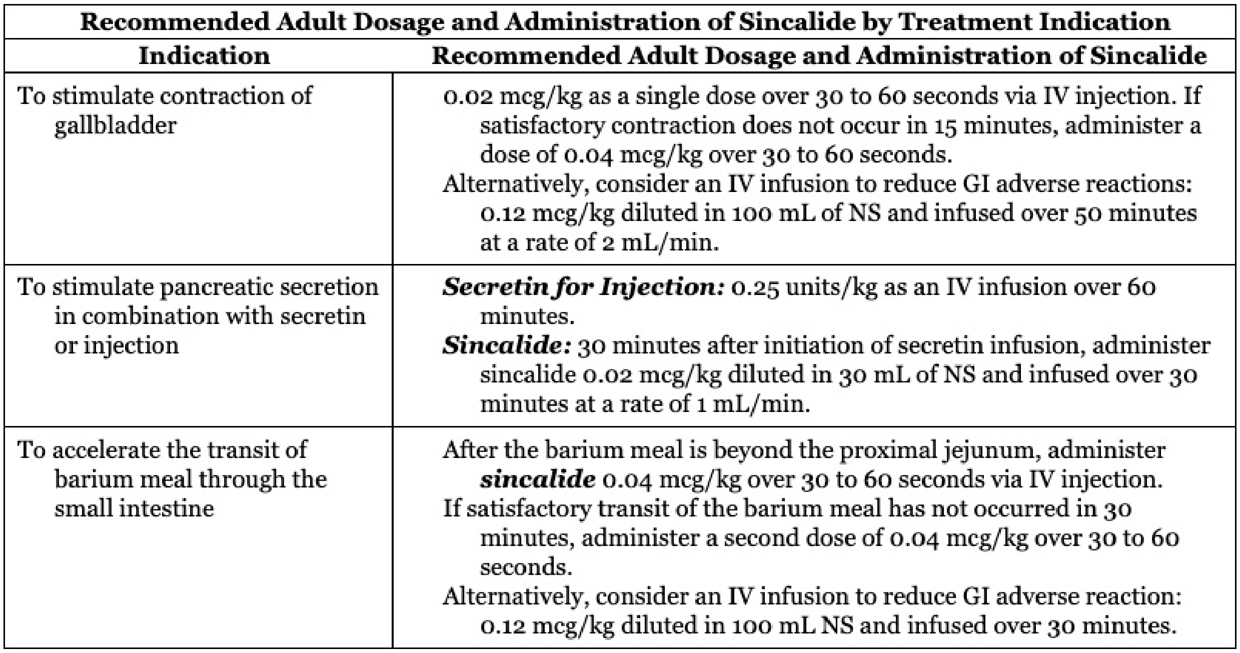
ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. Based on the severity of the reaction, slow the infusion rate, temporarily interrupt, or discontinue the infusion. Manage acute reactions that require intervention by either temporarily interrupting or discontinuing the infusion and administering antihistamines, antipyretics, or corticosteroids as necessary. Discontinue siltuximab in patients with severe hypersensitivity and/or infusion-related reactions, anaphylaxis, or cytokine release syndromes. Do not reinstitute treatment. Treat with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

SINCALIDE

(**SIN**-ka-lide)
Kinevac
Diagnostic agent
pH 6 to 8

USUAL DOSE



Recommended Adult Dosage and Administration of Sincalide by Treatment Indication	
Indication	**Recommended Adult Dosage and Administration of Sincalide**
To stimulate contraction of gallbladder	0.02 mcg/kg as a single dose over 30 to 60 seconds via IV injection. If satisfactory contraction does not occur in 15 minutes, administer a dose of 0.04 mcg/kg over 30 to 60 seconds. Alternatively, consider an IV infusion to reduce GI adverse reactions: 0.12 mcg/kg diluted in 100 mL of NS and infused over 50 minutes at a rate of 2 mL/min.
To stimulate pancreatic secretion in combination with secretin or injection	***Secretin for Injection:*** 0.25 units/kg as an IV infusion over 60 minutes. ***Sincalide:*** 30 minutes after initiation of secretin infusion, administer sincalide 0.02 mcg/kg diluted in 30 mL of NS and infused over 30 minutes at a rate of 1 mL/min.
To accelerate the transit of barium meal through the small intestine	After the barium meal is beyond the proximal jejunum, administer ***sincalide*** 0.04 mcg/kg over 30 to 60 seconds via IV injection. If satisfactory transit of the barium meal has not occurred in 30 minutes, administer a second dose of 0.04 mcg/kg over 30 to 60 seconds. Alternatively, consider an IV infusion to reduce GI adverse reaction: 0.12 mcg/kg diluted in 100 mL NS and infused over 30 minutes.

DILUTION

For IV injection:

Reconstitute each 5-mg vial of sincalide by adding 5 mL of SW for injection to the vial. Withdraw the prescribed dose of the recommended solution from the vial. For single use only; discard unused portion.

For IV infusion:

Reconstitute each 5-mg vial of sincalide by adding 5 mL of SW for injection to the vial. After reconstitution, withdraw the prescribed dose of the solution from the vial. Discard unused portion. Dilute the reconstituted solution in 30 mL or 100 mL of NS depending on the indication; see Usual Dose.

Storage:

Store vials at room temperature before dilution. Reconstituted solution may be kept at CRT for 8 hours, then discarded. Infusions in NS may be kept at RT and discarded after 1 hour.

COMPATIBILITY

Compatibility information not available from manufacturer. Consider specific use; consult a pharmacist.

RATE OF ADMINISTRATION

Too-rapid injection may increase incidence of side effects. Use of an infusion over a specified rate (see Usual Dose) may lessen intestinal side effects.

Contraction of the gallbladder:

Injection: A single dose evenly distributed over 30 to 60 seconds. ***Infusion:*** 2 mL/min.

Secretin-sincalide test of pancreatic function:

Evenly distribute secretin over 60 minutes. Evenly distribute sincalide over 30 minutes (approximately 1 mL/min).

Accelerate transit time of barium meal:

Injection: A single dose evenly distributed over 30 to 60 seconds. ***Infusion:*** 100 mL evenly distributed over 30 minutes.

ACTIONS

A cholecystopancreatic-gastrointestinal hormone peptide. Sincalide is a synthetic C-terminal octapeptide of cholecystokinin. Causes the gallbladder to contract and evacuate bile in a manner similar to endogenous cholecystokinin. Maximum effect is achieved in 5 to 15 minutes. Like cholecystokinin, sincalide stimulates pancreatic secretion and intestinal motility, causing pyloric contraction and slowing gastric emptying. When given in conjunction with secretin, both the volume of pancreatic secretion and the output of bicarbonate and enzymes are increased.

INDICATIONS AND USES

To stimulate gallbladder contraction (may be assessed by various methods of diagnostic imaging) or to obtain by duodenal aspiration a sample of concentrated bile for analysis of cholesterol, bile salts, phospholipids, and crystals. ■ To stimulate pancreatic secretion in combination with secretin prior to obtaining a duodenal aspirate for analysis of enzyme activity, composition, and cytology. ■ To accelerate the transit of a barium meal through the small bowel, decreasing time and extent of radiation associated with fluoroscopy and x-ray examination of the intestinal tract.

CONTRAINDICATIONS

Known hypersensitivity to sincalide. ■ Intestinal obstruction.

PRECAUTIONS

Serious hypersensitivity reactions, including anaphylaxis and anaphylactic shock, have been reported during and within 1 hour after administration of sincalide. Should be administered in a facility equipped to monitor the patient and respond to any medical emergency. Do not re-initiate sincalide in patients who have experienced a hypersensitivity reaction. ■ Small gallbladder stones may be evacuated from the gallbladder and become lodged in the cystic duct or common bile duct. ■ Administration as an IV injection may cause abdominal pain or cramping, dizziness, flushing, nausea, and vomiting. These reactions are generally transient; see Usual Dose.

Monitor:

Monitor for S/S of hypersensitivity reactions during and after administration. ■ Monitor V/S and observe for symptoms of pyloric contraction and/or sincalide-induced vagal stimulation.

Patient Education:

Immediately report any S/S of hypersensitivity reaction (e.g., abdominal pain, bradycardia, hives, hypotension, itching, nausea, numbness of face and lips, rash, shortness of breath, sweating, throat tightness). ■ May cause transient GI symptoms.

Maternal/Child:

Based on limited human data and mechanism of action, sincalide may cause preterm labor or spontaneous abortion. ■ No data regarding the presence of sincalide in human or animal milk, the effects on the breast-fed infant, or the effects on milk production. ■ Safety for use in pediatric patients not established.

Elderly:

Clinical studies did not include sufficient numbers of subjects 65 years of age and over to determine whether they respond differently from younger subjects.

DRUG/LAB INTERACTIONS

Drugs that may stimulate or inhibit gallbladder motility or contractile response (e.g., erythromycin) may interfere with the response to sincalide. Consider discontinuing these drugs before administration of sincalide when used to stimulate contraction of the gallbladder.

SIDE EFFECTS

Abdominal discomfort, abdominal pain, and nausea are most common. Diarrhea, dizziness, flushing, headache, hypersensitivity reactions (e.g., abdominal cramping; anaphylactic shock; anaphylaxis; bradycardia; diaphoresis; hives; hypotension; itching; nausea; numbness of face, lips, and eye; rash; shortness of breath; throat tightness), hypertension, loss of consciousness, numbness, seizures, sneezing, syncope, urge to defecate, and vomiting may occur.

Overdose:

Abdominal cramps, bradycardia, diarrhea, ECG changes, hypotension with dizziness and fainting, nausea and vomiting.

ANTIDOTE

Keep physician informed of side effects. Assist patient with comfort measures. Side effects may be lessened with a reduced injection rate. Overdose symptoms should be of short duration; treat symptomatically. Immediately discontinue sincalide at the first sign of a hypersensitivity reaction. Initiate appropriate treatment (e.g., antihistamines, epinephrine, corticosteroids) and resuscitate as necessary.

SIPULEUCEL-T

Provenge
Autologous cellular immunotherapy
Antineoplastic

USUAL DOSE

An autologous (derived from the same individual) cellular immunotherapy. Each infusion of sipuleucel-T is preceded by a leukapheresis procedure and a specific preparation procedure by the manufacturer; see Dilution and Actions. Three complete doses are administered at approximately 2-week intervals (range of 1 to 15 weeks in clinical trials).

Approximately 3 days before the desired infusion date:

Leukapheresis:

Peripheral blood mononuclear cells are obtained via a standard leukapheresis procedure. These cells are then sent to the manufacturer (Dendreon) to be prepared for re-infusion into the patient.

Day of infusion:

Premedication:

Administer oral acetaminophen and an antihistamine (e.g., diphenhydramine) 30 minutes before administration to minimize potential acute infusion reactions (e.g., chills, fever).

Sipuleucel-T:

For autologous IV use only. Do **not** use a cell filter. Confirm that the patient's identity matches the patient identifiers on the infusion bag and the Cell Product Disposition Form (CPDF). Each dose contains a minimum of 50,000,000 autologous CD54+ cells activated with PAP-GM-CSF and suspended in 250 mL of LR in a sealed, patient-specific infusion bag. Do **not** infuse until confirmation of product release has been received from Dendreon; see Dilution. Infusion must begin before the expiration date and time on the Cell Product Disposition Form (CPDF).

DILUTION

Will be shipped directly to the infusing provider in packaging intended to protect the infusion bag and maintain storage temperatures until infusion. Verify the product and patient-specific labels located on top of the insulated container. Do **not** remove from the shipping box or open the lid of the insulated container until the patient is ready for infusion. The manufacturer will send to the infusion site a CPDF that contains the patient identifiers, expiration date and time, and disposition status (approved for infusion or rejected). When all preparations have been made for infusion and the CPDF has been received and verified, remove the sipuleucel-T infusion bag from the insulated container and inspect for signs of leakage. Contents will be slightly cloudy and a cream-to-pink color. Gently mix and resuspend contents, inspecting for clumps and clots. Small clumps of cellular material should disperse with gentle manual mixing. Do **not** administer if the bag leaks during handling or if clumps remain in the bag.

Filters:

Do not use a cell filter.

Storage:

After removal from the insulated container, the infusion must be complete within 3 hours at RT. Do not return to the shipping container. Do not initiate infusion of expired sipuleucel-T.

COMPATIBILITY

Specific information not available; however, specific use indicates it should be administered separately; consult pharmacist.

RATE OF ADMINISTRATION

A single dose of 250 mL as an infusion equally distributed over 1 hour. Do **not** use a cell filter. If an infusion reaction occurs, decrease rate or interrupt infusion depending on the severity of the reaction; see Antidote.

ACTIONS

An autologous cellular immunotherapy. The patient’s own immune cells are obtained through leukapheresis. Active components of sipuleucel-T are autologous peripheral blood mononuclear cells, including antigen-presenting cells (APCs) and PAP-GM-CSF (prostatic acid phosphatase [PAP], an antigen expressed in prostate cancer tissue, linked to granulocyte-macrophage colony-stimulating factor [GM-CSF], an immune cell activator). The recombinant antigen can bind to and be processed by APCs into smaller protein fragments. The recombinant antigen is designed to target APCs and may help direct the immune response to PAP. The final product contains T-cells, B-cells, natural killer (NK) cells, and other cells.

INDICATIONS AND USES

Treatment of asymptomatic or minimally symptomatic metastatic hormone refractory prostate cancer.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Intended solely for autologous use. For IV use only. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Concurrent use of immunosuppressive agents may alter the effectiveness and/or safety of sipuleucel-T; see Drug/Lab Interactions. ■ Health care professionals must use universal precautions when handling leukapheresis material and sipuleucel-T. Neither is routinely tested for transmissible infectious diseases and thus may carry the risk of infectious disease transmission to health professionals during handling of the products. ■ Acute infusion reactions (reported within 1 day of infusion) occur frequently and range from mild to serious; see Monitor. Incidence increased with the second infusion and decreased after the third infusion.

Monitor:

Obtain baseline vital signs and repeat as indicated. ■ Observe the patient for S/S of an acute infusion reaction (e.g., bronchospasm, chills, fatigue, fever, hypertension, joint aches, nausea, tachycardia) during the infusion and for at least 30 minutes after the infusion. If an acute infusion reaction occurs, the infusion may be interrupted or slowed depending on the severity of the reaction. Do not resume the infusion if the bag will be held at RT for more than 3 hours. ■ Closely monitor patients with cardiac or pulmonary conditions. ■ If the patient is unable to receive a scheduled infusion, the patient will need to undergo an additional leukapheresis procedure. ■ Monitor for extravasation.

Patient Education:

Maintain all scheduled appointments. ■ An additional leukapheresis procedure will be required if a scheduled infusion cannot be completed. ■ A central venous line may be required if peripheral venous access is not adequate to accommodate the leukapheresis procedure and/or the infusion. ■ Promptly report S/S of an infusion reaction (e.g., breathing problems, chills, dizziness, fatigue, fever, headache, hypertension, muscle aches, nausea, or vomiting). ■ Report S/S that may indicate a cardiac arrhythmia (e.g., very slow or rapid pulse). ■ Review prescription and nonprescription drug profile with a physician; see Drug/Lab Interactions.

Maternal/Child:

Not indicated for use in these populations.

Elderly:

Safety similar to that seen in younger adults.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been performed. ■ Use of either **chemotherapy or immunosuppressive agents** (such as systemic corticosteroids) given concurrently with the leukapheresis procedure or sipuleucel-T has not been studied. ■ Sipuleucel-T is designed to stimulate the immune system, and concurrent use of **immunosuppressive agents** may alter the effectiveness and/or safety of sipuleucel-T. Evaluate patients carefully for the medical appropriateness of reducing or discontinuing immunosuppressive agents before treatment.

SIDE EFFECTS

The most common events of backache, chills, fatigue, fever, headache, joint aches, and nausea are usually mild or moderate and generally resolve within 2 days. Other side effects included anemia, anorexia, citrate toxicity, constipation, cough, diarrhea, hematuria, hot flush, influenza-like illness, insomnia, muscle aches and spasms, pain (back, bone, chest [musculoskeletal], extremity, and neck), paresthesia (oral, extremity), peripheral edema, rash, sweating, tremor, URIs, UTIs, weight loss. Acute infusion reactions (mild to moderate) occur frequently. Severe acute infusion reactions (Grade 3) add asthenia, bronchospasm, dizziness, dyspnea, hypertension, hypoxia, and vomiting. Cerebrovascular events (e.g., hemorrhagic and ischemic strokes) and single reports of eosinophilia, myasthenia gravis, myositis, rhabdomyolysis, and tumor flare have been reported.

ANTIDOTE

Keep the physician informed of significant side effects and treat as appropriate. For acute infusion reactions, the infusion may be interrupted or slowed depending on the severity of the reaction. Do not resume the infusion if the bag will be held at RT for more than 3 hours. In controlled clinical trials, acute infusion reactions were treated with acetaminophen, IV antihistamines (e.g., diphenhydramine) and/or H_2 blockers, and low-dose IV meperidine. Resuscitate as indicated.

SODIUM ACETATE

(**SO**-dee-um **AS**-ah-tayt)
Electrolyte replenisher
Antihyponatremic
Alkalizing agent
pH 6 to 7

USUAL DOSE

Determined by nutritional needs, evaluation of electrolytes, and degree of hyponatremia. Some solutions may contain aluminum; see Precautions. Available in 2 mEq and 4 mEq/mL concentrations. Each mL provides 2 or 4 mEq each of sodium and acetate.

DOSE ADJUSTMENTS

Lower-end initial doses may be appropriate in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Must be added to larger volumes of IV infusion solutions including total parenteral nutrition. Use only clear solutions. Check labels for aluminum content; see Precautions.

Storage:

Store at room temperature. Discard unused portion.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer at prescribed rate for infusion solutions. Rapid or excessive administration may produce sodium overload, water retention, alkalosis, or hypokalemia.

ACTIONS

An alkalizing agent and sodium salt. Sodium is the predominant cation of extracellular fluid. It controls water distribution throughout the body. Hypothalamus osmoreceptors, sensitive to osmolarity changes in the blood, control serum sodium concentration (142 mEq/L). Body fluid is lost when sodium content decreases and retained when sodium content increases. Sodium is excreted by the kidney. The acetate ion is metabolized to bicarbonate, thus providing a source of bicarbonate. It also acts as a hydrogen ion receptor.

INDICATIONS AND USES

To prevent or correct hyponatremia in patients with restricted intake, especially in individualized IV formulations when basic needs are not met by standard solutions. ■ Treatment of mild to moderate acidotic states. ■ Source of sodium ions in hemodialysis and peritoneal dialysis.

CONTRAINDICATIONS

Patients with hypernatremia or water retention.

PRECAUTIONS

Use with caution in impaired renal function, congestive heart failure, hypertension, peripheral or pulmonary edema, any condition resulting in salt retention, and in patients receiving corticosteroids. ■ Use acetate-containing solutions with extreme caution in patients with metabolic or respiratory alkalosis and/or impaired hepatic function. ■ Temporary therapy in acidosis. Treatment of primary condition must be instituted. ■ Sodium bicarbonate is the drug of choice for use in severe acidosis that requires immediate correction. ■ Some solutions of sodium acetate contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation.

Monitor:

Evaluate electrolytes frequently during treatment. ■ Evaluate fluid balance. ■ Rapid or excessive administration may produce alkalosis or hypokalemia. Cardiac arrhythmias may result from an intracellular shift of potassium. Many other complications may arise from electrolyte imbalance.

Maternal/Child:

Category C: safety not established; use only if clearly needed.

Elderly:

Differences in response between elderly and younger patients have not been identified. Lower-end initial doses may be appropriate in the elderly; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Alkalinization of urine may increase the renal elimination and decrease the effects of many drugs, including **tetracyclines, lithium, methotrexate, and salicylates,** and may decrease the renal elimination and prolong the effects of others, including **anorexiants, flecainide, mecamylamine, quinidine, and sympathomimetics**.

SIDE EFFECTS

Hypernatremia, sodium level over 147 mEq/L, is most common (congestive heart failure, delirium, dizziness, edema, fever, flushing, headache, hypotension, oliguria, pulmonary edema, reduced salivation and lacrimation, respiratory arrest, restlessness, swollen tongue, tachycardia, thirst, weakness). Alkalosis and fluid or solute overload can occur.

ANTIDOTE

Notify the physician of any side effect. Reduce rate and notify physician at first sign of congestion or fluid overload. May be treated by sodium restriction and/or use of diuretics or dialysis. Resuscitate as necessary.

SODIUM BICARBONATE

(**SO**-dee-um bye-**KAR**-bon-ayt)
Electrolyte replenisher
Alkalizing agent
pH 7 to 8.5

USUAL DOSE

Adjusted according to pH, Pa_{CO_2}, calculated base deficit, clinical response, and fluid limitations of the patient. In the presence of a low CO_2 content, adjust gradually to avoid unrecognized alkalosis. Correction to a CO_2 of 20 mEq/L within 24 hours will most likely result in a normal pH if the cause of acidosis is controlled and normal kidney function is present. Average dose for most indications is 2 to 5 mEq/kg/24 hr in adults and pediatric patients.

Cardiac arrest:

1 mEq/kg of body weight, only when appropriate (see Precautions; evidence supports little benefit and use may be detrimental). Repeat half dose in 10 minutes if indicated by blood pH and Pa_{CO_2}.

PEDIATRIC DOSE

0.5 to 1 mEq/kg. For neonates and children up to 2 years of age, dose must never exceed 8 mEq/kg/24 hr of a 4.2% or more dilute solution; see Usual Dose, Monitor, and Maternal/Child.

DILUTION

4.2% sodium bicarbonate solution:

5 mEq/10 mL (0.5 mEq/mL).

5% sodium bicarbonate solution:

297.5 mEq/500 mL (0.595 mEq/mL).

7.5% sodium bicarbonate solution:

44.6 mEq/50 mL (0.892 mEq/mL).

8.4% sodium bicarbonate solution:

50 mEq/50 mL (1 mEq/mL).

neut (4% sodium bicarbonate solution):

2.4 mEq/5 mL (0.48 mEq/mL). Use limited to a buffering solution. Will raise pH of IV fluids and medications. Never used as a systemic alkalinizer.

May be given in prepared solutions. 7.5% and 8.4% solutions should be diluted with equal amount of water for injection, or diluted with **compatible** IV solutions, depending on desired dosage and desired rate of administration. 4.2% or a more dilute solution is preferred for infants and children. Use only clear solutions. Dilution should be in D5W or sterile water for injection (done by pharmacy) due to the sodium content of sodium bicarbonate.

COMPATIBILITY

Will form a precipitate with many drugs, including epinephrine. ***If coadministration with epinephrine is indicated, give at separate sites.***

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Flush IV line thoroughly before and after administration. Usual rate of administration of any solution is 2 to 5 mEq/kg over 4 to 8 hours. Do not exceed 50 mEq/hr. Decrease rate for pediatric patients. See Pediatric Dose. Rapid or excessive administration may produce alkalosis, hypernatremia, hypocalcemia, and hypokalemia. Cardiac arrhythmias may result from an intracellular shift of potassium. Will also produce pain and irritation along injection site.

Cardiac arrest:

Up to 1 mEq/kg properly diluted over 1 to 3 minutes.

ACTIONS

An alkalizing agent and sodium salt. Helps to maintain osmotic pressure and ion balance. It is the buffering agent in blood. Bicarbonate ion elevates blood pH promptly. 99% reabsorbed with normal kidney function. Only 1% is excreted in the urine.

INDICATIONS AND USES

Metabolic acidosis (blood pH below 7.2 or plasma bicarbonate of 8 mEq/L or less) caused by circulatory insufficiency resulting from shock or severe dehydration, extracorporeal circulation of blood, severe renal disease, cardiac arrest (see Precautions), uncontrolled diabetes with ketoacidosis (low-dose insulin preferred), and primary lactic acidosis. ■ Hyperkalemia. ■ Hemolytic reactions requiring alkalinization of urine to reduce nephrotoxicity. ■ Severe diarrhea. ■ Barbiturate, methyl alcohol, or salicylate intoxication. ■ Buffering solution to raise pH of IV fluids and medications.

CONTRAINDICATIONS

Diuretics known to produce hypochloremic alkalosis (e.g., thiazides), edema, hypertension, hypocalcemia (alkalosis may produce CHF, convulsions, hypertension, and tetany), hypochloremia (from vomiting, GI suction, or diuretics), hypernatremia, impaired renal function, metabolic alkalosis, respiratory alkalosis or acidosis, and any situation in which the administration of sodium could be clinically detrimental.

PRECAUTIONS

Temporary therapy in metabolic acidosis. Treatment of primary condition must be instituted. Best to partially correct acidosis and allow compensatory mechanisms to complete the correction. ■ Use with caution in cardiac, liver, or renal disease; CHF; fluid/solute overload; elderly and postoperative patients with renal or cardiovascular insufficiency; and in patients receiving corticosteroids. ■ Use in cardiac arrest indicated only in cases of prolonged resuscitation with effective ventilation or after return of spontaneous circulation after a long arrest interval. ■ Adequate alveolar ventilation should control acid-base balance in most arrest situations except prolonged cardiac arrest, arrested patients with pre-existing metabolic acidosis, hyperkalemia, or tricyclic or barbiturate overdose.

Monitor:

Confirm absolute patency of vein. Extravasation may cause chemical cellulitis, necrosis, ulceration, or sloughing. ■ Flush IV line thoroughly before and after administration; many **incompatibilities**. ■ Rapid or excessive administration may produce alkalosis, hypokalemia, and hypocalcemia. Cardiac arrhythmias may result from an intracellular shift of potassium. Many other complications may arise from electrolyte imbalance. ■ Use only 50-mL ampules in cardiac arrest to prevent accidental overdose. Recent practice indicates smaller doses may be appropriate when indicated in cardiac arrest and may prevent secondary alkalosis. Adequate alveolar ventilation is imperative. Evaluate patient response and blood gases.

Maternal/Child:

Category C: safety for use in pregnancy not established; use only if clearly needed. ■ Use caution in breast-feeding. ■ Doses in excess of 8 mEq/kg/24 hr and/or given too rapidly (10 mL/min) may cause intracranial hemorrhage, hypernatremia, and decrease in cerebrospinal fluid pressure in neonates and children under 2 years.

Elderly:

Contains sodium; use caution in the elderly with renal or cardiovascular insufficiency with or without CHF; see Precautions.

DRUG/LAB INTERACTIONS

Alkalinization of urine may increase the renal elimination and decrease the effects of many drugs, including **tetracyclines, chlorpropamide, lithium carbonate, methotrexate, salicylates,** and may decrease the renal elimination and prolong the effects of others, including **anorexiants** (e.g., amphetamines), **flecainide, mecamylamine, quinidine, sympathomimetics** (e.g., dopamine, ephedrine).

SIDE EFFECTS

Rare when used with caution: alkalosis (hyperirritability and tetany), hypernatremia (edema, CHF), hypokalemia, local site venous irritation.

ANTIDOTE

Discontinue the drug and notify the physician of any side effect. Hypokalemia usually occurs with alkalosis. Sodium and potassium chloride must be supplemented as indicated for correction. Treatment of alkalosis often results in more alkalosis. Rebreathing expired air from a paper bag may help to control beginning symptoms of alkalosis. Calcium gluconate may help in severe alkalosis. Administration of a balanced hypotonic electrolyte solution (Isolyte H, Normosol-M, Plasma-lyte 56) with sodium and potassium chloride added may help to excrete the bicarbonate ion in the urine. Ammonium chloride may be indicated. Treat tetany as indicated (calcium gluconate). For extravasation, discontinue infusion; aspirate fluid, drug, and/or 3 to 5 mL of blood through the in-place needle, then remove the needle. Elevate the extremity and apply warm, moist compresses. Resuscitate as necessary.

SODIUM CHLORIDE

(**SO**-dee-um **KLOR**-eyed)
Electrolyte replenisher
Antihyponatremic
pH 4.5 to 7

USUAL DOSE

Highly individualized and dependent on age, weight, clinical condition of patient, concentration of salts in the plasma, and/or loss of body fluids.

Hypotonic:

(0.45% [½NS], 4.5 Gm of sodium chloride/L or 77 mEq of sodium and 77 mEq of chloride [approximately 155 mOsm/L]) 2 to 4 L/24 hr.

Isotonic:

(0.9% [NS], 9 Gm of sodium chloride/L or 154 mEq of sodium and 154 mEq of chloride [approximately 310 mOsm/L]) 1.5 to 3 L/24 hr.

Bacteriostatic isotonic NS contains benzyl alcohol as a preservative. It is used in small amounts (usually 1 to 2 mL) as a diluent for injectable drugs (IV, IM, SC) or to flush IV lines. One study suggests that up to 30 mL/dose may be used in adults. However, the amount of benzyl alcohol that is tolerated within 24 hours in adults without toxic effects has not been determined. ***Use only preservative-free sodium chloride in newborns for all indications.***

Hypertonic:

Calculate sodium deficit. Total body water (TBW) is 45% to 50% in females and 50% to 60% in males.

$$\text{Na deficit in mEq} = \text{TBW}\ [\text{desired} - \text{observed plasma Na}]$$

Hypertonic (3%, 30 Gm of sodium chloride/L or 513 mEq of sodium and 513 mEq of chloride [approximately 1,030 mOsm/L] or 5%, 50 Gm of sodium chloride/L or 855 mEq of sodium and 855 mEq of chloride [approximately 1,710 mOsm/L]), 200 to 400 mL/24 hr. To correct ***acute serious hyponatremia,*** hypertonic sodium chloride is used to correct the serum sodium in 5 mEq/L/dose increments at a rate of no more than 0.5 mEq/hr until serum sodium is 125 mEq/L or neurologic symptoms improve. In the first 3 to 4 hours, an increase of plasma sodium at rates up to 1 mEq/L/hr may be tolerated in patients with distressing symptoms. To prevent an overly rapid correction, an increase in plasma sodium of less than 10 mEq/L in the first 24 hours and an increase of less than 18 mEq/L in the first 48 hours is desired. See Precautions.

Concentrated:

To be used only as an additive in parenteral fluid therapy (14.6% contains 2.5 mEq of sodium and chloride/mL; 23.4% contains 4 mEq of sodium and chloride/mL).

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly, especially with hypertonic or concentrated solutions. Start at the lower end of the desired dosing range; consider the greater frequency of decreased organ function and of concomitant disease or drug therapy.

DILUTION

Available as ***hypotonic*** 25 mL, 50 mL, 150 mL, 250 mL, 500 mL, 1 L; ***isotonic*** (2 mL, 3 mL, 5 mL, 10 mL, 20 mL, 25 mL, 30 mL, 50 mL, 100 mL, 150 mL, 250 mL, 500 mL, 1 L); or ***hypertonic*** (500 mL) solution in vials and/or bottles for injection or infusion and ready for use. Isotonic and hypotonic sodium chloride are frequently combined with 5% or 10% dextrose. ***Concentrated*** must be diluted before use. Used only as an additive in parenteral fluids. Permits specific mEq for mEq replacement of sodium and chloride without contributing to fluid overload. Available in 14.6% strength in 20 mL, 40 mL, and 200 mL; 23.4% strength in 30 mL, 50 mL, 100 mL, and 200 mL.

Bacteriostatic isotonic available in 2-mL, 10-mL, and 30-mL vials ready for use as a diluent. Never use in neonates.

Storage:

Store at CRT. Do not freeze.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV infusions in flexible plastic containers:

Do not hang in series connection, do not pressurize to increase flow rates without first fully evacuating residual air from the container, and do not use vented IV administration sets. All may result in air embolism.

Isotonic and hypotonic:

A single daily dose equally distributed over 24 hours. Rate is dependent on age, weight, and clinical condition of the patient.

Hypertonic:

One-half the calculated dose over at least 8 hours. Do not exceed 100 mL over 1 hour. Too-rapid infusion may cause local pain and venous irritation; reduce rate for tolerance; see Usual Dose.

Concentrated:

Properly diluted in parenteral fluids and equally distributed over 24 hours. Never exceed hypertonic rate (see above) based on actual mEq of sodium chloride.

ACTIONS

Sodium:

The predominant cation of extracellular fluid. It controls water distribution throughout the body. Hypothalamus osmoreceptors, sensitive to osmolarity changes in the blood, control serum sodium concentration (142 mEq/L). Body fluid is lost when sodium content decreases and retained when sodium content increases.

Chloride:

The major extracellular anion. Closely follows the metabolism of sodium. Changes in the acid-base balance of the body are reflected by the changes in chloride concentration.

Distribution and excretion of sodium and chloride are largely under control of the kidney, which maintains a balance between intake and output.

INDICATIONS AND USES

Replace lost fluid or sodium and chloride ions in the body (e.g., hyponatremia, low salt syndrome, dehydration). ■ Maintain fluid and electrolyte balance.

Hypotonic:

Water replacement without increase of osmotic pressure or serum sodium levels; treatment of hyperosmolar diabetes requiring considerable fluid without excess sodium.

Isotonic:

To replace sodium and chloride lost from vomiting because of obstructions and/or aspiration of GI fluids; treatment of metabolic alkalosis with fluid loss and sodium depletion. ■ Diluent in parenteral preparations. ■ To initiate and terminate blood transfusions without hemolyzing RBCs. ■ Maintain patency and perform routine irrigations of many types of intravascular devices (e.g., catheters, implanted ports). ■ Antidote for drug-induced hypercalcemia. Given concurrently with furosemide (Lasix). ■ Priming solution in hemodialysis procedures.

Hypertonic:

Used only when high sodium and/or chloride content without large amounts of fluid is required (e.g., electrolyte and fluid loss replaced with sodium-free fluids, excessive water intake resulting in drastic dilution of body water, emergency treatment of severe salt depletion, Addisonian crisis, diabetic coma).

Concentrated:

Used to meet the specific requirements of patients with unusual fluid and electrolyte needs (e.g., special problems of sodium electrolyte intake or excretion).

CONTRAINDICATIONS

Hypernatremia; fluid retention; situations in which sodium or chloride could be detrimental. 3% and 5% sodium chloride solutions are contraindicated with elevated, normal, or slightly decreased serum sodium and chloride levels. Bacteriostatic sodium chloride is contraindicated in newborns.

PRECAUTIONS

Use caution in circulatory insufficiency, congestive heart failure, edema with sodium retention, kidney dysfunction, hepatic disease, hypoproteinemia, in the elderly or debilitated individuals, and in patients receiving corticosteroids. ■ Use with caution in surgical patients; see Monitor. ■ More than 1 liter of NS may cause hypernatremia, which can result in loss of bicarbonate ions and acidosis. ■ All uses require preservative-free solutions except the limited use of bacteriostatic NS as a diluent or flushing agent. ■ Inadvertent direct injection or absorption of concentrated sodium chloride may cause sudden hypernatremia, cardiovascular shock, CNS disorders, extensive hemolysis, cortical necrosis of the kidneys, and severe local tissue necrosis with extravasation. Use extreme caution; see Dilution. ■ Administration of IV solutions can cause fluid and/or solute overload, resulting in dilution of serum electrolyte concentrations, overhydration, congested states, or pulmonary edema. The risk of dilutional states is inversely proportional to the electrolyte concentration (increased fluids may dilute electrolyte concentration). The risk of solute overload causing congested states with peripheral and pulmonary edema is directly proportional to the electrolyte concentration (higher electrolytes pull in fluid, leading to fluid overload). ■ Overly rapid correction of severe hyponatremia (plasma sodium less than 110 to 115 mEq/L) may lead to a neurologic disorder (osmotic demyelination syndrome [central pontine myelinolysis]), which may be irreversible; see Usual Dose.

Monitor:

Maintain accurate intake and output; monitor electrolytes and acid-base balance, especially in prolonged therapy. ■ Monitor vital signs as indicated. ■ Monitor for signs of hyponatremia (sodium less than 135 mEq/L [e.g., disorientation, headache, lethargy, nausea, weakness]). May progress to coma and seizures. ■ Excessive administration of potassium-free solutions may cause hypokalemia. ■ Before and during use of hypertonic or concentrated sodium chloride, determine osmolar concentrations and chloride and bicarbonate content of the serum. Observe patient continuously to prevent pulmonary edema. ■ Hypertonic solutions can cause vein damage; use a small needle and a large vein to reduce venous irritation and avoid extravasation; see Precautions.

Maternal/Child:

Category C: safety for use during pregnancy not established; use only if clearly needed. ■ Use caution in breast-feeding. ■ Benzyl alcohol preservative in bacteriostatic sodium chloride has caused toxicity in newborns. Do not use. ■ Is used in pediatric patients. Safety and effectiveness based on similarity of clinical conditions of pediatric and adult populations. Use caution in neonates or very small infants; the volume of fluid may affect fluid and electrolyte balance.

Elderly:

Lower-end initial doses may be indicated in the elderly; see Dose Adjustments. ■ Incidence of adverse reactions may be increased; monitor carefully, especially with renal or cardiac insufficiency with or without CHF. ■ See Precautions.

DRUG/LAB INTERACTIONS

High sodium intake may reduce serum **lithium** concentrations.

SIDE EFFECTS

Fever, hypovolemia, and injection site reactions may occur.

Osmotic demyelination syndrome (central pontine myelinolysis) secondary to too-rapid correction with hypertonic solutions.

Due to sodium excess:

Aggravation of existing acidosis, anorexia, cellular dehydration, deep respiration, disorientation, distension, edema, hydrogen loss, hyperchloremic acidosis, hypertension, increased BUN, nausea, oliguria, potassium loss, pulmonary edema, water retention, weakness. Excessive excretion of crystalloids to maintain normal osmotic pressure will increase excretion of potassium and bicarbonate and further increase acidosis. Other salts (e.g., iodide and bromide) used for therapy will also be excreted rapidly.

ANTIDOTE

Discontinue or decrease rate of infusion; notify the physician of side effects. Sodium excess can be treated by sodium restriction and/or use of diuretics or hemodialysis to remove excessive amounts. Observe patient carefully and treat symptomatically. Save balance of fluid for examination.

SODIUM FERRIC GLUCONATE COMPLEX

(**SO**-dee-um **FAIR**-ick **GLUE**-koh-nayt **KOM**-pleks)
Ferrlecit
Antianemic Iron supplement
pH 7.7 to 9.7

USUAL DOSE

Dose is represented in terms of mg of elemental iron. Given as an infusion and may be administered during the dialysis session.

Treatment of iron deficiency in hemodialysis patients:

125 mg (10 mL)/dose. Doses above 125 mg may be associated with a higher incidence and/or severity of adverse events; see Side Effects. A minimum cumulative dose of 1 Gm of elemental iron is required by most patients. May be administered over eight sessions at sequential dialysis treatments to achieve a favorable hemoglobin or hematocrit response. Additional doses as necessary are indicated to maintain target levels of hemoglobin, hematocrit, and laboratory parameters of iron storage within acceptable limits. Use the lowest dose that achieves this goal.

PEDIATRIC DOSE

1.5 mg/kg (0.12 mL/kg) of elemental iron as a 1-hour infusion. Do not exceed 125-mg dose. Administer at 8 sequential dialysis sessions. See Maternal/Child.

DOSE ADJUSTMENTS

Begin at the low end of the dosing range in elderly patients. Consider decreased cardiac, hepatic, or renal function, and concomitant disease or other drug therapy.

DILUTION

Available in ampules or vials containing 62.5 mg/5 mL (12.5 mg/mL) of elemental iron.

Therapeutic dose:

125-mg (10-mL) dose may be diluted in 100 mL NS or may be given undiluted; see Rate of Administration.

Pediatric therapeutic dose:

Dilute calculated dose in 25 mL of NS.

Filters:

Specific studies not available from manufacturer. Filter needle not required by FDA for drug approval; however, use of a filter needle to withdraw it from an ampule should not have an adverse effect.

Storage:

Store ampules at CRT. Do not freeze. Use immediately after dilution in NS.

COMPATIBILITY

Manufacturer states, “Do not mix with other medications or add to parenteral nutrition solutions.” Known to be **compatible** only with NS.

RATE OF ADMINISTRATION

Too-rapid administration may cause hypotension associated with fatigue; lightheadedness; malaise; severe pain in the chest, back, flanks, or groin; and weakness.

Therapeutic dose:

Injection (adults only):

A single dose (undiluted) as a slow IV injection. May be given at a rate up to 12.5 mg/min (1 mL/min).

Infusion (adults and pediatric patients):

A single dose as an infusion properly diluted and equally distributed over 60 minutes.

ACTIONS

A stable macromolecular complex in sucrose injection. Contains elemental iron as the sodium salt of a ferric ion carbohydrate complex. Used to replete the total body content of iron. Iron is critical for normal hemoglobin synthesis to maintain oxygen transport and necessary for metabolism and synthesis of DNA and various other processes. Half-life is approximately 1 hour. Doses of 1 mg/day are adequate to replenish losses in healthy non-menstruating adults. Iron complex is not dialyzable.

INDICATIONS AND USES

Treatment of iron-deficiency anemia in adult patients and pediatric patients 6 years of age or older with chronic kidney disease who are receiving hemodialysis and supplemental erythropoietin therapy; see Maternal/Child.

CONTRAINDICATIONS

All anemias not associated with iron deficiency. Hypersensitivity to sodium ferric gluconate complex or any of its components.

PRECAUTIONS

Use only when truly indicated to avoid excess storage of iron. Not recommended for use in patients with iron overload. ■ Too-rapid administration may cause clinically significant hypotension; see Rate of Administration and Side Effects. ■ Studies have included patients who have had prior iron dextran exposure with hypersensitivity reactions to at least one form of iron dextran. The majority of these patients tolerated Ferrlecit therapy without a subsequent hypersensitivity reaction. ■ There have been rare occurrences of severe hypersensitivity reactions, including anaphylactic-type reactions, some of which have been life threatening and fatal. Administer in a facility equipped to monitor the patient and respond to any medical emergency. ■ Serum iron levels greater than 300 mcg/dL combined with transferrin oversaturation may indicate iron poisoning; see Side Effects.

Monitor:

Recumbent position during and after injection may help to prevent postural hypotension. Hypotensive effects may be additive to transient hypotension during dialysis and/or from too-rapid rate of infusion; monitor closely. Hypotensive reactions associated with fatigue; light-headedness; malaise; severe pain in the back, chest, flanks, or groin; and weakness may occur with IV iron. These symptoms may or may not be indicative of a hypersensitivity reaction and usually resolve within 1 or 2 hours. ■ Observe continuously for a hypersensitivity reaction during an infusion and after administration for at least 30 minutes and until clinically stable. Monitor vital signs. ■ Periodic monitoring of hemoglobin and hematocrit and iron storage levels recommended. Doses in excess of iron needs may lead to accumulation of iron in iron storage sites and iatrogenic hemosiderosis.

Patient Education:

Report S/S of a hypersensitivity reaction (e.g., difficulty breathing, rash, shortness of breath) promptly. Report pain at injection site.

Maternal/Child:

Category B: use during pregnancy only if potential benefit justifies potential risk to fetus. ■ Safety for use during breast-feeding and in pediatric patients under 6 years of age not established. ■ Contains benzyl alcohol; should not be used in neonates. Benzyl alcohol present in maternal serum may cross into human milk and may be orally absorbed by a breast-feeding infant.

Elderly:

No age differences identified. Caution in the elderly suggested; see Dose Adjustments.

DRUG/LAB INTERACTIONS

May reduce absorption of concomitantly administered **oral iron preparations.** ■ Concurrent administration of iron therapy with **dimercaprol** will result in the formation of a toxic complex. Either postpone iron therapy to at least 24 hours after dimercaprol or consider transfusions.

SIDE EFFECTS

Hypotension associated with fatigue; light-headedness; malaise; severe pain in the chest, back, flanks, or groin; and weakness may be caused by too-rapid infusion. Severe hypersensitivity reactions (e.g., angioedema, bronchospasm, cardiac arrest, cardiovascular collapse, dyspnea, edema [oral or pharyngeal], muscle spasm, pain [back or chest], pruritus, urticaria) have been reported rarely. The most commonly reported side effects include abdominal pain, back pain, chest pain, cramps, diarrhea, dizziness, dyspnea, fever, headache, hypersensitivity reactions, hypertension, hypotension, infection, injection site reactions, nausea and vomiting, pain, pharyngitis, pruritus, rhinitis, tachycardia, and thrombosis. Many other side effects occurred in less than 1% of patients and may or may not be attributable to sodium ferric gluconate complex.

Post-Marketing:

Anaphylaxis, convulsions, dysgeusia, hypoesthesia, loss of consciousness, pallor, phlebitis, shock, and skin discoloration have been identified. In addition, post-marketing reports have identified that individual doses exceeding 125 mg may result in a higher incidence and/or severity of side effects, including abdominal pain, chest pain, diarrhea, dizziness, dyspnea, hypotension, nausea, paresthesia, peripheral swelling, and urticaria.

Overdose:

Serum iron levels greater than 300 mcg/dL may indicate iron poisoning. May result in hemosiderosis, and excess iron may increase susceptibility to infection. If acute toxicity is seen, it may present as abdominal pain, diarrhea, or vomiting progressing to pallor or cyanosis, lassitude, drowsiness, hyperventilation due to acidosis, iatrogenic hemosiderosis, and cardiovascular collapse.

ANTIDOTE

Reduce rate or temporarily discontinue infusion for hypotension; volume expanders (e.g., albumin, hetastarch) may be indicated. Restart when resolved. Discontinue drug and treat hypersensitivity reactions or resuscitate as necessary; notify physician. Epinephrine and diphenhydramine should always be available. In overdose, monitor CBC, iron studies, vital signs, blood gases, and glucose and electrolytes. Maintain fluid and electrolyte balance. Correct acidosis with sodium bicarbonate. Iron complex is not dialyzable.

SODIUM THIOSULFATE

(**SOW**-dee-um thye-oh-**SUL**-fate)
Pedmark
Antidote

USUAL DOSE

Weight less than 5 kg = 10 Gm/m^2; weight 5–10 kg = 15 Gm/m^2; weight greater than 10 kg = 20 Gm/m^2

PEDIATRIC DOSE

See above.

DOSE ADJUSTMENTS

Renal:

No dosage adjustments are provided by the manufacturer.

Hepatic:

No dosage adjustments are provided by the manufacturer.

DILUTION

Calculate the dose (grams) and determine number of vials needed. Withdraw the calculated dose from the vial into the syringe or empty infusion bag. *Note:* Pedmark comes as 12.5-Gm/100 mL single-dose vial.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than normal saline.

RATE OF ADMINISTRATION

Administer as IV infusion over 15 minutes following cisplatin infusions.

ACTIONS

Sodium thiosulfate interacts directly with cisplatin to produce an inactive platinum species to help prevent ototoxicity.

INDICATIONS AND USES

Cyanide poisoning (alternative agent); to reduce ototoxicity associated with cisplatin in pediatric patients greater than 1 month of age

CONTRAINDICATIONS

History of severe hypersensitivity to sodium thiosulfate or any components

PRECAUTIONS

Hypersensitivity:

Immediately discontinue infusion with any signs of allergic reaction and institute appropriate care.

Hypernatremia and hypokalemia:

Monitor serum sodium and potassium levels at baseline and as clinically indicated. Withhold infusion if serum sodium is greater than 145 mmol/L.

Nausea and vomiting:

Administer antiemetics prior to each infusion.

Monitor:

Hypersensitivity/anaphylaxis during and after the infusion; sodium and potassium at baseline and as clinically indicated; nausea and vomiting. See package insert for dosage modifications based on adverse reactions.

Patient education:

Notify provider of or any signs of allergic reaction or nausea.

Maternal/child:

No information is available, as it is indicated only for pediatric patients. Refer to cisplatin monograph for information.

Elderly:

No specific recommendations; refer to adult dosing.

DRUG/LAB INTERACTIONS

None is listed by the manufacturer.

SIDE EFFECTS

Hypersensitivity, nausea and vomiting, hypernatremia, and hypokalemia

ANTIDOTE

There is no antidote; stop infusion for hypersensitivity reactions and treat appropriately.

SODIUM LACTATE

(**SO**-dee-um **LAK**-tayt)
Electrolyte replenisher
Alkalizing agent
pH 6 to 7.3

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Determined by severity of acidosis and based on evaluation of pH, $Paco_2$, electrolyte requirements, age, weight, clinical response, and fluid limitations of the patient. Oxidative processes must be intact (the ability of the liver to convert sodium lactate to bicarbonate and glycogen). The following formula has been used as a guide to dosing:

$$\text{Dose in mL of 1/6 M sodium lactate} = (60 - \text{Plasma } CO_2) \times (0.8 \times \text{Body weight in pounds})$$

Available as:

1/6 M sodium lactate: 500 and 1,000 mL (167 mEq each of sodium and lactate ions)

Sodium lactate:

50 mEq in 10-mL vial (5 mEq/mL each of sodium and lactate ions). Also a component in lactated Ringer's injection.

Filters:

No significant loss of drug potency noted with filtration through a 0.22-micron cellulose ester membrane filter.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established. Use has been limited; dose, dilution, and rate recommendations are not available.

DOSE ADJUSTMENTS

Caution and lower-end dosing suggested in elderly patients. Consider age-related impaired organ function and concomitant disease or drug therapy.

DILUTION

1/6 M sodium lactate:

Prediluted and ready for use.

Sodium lactate (50 mEq/10 mL [5 mEq/mL]):

Must be added to larger volumes of infusion solutions, including total parenteral nutrition. Dilution of 10 mL (50 mEq) in 290 mL of SW or a nonelectrolyte solution yields an isotonic (1/6 M) concentration of sodium lactate containing 167 mEq/L each of sodium and lactate anion.

Storage:

Store at CRT. Avoid freezing and excessive heat.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Must be appropriately diluted before infusion to avoid sudden increases in sodium or lactate levels. Avoid too-rapid administration and/or overdose; may produce metabolic alkalosis or hypokalemia.

Do not exceed a rate of 300 mL/hr of properly diluted solution.

ACTIONS

An alkalizing agent and sodium salt. Its activity depends on conversion to bicarbonate. In the liver, lactate is metabolized to glycogen, which is ultimately converted to CO_2 and H_2O. The sodium ion combines with bicarbonate and is retained in the body. The bicarbonate ion elevates blood pH. One liter of isotonic sodium lactate (1/6 M) is approximately equivalent to 280 mL of 5% sodium bicarbonate; however, the process of converting sodium lactate to bicarbonate takes 1 to 2 hours, and the conversion of lactate to bicarbonate is delayed if the capacity of the liver to metabolize lactate is reduced and/or in patients with tissue anoxia.

INDICATIONS AND USES

Prevention or treatment of mild to moderate metabolic acidosis in patients with restricted oral intake who have liver function adequate to oxidize sodium lactate to bicarbonate and glycogen.

CONTRAINDICATIONS

Fluid retention, hypernatremia, or other conditions in which sodium administration may be harmful. ■ May be detrimental and should not be used in the treatment of lactic acidosis. ■ Not recommended for use in conditions with elevated lactate levels (e.g., CHF, respiratory alkalosis, shock) or with diminished ability to utilize lactate (e.g., anoxia, beriberi).

PRECAUTIONS

Under optimum circumstances, sodium lactate requires 1 to 2 hours to be effective. Sodium bicarbonate is the drug of choice for use in severe acidosis that requires immediate correction and in patients in whom sodium lactate may be detrimental or ineffective. ■ May be ineffective in patients with metabolic acidosis that is associated with other disorders involving reduced perfusion of body tissues (e.g., cardiac decompensation, extracorporeal circulation, glycogen storage disease, hypothermia, liver dysfunction). ■ Temporary therapy in metabolic acidosis. Treatment of primary condition must be instituted. ■ Use with extreme caution if necessary in patients with CHF, severe renal insufficiency, or edema and sodium retention. ■ May cause sodium retention in patients with reduced renal function. ■ May cause fluid and/or solute overload and result in dilution of other serum electrolyte concentrations, overhydration, congested states, or pulmonary edema. ■ Excessive administration of potassium-free solutions may result in significant hypokalemia. ■ Use caution in patients with anuria or oliguria and if concurrent administration with corticosteroids or corticotropin is indicated.

Monitor:

Determine blood glucose, pH, Po_2,Pco_2, and electrolytes before treatment, several times daily during intensive treatment, and daily during most other situations. ■ Confirm patency of vein. ■ Monitor weight and intake and output and evaluate fluid balance. ■ Monitor patients with reduced renal function for sodium retention. ■ Monitor for S/S of alkalosis (e.g., irritability, hypokalemia [e.g., cramping, ileus, muscle weakness, polyuria], neuromuscular hyperexcitability [may be due to increased protein binding of calcium and may result in tetany]). ■ See Rate of Administration and Precautions.

Maternal/Child:

Category C: use during pregnancy only if clearly needed. ■ Not known if sodium lactate is secreted in human milk; use caution if required during breast-feeding.

Elderly:

Differences in response compared to younger adults have not been identified; however, caution and lower-end doses are suggested; see Dose Adjustments. ■ Monitoring of renal function is suggested.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Alkalosis, congestive conditions (e.g., pulmonary edema), electrolyte dilution, fluid or solute overload, hypernatremia with or without edema, hypokalemia, pain along injection site, phlebitis, thrombosis.

ANTIDOTE

Reduce rate and notify the physician at the first sign of congestion or fluid overload. Notify the physician of all side effects; most will require discontinuing the infusion. Hypokalemia usually occurs with alkalosis. Potassium must be supplemented as indicated for correction. Rebreathing expired air from a paper bag may help to control beginning symptoms of alkalosis. In overdose, discontinue the infusion. Reduction of serum sodium levels and restoring of acid-base balance is indicated. Resuscitate as necessary.

SODIUM NITRITE AND SODIUM THIOSULFATE BBW

(**SO**-dee-um **NYE**-trite, **SO**-dee-um thigh-oh-**SUL**-fayt)
Nithiodote
Antidote
pH 7 to 9 and 7.5 to 9.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

There is no widely available, rapid, confirmatory cyanide blood test. Treatment decisions must be made on the basis of clinical history and S/S of cyanide intoxication. If clinical suspicion of cyanide poisoning is high, administer Nithiodote without delay. Contact a regional poison control center to obtain advice on diagnosis and treatment of patients with suspected cyanide poisoning.

Sodium Nitrate:

10 mL (300 mg) of a 3% solution at a rate of 2.5 to 5 mL/min.

Sodium Thiosulfate:

50 mL (12.5 Gm) of a 25% solution immediately following administration of sodium nitrate. Administered in conjunction with appropriate supportive therapies; see Precautions.

Subsequent Dosing:

If signs of poisoning reappear, repeat treatment using one-half the original dose of both sodium nitrite and sodium thiosulfate.

PEDIATRIC DOSE

Sodium Nitrate:

0.2 mL/kg of body weight (6 mg/kg or 6 to 8 mL/M^2 BSA) of a 3% solution at a rate of 2.5 to 5 mL/min not to exceed 10 mL (300 mg).

Sodium Thiosulfate:

1 mL/kg of body weight (250 mg/kg or approximately 30 to 40 mL/M^2 BSA) not to exceed 50 mL (12.5 Gm) total dose using a 25% solution. Give immediately following administration of sodium nitrate.

Subsequent Dosing:

If signs of poisoning reappear, repeat treatment using one-half the original dose of both sodium nitrite and sodium thiosulfate. See all comments under Usual Dose.

DOSE ADJUSTMENTS

In adult and pediatric patients with known anemia, it is recommended that the dosage of sodium nitrite be reduced proportionately to the hemoglobin concentration. ■ Use care in dose selection in impaired renal function.

DILUTION

Nithiodote consists of one vial of sodium nitrite (300 mg/10 mL) and one vial of sodium thiosulfate (12.5 Gm/50 mL). Administration of one vial of each medication constitutes a single dose. Dilution is not required.

Filters:

No data available from the manufacturer.

Storage:

Store at CRT. Protect from direct light. Do not freeze.

COMPATIBILITY

No chemical **incompatibility** has been reported between sodium nitrite and sodium thiosulfate when administered sequentially through the same IV line. Chemical **incompatibility** has been reported between Nithiodote and hydroxocobalamin. These drugs should not be administered simultaneously through the same IV line. Simultaneous administration of Nithiodote and blood products (whole blood, packed red cells, platelet concentrate, and/or fresh frozen plasma) through the same IV line is not recommended. However, blood products and Nithiodote can be administered simultaneously using separate IV lines (preferably on contralateral extremities if peripheral lines are being used). ■ If another cyanide antidote is administered, it should not be administered concurrently in the same IV line; see Precautions.

RATE OF ADMINISTRATION

Sodium nitrite and sodium thiosulfate injection are administered by slow intravenous injection. Sodium nitrite should be administered first at a rate of 2.5 to 5 mL/min, followed immediately by sodium thiosulfate. Decrease rate of infusion if significant hypotension develops.

ACTIONS

Cyanide binds rapidly with cytochrome a3 in mitochondria. Inhibition of cytochrome a3 prevents the cell from using oxygen and forces anaerobic metabolism, resulting in lactate production, cellular hypoxia, and metabolic acidosis. Sodium nitrite reacts with hemoglobin to form methemoglobin, an oxidized form of hemoglobin incapable of oxygen transport but with a high affinity for cyanide. Cyanide preferentially binds to methemoglobin over cytochrome a3, forming nontoxic cyanomethemoglobin. Methemoglobin displaces cyanide from cytochrome oxidase, allowing resumption of aerobic metabolism. Vasodilation produced by sodium nitrite may also contribute to the therapeutic effect. Sodium thiosulfate serves as a sulfur donor in an enzymatic reaction that detoxifies cyanide. Cyanide is converted to thiocyanate, which is relatively nontoxic and readily excreted in the urine at a rate that is inversely proportional to CrCl. Following sodium nitrite administration, peak methemoglobin levels are seen at 30 to 60 minutes. The half-life for conversion of the hemoglobin to normal hemoglobin in a cyanide poisoning victim who has received Nithiodote is estimated to be 55 minutes. Sodium nitrite is metabolized to ammonia and other metabolites, and approximately 40% is excreted as unchanged drug in the urine. Most thiosulfate is oxidized to sulfate or incorporated into endogenous sulphur compounds; a small proportion is excreted in the urine. Approximately 20% to 50% of exogenously administered thiosulfate is eliminated unchanged in the urine.

INDICATIONS AND USES

Treatment of acute cyanide poisoning that is judged to be serious or life threatening. When the diagnosis of cyanide poisoning is uncertain, the potentially life-threatening risks associated with Nithiodote should be weighed against the potential benefits, especially if the patient is not in extremis.

CONTRAINDICATIONS

None.

PRECAUTIONS

Sodium nitrite can cause serious adverse reactions and death, even at doses less than twice the recommended therapeutic dose. Causes hypotension and methemoglobin formation, which diminishes oxygen-carrying capacity. Hypotension and methemoglobin formation can occur concurrently or separately. Because of these risks, sodium nitrite should be used to treat acute life-threatening cyanide poisoning and should be used with caution in patients for whom the diagnosis of cyanide poisoning is uncertain. ■ Consider alternative therapeutic approaches in patients known to have diminished oxygen or cardiovascular reserve (e.g., smoke inhalation victims, pre-existing anemia, cardiac or respiratory compromise) and in patients at higher risk for developing methemoglobinemia (e.g., congenital methemoglobin reductase deficiency); these patients are at greater risk for potentially life-threatening adverse events related to the use of sodium nitrite. ■ Supportive care alone without the administration of an antidote may be sufficient treatment in many cases of cyanide intoxication, especially in conscious patients without signs of severe toxicity. ■ Airway management, ventilatory and circulatory support, and oxygen administration should not be delayed to administer sodium nitrate and sodium thiosulfate. ■ Safety of administering other cyanide antidotes simultaneously with Nithiodote has not been established. If another cyanide antidote is administered, it should not be administered concurrently in the same IV line. ■ Sodium nitrite should be used with caution in patients who may be susceptible to injury from vasodilation and its related hemodynamic sequelae. ■ Use sodium nitrite with caution in patients with known anemia. Patients with anemia will form more methemoglobin (as a percentage of total hemoglobin) than persons with normal red blood cell volumes; see Dose Adjustments. ■ Sodium nitrite should be used with caution in persons with smoke inhalation injury or carbon monoxide poisoning because of the potential for worsening hypoxia due to methemoglobin formation. ■ Use with caution and consider possible alternative therapies in patients with G6PD deficiency. These patients are at increased risk for hemolytic crisis with sodium nitrite administration. If Nithiodote is required, monitor for an acute drop in hematocrit. Exchange transfusion may be needed for patients with G6PD deficiency who receive sodium nitrite. ■ Risk of toxicity may be greater in patients with impaired renal function. ■ Sodium thiosulfate may contain trace impurities of sodium sulfite. This should not deter the administration of Nithiodote for treatment of emergency situations, even if the patient is sulfite-sensitive. ■ See Drug/Lab Interactions.

Monitor:

Monitor patients for at least 24 to 48 hours after Nithiodote administration to ensure adequate perfusion and oxygenation and to watch for S/S of recurrent cyanide toxicity (e.g., altered mental status [confusion, disorientation], bradypnea/apnea, cardiovascular collapse, chest tightness, coma, dyspnea, headache, hypertension, hypotension, mydriasis, nausea, plasma lactate concentration equal to or greater than 8 mmol/L, seizures, tachypnea/hyperpnea, vomiting). ■ Obtain baseline BP and HR and monitor throughout infusion. Decrease rate of infusion if significant hypotension is noted. ■ Obtain baseline hemoglobin and hematocrit, if possible. ■ Monitor serum methemoglobin levels using co-oximetry. It is recommended that methemoglobin concentrations be kept below 30%. Discontinue administration of sodium nitrite when methemoglobin levels exceed 30%; see Antidote. ■ Measurements of oxygen saturation using standard pulse oximetry and calculated oxygen saturation values based on measured PO_2 are unreliable in the presence of methemoglobinemia.

Patient Education:

Inform patient of the need for close monitoring of BP and oxygenation status. ■ Nithiodote is indicated for cyanide poisoning and, in this setting, patients will likely be unresponsive or may have difficulty comprehending counseling information. When feasible, inform patient of the possibility of life-threatening hypotension and methemoglobin formation.

Maternal/Child:

Category C: use during pregnancy and labor and delivery only if potential benefit justifies potential risk to the fetus. Sodium nitrite has caused fetal death. Sodium nitrite produces methemoglobin. Fetal hemoglobin is oxidized to methemoglobin more easily than adult hemoglobin. In addition, the fetus has lower levels of methemoglobin reductase than adults. Collectively, this suggests that the human fetus would show greater sensitivity to methemoglobin, resulting in nitrite-induced prenatal hypoxia and leading to delayed development of certain neurotransmitter systems in the brain and long-lasting dysfunction. ■ Use caution in breast-feeding. Because Nithiodote is administered in a life-threatening situation, breast-feeding is not a contraindication to use. There are no data to determine when breast-feeding may be safely restarted following administration of Nithiodote. ■ There are no clinical studies to evaluate the safety or efficacy of Nithiodote in pediatric patients; however, it has been used. ■ Use with caution in patients under 6 months of age. Neonates and infants may be more susceptible than adults and older pediatric patients to severe methemoglobinemia when sodium nitrite is administered. Follow reduced dosing guidelines in pediatric patients. The presence of fetal hemoglobin and lower methemoglobin reductase levels may contribute to the risk.

Elderly:

Sodium nitrite and sodium thiosulfate are both substantially excreted by the kidney. Risk of toxicity may be greater in patients with impaired renal function. Because elderly patients are more likely to have decreased renal function, care should be taken in dose selection, and it may be useful to monitor renal function.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Sodium nitrite should be used with caution in the presence of other drugs that may cause methemoglobinemia, such as **procaine** and **nitroprusside**. ■ Use sodium nitrite with caution in the presence of concomitant **antihypertensive medications, diuretics** or volume depletion due to diuretics, or drugs known to increase vascular nitric oxide such as **PDE5 inhibitors** (sildenafil [Revatio,Viagra], tadalafil [Cialis]).

SIDE EFFECTS

No controlled clinical trials have been conducted to assess the adverse events profile of sodium nitrite or sodium thiosulfate. The following side effects have been reported in the literature.

Sodium nitrite:

The most common side effects include blurred vision, coma, confusion, dizziness, dysrhythmia, headache, hypotension, methemoglobinemia, palpitations, seizures, syncope, and tachycardia. Abdominal pain, acidosis, anxiety, cyanosis, diaphoresis, dyspnea, fatigue, generalized numbness and tingling, injection site tingling, lightheadedness, nausea, tachypnea, urticaria, vomiting, and weakness have also been reported. Severe hypotension, methemoglobinemia, cardiac dysrhythmias, coma, and death have been reported in patients without life-threatening cyanide poisoning who were treated with injection of sodium nitrite at doses less than twice those recommended for the treatment of cyanide poisoning.

Sodium thiosulfate:

Disorientation, headache, and hypotension are most common. Nausea, prolonged bleeding time, salty taste in the mouth, vomiting, and a warm sensation over the body have also been reported. Rapid administration of concentrated solutions or solutions not freshly prepared and administration of large doses of sodium thiosulfate have been associated with a higher incidence of nausea and vomiting. An increased clotting time may occur 1 to 3 days after sodium thiosulfate administration.

Overdose:

CNS depression, severe hypotension, and toxic levels of methemoglobin that may lead to cardiovascular collapse.

ANTIDOTE

Keep physician informed of all side effects. Treatment of overdose includes supplemental oxygen and supportive measures such as exchange transfusions. Intravenous methylene blue and exchange transfusion have been reported in the literature as treatments for life-threatening methemoglobinemia. However, the administration of methylene blue may also cause the release of cyanide bound to methemoglobin. Treat hypotension with standard agents (e.g., dopamine, norepinephrine).

SODIUM PHENYLACETATE AND SODIUM BENZOATE

(**SO-**dee-um fen-ill-**AH-**seh-tate and **SO-**dee-um **BEN-**zoh-ate)
Ammonul
Ammonia detoxicant
pH 6 to 8

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Must be diluted and administered through a central line. Administration through a peripheral line may cause burns. Given in combination with arginine (dose is dependent on the specific urea cycle disorder [UCD] and is contraindicated in patients with arginase deficiency); see Dilution, Rate of Administration, Precautions, and Monitor. Urea cycle disorders can result from decreased activity of any of the following enzymes: *N*-acetylglutamate synthetase (NAGS), carbamyl phosphate synthetase (CPS), argininosuccinate synthetase (ASS), ornithine transcarbamylase (OTC), argininosuccinate lyase (ASL), or arginase (ARG); dose and treatment may vary for each. Sodium phenylacetate and sodium benzoate (Ammonul) infusion should be started as soon as the diagnosis of hyperammonemia is made.

Discontinue analogous oral drugs (e.g., sodium phenylbutyrate [Buphenyl]) before sodium phenylacetate and sodium benzoate (Ammonul) infusion.

A **loading dose** as an infusion is administered over 90 to 120 minutes, followed by an **equivalent maintenance dose** as an infusion administered over 24 hours. Treatment also requires caloric supplementation and restriction of dietary protein. Nonprotein calories should be supplied principally as glucose (8 to 10 mg/kg/min), with intravenous fat (e.g., Intralipid) added to maintain a caloric intake of greater than 80 cal/kg/day.

The dose of sodium phenylacetate and sodium benzoate (Ammonul) is based on mg/kg in neonates, infants, and younger pediatric patients weighing up to 20 kg and on body surface area for older pediatric patients, adolescents, and adults weighing more than 20 kg as described in the following chart.

Dose and Administration Guidelines for Sodium Phenylacetate and Sodium Benzoate (Ammonul)					
Patient Population	**Components of Infusion SolutionAmmonul must be diluted with D10W at equal to or greater than 25 mL/kg before administration**		**Dosage Provided**		
	Ammonul	**Arginine HCl Injection, 10%**	**Sodium Phenylacetate**	**Sodium Benzoate**	**Arginine HCl**
WEIGHT EQUAL TO OR LESS THAN 20 KG:					
CPS and OTC Deficiency					
Loading dose: Over 90 to 120 minutes **Maintenance:** Over 24 hours	2.5 mL/kg	2 mL/kg	250 mg/kg	250 mg/kg	200 mg/kg
ASS and ASL Deficiency					
Loading dose: Over 90 to 120 minutes **Maintenance:** Over 24 hours	2.5 mL/kg	6 mL/kg	250 mg/kg	250 mg/kg	600 mg/kg
WEIGHT MORE THAN 20 KG:					
CPS and OTC Deficiency					
Loading dose: Over 90 to 120 minutes **Maintenance:** Over 24 hours	55 mL/M^2	2 mL/kg	5.5 Gm/M^2	5.5 Gm/M^2	200 mg/kg
ASS and ASL Deficiency					
Loading dose: Over 90 to 120 minutes **Maintenance:** Over 24 hours	55 mL/M^2	6 mL/kg	5.5 Gm/M^2	5.5 Gm/M^2	600 mg/kg

Repeat loading doses should not be administered because plasma levels achieved by phenylacetate are prolonged. Continue maintenance infusions until elevated plasma ammonia levels have been normalized or oral nutrition and medications can be tolerated. Mean duration of treatment was 4.6 days per episode and ranged from 1 to 72 days.

DOSE ADJUSTMENTS

No specific recommendations; see Precautions.

DILUTION

Must be diluted with D10W. Do not administer undiluted product.

Loading dose:

Dilute with an amount of D10W equal to or more than 25 mL/kg of body weight per dose.

Equivalent maintenance dose:

Also requires dilution with an amount of D10W equal to or more than 25 mL/kg of body weight per dose.

A 4-kg neonate would require a minimum of 100 mL of D10W for dilution of the loading dose given over 90 to 120 minutes and a minimum of 100 mL of D10W for dilution of the maintenance dose given over 24 hours. An 80-kg adult would require a minimum of 2,000 mL of D10W for dilution of the loading dose over 90 to 120 minutes and a minimum of 2,000 mL D10W for dilution of the maintenance dose given over 24 hours.

Filters:

Use of a 0.22-micron filter has been used to inject Ammonul into D10W.

Storage:

Store unopened vials at CRT. Diluted solutions are stable at CRT and room lighting conditions for up to 24 hours.

COMPATIBILITY

May be mixed in the same container with 10% arginine HCl injection. Manufacturer states, "Other infusion solutions and drug products should not be administered together with sodium phenylacetate and sodium benzoate." May be prepared in glass or PVC containers.

RATE OF ADMINISTRATION

Loading dose infusion rates are relatively high, especially for infants; monitor closely.

Loading dose:

A single dose properly diluted as an infusion and equally distributed over 90 to 120 minutes.

Maintenance dose:

Each single dose properly diluted as an infusion and equally distributed over 24 hours.

ACTIONS

Sodium phenylacetate and sodium benzoate are metabolically active compounds that can provide an alternative pathway for nitrogen disposal in patients without a fully functioning urea cycle. Two moles of nitrogen are removed per mole of phenylacetate when it is conjugated with glutamine, and one mole of nitrogen is removed per mole of benzoate when it is conjugated with glycine. Has been shown to decrease elevated plasma ammonia levels. Considered to be the result of the reduction in nitrogen overload through glutamine and glycine scavenging by sodium phenylacetate and sodium benzoate (Ammonul) in combination with appropriate dietary and other supportive measures.

Phenylacetate:

Conjugates with glutamine in the liver and kidneys to form phenylacetylglutamine. It is then excreted by the kidneys via glomerular filtration and tubular secretion. Each mole of phenylacetylglutamine contains two moles of waste nitrogen. The nitrogen content of phenylacetylglutamine per mole is identical to that of urea (2 moles of nitrogen). Plasma levels remain higher and are present for a longer period of time than plasma levels of benzoate.

Benzoate:

Conjugates with glycine to form hippuric acid, which is rapidly excreted by the kidneys by glomerular filtration and tubular secretion. One mole of hippuric acid contains one mole of waste nitrogen. The formation of hippurate from benzoate occurs more rapidly than that of phenylacetylglutamine from phenylacetate, and the rate of elimination of hippurate appears to be more rapid than that of phenylacetylglutamine.

INDICATIONS AND USES

Adjunctive therapy for the treatment of acute hyperammonemia and associated encephalopathy in adult and pediatric patients with deficiencies in enzymes of the urea cycle. UCDs can result from decreased activity of any of the following enzymes: *N*-acetylglutamate synthetase (NAGS), carbamyl phosphate synthetase (CPS), argininosuccinate synthetase (ASS), ornithine transcarbamylase (OTC), argininosuccinate lyase (ASL), or arginase (ARG). In acute hyperammonemic episodes, arginine supplementation, caloric supplementation, dietary protein restriction, hemodialysis, and other ammonia-lowering therapies should be considered.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For IV infusion only. Must be infused through a central line. Administration through a peripheral line may cause burns. ■ Acute symptomatic hyperammonemia should be treated as a life-threatening emergency. Treatment may require hemodialysis to remove a large burden of ammonia. Uncontrolled hyperammonemia can rapidly result in brain damage or death, and prompt use of all therapies necessary to reduce ammonia levels is essential. ■ Administered under the direction of a physician knowledgeable in its use and in the treatment of diseases resulting from inborn errors in metabolism. Should be administered in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. In addition, facilities for hemodialysis, nutritional support, and medical support are required. ■ Patients with a large ammonia burden or patients who are not responsive to sodium phenylacetate and sodium benzoate (Ammonul) require aggressive therapy, including hemodialysis. ■ Metabolized in the liver and kidneys and excreted by the kidneys. Use caution in patients with impaired renal or hepatic function. ■ Use with extreme caution, if at all, in patients with CHF or severe renal insufficiency and in clinical states in which there is sodium retention with edema; contains 30.5 mg of sodium/mL of undiluted product; see Antidote. ■ Bioavailability of both benzoate and phenylacetate may be slightly higher in females than in males. ■ See Monitor, Maternal/Child, and Drug/Lab Interactions.

Monitor:

Plasma and urine amino acid analyses are used to diagnose ASS and ASL and to provide a preliminary diagnosis of CPS, OTC, or ARG. Blood citrulline levels are very low or absent in OTC and CPS, very high in ASS, and normal to moderately high in ASL and ARG. High urine levels of an unusual amino acid (argininosuccinic acid [ASA]) may distinguish ASL; however, ASA may be difficult to detect on initial examination. Specific studies are required to separate it from other amino acids. ARG is characterized by high urine levels of arginine. A liver biopsy is indicated for definitive diagnosis of CPS and OTC. RBC enzyme analysis is needed to confirm a diagnosis of ARG. ■ Monitor catheter infusion site closely. Extravasation may lead to skin necrosis. If extravasation is suspected, discontinue the infusion and, if necessary, resume at a different site. ■ Monitor plasma ammonia, glutamine, quantitative plasma amino acids, blood glucose, ABGs, AST, and ALT during and after infusion. ■ Ongoing assessment of clinical response includes monitoring of neurologic status, Glasgow Coma Scale, tachypnea, CT or MRI scan or fundoscopic evidence of cerebral edema, and/or gray matter and white matter damage. In patients responding to therapy, mean ammonia levels decreased significantly within 4 hours of initiation of therapy. ■ May be used in combination with dialysis. Hemodialysis is the most commonly used and can either be instituted immediately while waiting for a more definitive diagnosis or used as a recommended addition to treatment for those patients who fail to have a significant reduction in plasma ammonia levels within 4 to 8 hours after receiving sodium phenylacetate and sodium benzoate (Ammonul). High levels of ammonia can be reduced quickly when sodium phenylacetate and sodium benzoate (Ammonul) is used with dialysis. The ammonia scavenging of sodium phenylacetate and sodium benzoate (Ammonul) suppresses the production of ammonia from catabolism of endogenous protein, and dialysis eliminates the ammonia and ammonia conjugates. ■ Monitor serum electrolytes and maintain within normal range. Monitor plasma potassium levels carefully and treat as indicated; urine potassium loss is enhanced by excretion of the nonresorbable anions phenylacetylglutamine and hippurate. ■ May cause side effects associated with salicylate overdose (e.g., hyperventilation, metabolic acidosis). Obtain baseline and monitor blood chemistry profiles, blood pH, and P_{CO_2}. ■ Use with high-dose arginine may cause hyperchloremic acidosis. Obtain baseline and monitor chloride and bicarbonate levels; administer bicarbonate as indicated. ■ Use prophylactic antiemetics to reduce nausea and vomiting. ■ Neurotoxicity has been reported (e.g., disorientation, exacerbation of a pre-existing neuropathy, fatigue, headaches, hypoacusis [partial loss of hearing], impaired memory, light-headedness, somnolence).

Onset may be acute, and symptoms should improve when therapy is discontinued. ■ Closely monitor patients with impaired renal function; drug therapy may be less effective due to poor clearance of drug metabolites and, subsequently, ammonia. ■ See Precautions, Maternal/Child, and Drug/Lab Interactions.

Patient Education:

Compliance with dietary restrictions and supplemental medications is imperative. ■ Obtain identification (e.g., a bracelet) with UCD diagnosis.

Maternal/Child:

Category C: use during pregnancy and/or labor and delivery only if clearly needed. Effects on fetus unknown. ■ Not known if it is secreted in human milk; use caution if required during breast-feeding. Has the potential for serious harm to infant. ■ Is used as a treatment for acute hyperammonemia in pediatric patients, including patients in the early neonatal period. ■ The most commonly presented symptoms of UCD in neonates include edema, lethargy, neurologic changes, poor feeding, respiratory distress, and seizures. Milder forms of UCDs may not present until late childhood, adolescence, or adulthood. Symptoms, including hyperammonemic crisis with coma, delirium, and/or lethargy, are often precipitated by viral illness, high-protein diet, stress, or trauma.

Elderly:

Relevant information not available. Oldest patient in studies was 53 years of age. Average age in studies was 8.54 years. ■ Monitoring of renal and hepatic function is suggested.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. ■ Concurrent use with **corticosteroids** (e.g., dexamethasone [Decadron]) may cause the breakdown of body protein and increase plasma ammonia levels in patients with an impaired ability to form urea. ■ Some **antibiotics** (e.g., penicillin) may compete with phenylacetylglutamine and hippurate for active secretion by renal tubules. This competition may affect the overall disposition of either of the infused drugs. ■ **Probenecid** is known to inhibit the renal transport of many drugs and may inhibit the renal excretion of phenylacetylglutamine and hippurate, reducing its effectiveness. ■ **Valproic acid** has been reported to induce hyperammonemia. Administration to patients with UCD may exacerbate their condition and antagonize the effectiveness of sodium phenylacetate and sodium benzoate (Ammonul).

SIDE EFFECTS

The most commonly reported side effects include convulsions, hyperglycemia, hypokalemia, mental impairment, and vomiting. Acidosis, agitation, anemia, coma, diarrhea, DIC, edema of the brain, fever, hyperammonemia, hypocalcemia, hypotension, injection site reactions, metabolic acidosis, nausea, respiratory distress, and urinary tract infections were also reported frequently. Injection site reactions and metabolic acidosis were dose-limiting reactions in several patients. Incidence and severity of side effects tend to be increased in patients with enzyme deficiencies occurring earlier in the urea cycle (i.e., OTC and CPS). Incidence of side effects was also specific to age and diagnosis as follows.

Pediatric patients 30 days of age or less:

Blood and lymphatic system disorders (e.g., anemia, DIC) and hypotension.

Patients more than 30 days of age:

GI disorders (e.g., diarrhea, nausea, and vomiting).

Patients with OTC, ASS, CPS, and diagnoses characterized as other:

Side effects were primarily the ones most frequently reported.

Patients with OTC and CPS:

Nervous system disorders (e.g., coma, convulsions, edema of the brain, mental impairment) were most common.

Overdose:

Cardiovascular collapse, encephalopathy (progressive), hypernatremia, hyperosmolarity, hyperventilation, large anion gap, metabolic acidosis (severe and compensated) with a respiratory component, obtundation (in the absence of hyperammonemia), and death. Causes of death from overdose were cardiorespiratory failure/arrest, error in dialysis procedure, hyperammonemia, hypotension (intractable) with probable sepsis, increased intracranial pressure, pneumonitis with septic shock and coagulopathy.

ANTIDOTE

Keep physician informed of all side effects. Many may be life threatening and immediate, and appropriate treatment is required. If an adverse reaction occurs due to sodium content, discontinue infusion, evaluate the patient, and treat as indicated. If extravasation is suspected, discontinue the infusion and, if necessary, resume at a different site. Treat extravasation by aspirating the residual drug from the catheter, elevating the limb (if a limb is involved), and applying intermittent cold packs. If overdose occurs, discontinue the drug, and monitor and treat as indicated by symptoms. In severe cases, hemodialysis (procedure of choice) and/or peritoneal dialysis (when hemodialysis is not available) may be indicated. Resuscitate as indicated.

SOTALOL HYDROCHLORIDE BBW

(**SO**-tuh-lol hy-droh-**KLOR**-eyed)
Beta-adrenergic blocking agent
Antiarrhythmic
pH 6 to 7

USUAL DOSE

Pretreatment:

Baseline ECG indicated; see Monitor.

To minimize the risk of induced arrhythmia, patients initiated or re-initiated on sotalol and patients who are converted from IV to oral administration should be hospitalized in a facility that can provide cardiac resuscitation and continuous ECG monitoring. CrCl must be greater than 60 mL/min. Baseline studies and correction of electrolyte abnormalities required before initiating therapy; see Precautions, Monitor, and Dose Adjustments.

Initial dose:

75 mg twice daily. If symptomatic arrhythmia is not controlled and dose is tolerated without excessive QTc prolongation (i.e., greater than 500 msec), may increase dose to 112.5 mg twice daily after 3 days. Continuous ECG monitoring required during dose escalation.

Dose for ventricular arrhythmias:

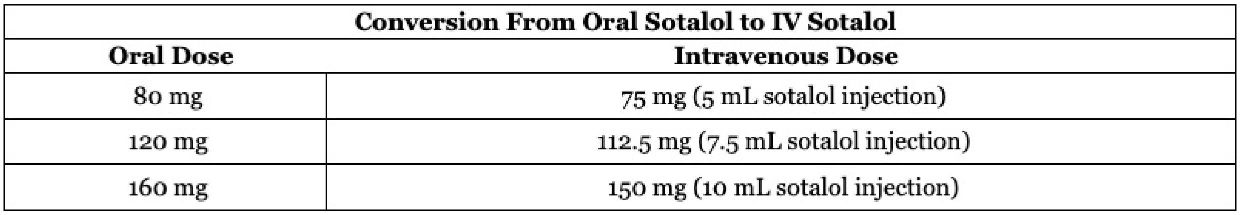
75 mg twice daily. Dose may be increased in increments of 75 mg/day every 3 days. Usual therapeutic effect is seen with doses of 75 to 150 mg twice daily. However, doses as high as 225 to 300 mg have been required in patients with refractory life-threatening arrhythmias.

Dose for symptomatic atrial fibrillation/atrial flutter (AFIB/AFL):

112.5 mg twice daily was found to be the most effective dose in studies. If symptomatic arrhythmia is not controlled and this dose is tolerated without excessive QTc prolongation (i.e., greater than 520 msec), increase dose to 150 mg twice daily.

Conversion from oral to intravenous sotalol:

Patients who have been stabilized on oral sotalol and are unable to take oral medications may be converted to IV sotalol using the following conversion chart.



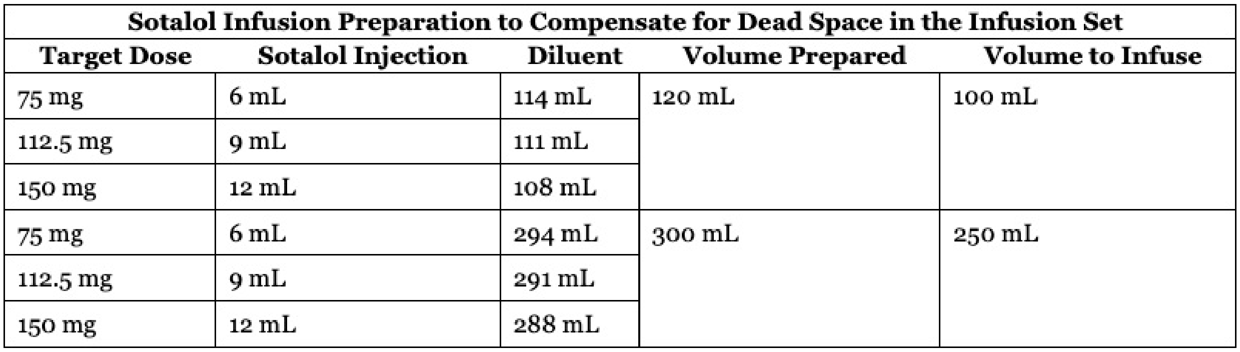
Conversion From Oral Sotalol to IV Sotalol	
Oral Dose	**Intravenous Dose**
80 mg	75 mg (5 mL sotalol injection)
120 mg	112.5 mg (7.5 mL sotalol injection)
160 mg	150 mg (10 mL sotalol injection)

DOSE ADJUSTMENTS

Increase dosing interval to every 24 hours in patients with a CrCl between 40 and 60 mL/min. Sotalol is not recommended in patients with a CrCl less than 40 mL/min. ■ Titrate dose upward or downward as needed based on clinical effect, QT interval, or adverse reactions as described in Usual Dose.

DILUTION

Available in vials containing 150 mg/10 mL. Dilute required dose with NS, D5W, or LR as described in the following chart.



Sotalol Infusion Preparation to Compensate for Dead Space in the Infusion Set

Target Dose	Sotalol Injection	Diluent	Volume Prepared	Volume to Infuse
75 mg	6 mL	114 mL	120 mL	100 mL
112.5 mg	9 mL	111 mL		
150 mg	12 mL	108 mL		
75 mg	6 mL	294 mL	300 mL	250 mL
112.5 mg	9 mL	291 mL		
150 mg	12 mL	288 mL		

Storage:

Store at CRT. Protect from light and freezing.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose equally distributed over 5 hours. Use of an infusion pump recommended.

ACTIONS

An antiarrhythmic with Class II (beta-adrenoreceptor blocking) and Class III (cardiac action potential duration prolongation) properties. The beta-blocking effect is noncardioselective. Slows heart rate, decreases AV nodal conduction, and increases AV nodal refractoriness. ECG shows dose-related increase in QT and QTc. Produces a reduction in systolic and diastolic blood pressures and cardiac index and an increase in pulmonary capillary wedge pressure. Does not bind to plasma proteins and is not metabolized. Half-life is 12 hours. Excreted predominantly via the kidney in unchanged form. Crosses the placenta. Secreted in breast milk.

INDICATIONS AND USES

A substitute for oral sotalol in patients who are unable to take oral medications. ■ Maintenance of normal sinus rhythm in patients with a history of highly symptomatic AFIB/AFL. ■ Treatment of documented life-threatening ventricular arrhythmias.

CONTRAINDICATIONS

Bradycardia (HR below 50 beats/min), sick sinus syndrome, or second- or third-degree AV block unless a functioning pacemaker is present. ■ Congenital or acquired long QT syndromes, QT interval greater than 450 msec. ■ Cardiogenic shock, uncontrolled heart failure. ■ CrCl less than 40 mL/min. ■ Serum potassium less than 4 mEq/L. ■ Bronchial asthma or related bronchospastic conditions. ■ Known hypersensitivity to sotalol.

PRECAUTIONS

To minimize the risk of induced arrhythmia, patients initiated or re-initiated on sotalol and patients who are converted from IV to oral administration should be hospitalized for at least 3 days (or until steady-state drug levels are reached) in a facility that can provide cardiac resuscitation and continuous ECG monitoring. Personnel trained in the management of serious ventricular arrhythmias must be present. ■ Can cause serious ventricular arrhythmias, primarily torsades de pointes (TdP), a polymorphic ventricular tachycardia associated with QTc prolongation. QTc prolongation is directly related to the concentration of sotalol. Factors that may increase the risk of TdP include a reduced CrCl, larger doses, female gender, sustained VT, and a history of cardiomegaly or CHF. ■ The use of sotalol in conjunction with other drugs that prolong the QT interval has not been studied and is not recommended; see Drug/Lab Interactions. ■ May cause bradycardia, which increases risk of TdP. ■ Increased risk of TdP in patients with AFIB and sinus node dysfunction, especially after cardioversion. Sotalol increases bradycardia and QTc following cardioversion. ■ Produces significant reductions in both systolic and diastolic BP. May cause deterioration in cardiac performance in patients with marginal cardiac compensation. ■ Use caution in CHF. Beta blockade may depress myocardial contractility and precipitate or exacerbate heart failure. ■ Use caution in the presence of heart failure controlled by digoxin. Both drugs slow AV conduction. ■ Experience with use following acute MI is limited. Use caution, titrate dose carefully, and monitor patient closely. ■ May cause angina, arrhythmia, or MI if discontinued abruptly; gradually reduce over 1 to 2 weeks if possible. ■ May mask tachycardia occurring with hypoglycemia in diabetes and tachycardia of hyperthyroidism. ■ In general, patients with bronchospastic disease should not receive beta-blockers. If sotalol is to be administered, use the smallest effective dose; see Contraindications. ■ Use caution in patients with renal impairment; see Dose Adjustments. ■ Patients with atrial fibrillation should be anticoagulated according to usual medical practice.

Monitor:

Obtain baseline ECG to determine the QT interval. If baseline QT interval is greater than 450 msec, sotalol is not recommended. Monitor QT interval after the completion of each infusion. ■ Measure and normalize serum potassium and magnesium levels before initiating therapy and as required during therapy. Pay special attention to electrolytes and acid-base status in patients with prolonged diarrhea or in patients receiving concomitant diuretics. ■ Obtain baseline SCr and calculate CrCl to establish dosing interval. ■ Monitor HR and BP. Monitor hemodynamics in patients with marginal cardiac compensation. ■ In patients with life-threatening ventricular arrhythmias, the response to treatment should be evaluated by a suitable method (e.g., programmed electrical stimulation [PES] or Holter monitoring) at steady-state blood levels of the drug before continuing the patient on chronic therapy.

Patient Education:

Do not discontinue therapy abruptly. ■ Promptly report any breathing difficulty, syncope, or pain at injection site.

Maternal/Child:

Category B: use during pregnancy only if clearly needed. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established. See prescribing information for unlabeled suggested oral doses for use in pediatric patients.

Elderly:

Age-related differences in safety and effectiveness not identified; however, greater sensitivity of some elderly cannot be ruled out. Dose with caution, taking into account decreased renal function; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Proarrhythmic events were more common in sotalol-treated patients also receiving **digoxin.** Unclear as to whether this is a drug interaction or is related to the presence of heart failure, which is a known risk factor for arrhythmias. ■ Concurrent use with **calcium channel blockers** is expected to have additive effects on AV conduction, ventricular function, and BP. ■ Beta-adrenergic blocking agents may be continued during the perioperative period in most patients; however, use caution with **selected anesthetic agents** that may depress the myocardium. Protracted severe hypotension and difficulty in restoring and maintaining normal cardiac rhythm after anesthesia have been reported. ■ Concurrent use with **clonidine** may precipitate acute hypertension if one or both agents are stopped abruptly. ■ Coadministration with **catecholamine-depleting drugs** (e.g., reserpine and guanethidine) may result in hypotension, bradycardia, vertigo, syncope, or orthostatic hypotension. ■ Hyperglycemia may occur. Dosage of **insulin and other antidiabetic drugs** may require adjustment. ■ Symptoms of **hypoglycemia may be masked.** ■ Increased doses of **beta-agonists** such as albuterol, terbutaline, and isoproterenol may be required when administered concomitantly with sotalol. ■ Patients taking **beta-blockers** who are exposed to a potential allergen may be unresponsive to the usual dose of epinephrine used to treat a hypersensitivity reaction. ■ The use of sotalol in conjunction with other **drugs that prolong the QT interval** has not been studied and is not recommended. Such drugs include some phenothiazines, tricyclic antidepressants, oral macrolide antibiotics, Class I antiarrhythmics (e.g., disopyramide, procainamide, quinidine), and Class III antiarrhythmics (e.g., amiodarone). **Class I and III antiarrhythmic agents** should be withheld for at least three half-lives before dosing with sotalol. ■ The presence of sotalol in the urine may result in **falsely elevated levels of urinary metanephrine** by certain methods.

SIDE EFFECTS

There is no clinical experience with IV sotalol. Side effects should be similar to those seen with oral sotalol therapy. The most common side effects (dose related) are asthenia, bradycardia, chest pain, dizziness, dyspnea, fatigue, headache, light-headedness, nausea, palpitations, and QT prolongation. Ventricular arrhythmia, primarily TdP, is the most common serious side effect. Other reported side effects include abdominal distension and pain, abnormal ECG, angina, bradycardia, cough, decreased appetite, diarrhea, dyspepsia, edema, fever, heart failure, hyperhidrosis, hypotension, infection, insomnia, musculoskeletal pain, tracheobronchitis, upper respiratory infection, visual disturbance, vomiting, and weakness. Other reactions have been reported.

Overdose:

Bradycardia, bronchospasm, cardiac asystole, CHF, hypoglycemia, hypotension, premature ventricular complexes, prolongation of the QT interval, TdP, and ventricular arrhythmia.

ANTIDOTE

Notify physician of any side effects. If the QT interval increases to 500 msec or greater, reduce the dose, decrease the infusion rate, or discontinue therapy. Atropine, another anticholinergic drug, a beta-adrenergic agonist, or transvenous cardiac pacing may be used to treat bradycardia or cardiac asystole. A transvenous cardiac pacemaker may be required for second- or third-degree heart block. Epinephrine may be useful for treatment of hypotension. Aminophylline or aerosol beta-2–receptor stimulants (e.g., albuterol) may be useful for treatment of bronchospasm. DC cardioversion, magnesium sulfate, and potassium replacement may be required for treatment of TdP. Once TdP is terminated, transvenous cardiac pacing or an isoproterenol infusion may be used to increase heart rate.

SPESOLIMAB

(**SPES**-o-**LI**-mab)
Spevigo
Interleukin-36 receptor antagonist; monoclonal antibody

USUAL DOSE

900 mg IV once; if flare persists, an additional 900 mg IV may be given 1 week later.

PEDIATRIC DOSE

Not established

DOSE ADJUSTMENTS

Renal:

No dosage adjustments are provided by the manufacturer.

Hepatic:

No dosage adjustments are provided by the manufacturer.

DILUTION

IV Infusion:

Draw out 15 mL from a 100-mL NS bag and discard the 15 mL. Slowly add 15 mL of spesolimab (complete contents from two 450-mg/7.5 mL vials) to the 100-mL NS bag and mix gently. Use immediately after dilution. The solution in the vials should be clear to slightly opalescent and colorless to slightly brownish-yellow. Do not use a vial if it is cloudy or discolored or contains large or colored particulates. Protect from light.

COMPATIBILITY

Do not administer simultaneously with any other medications or IV solutions other than normal saline.

RATE OF ADMINISTRATION

For IV infusion only; must be diluted prior to administration as listed above. Flush line with NS before and after infusion. Administer by IV infusion over 90 minutes using a sterile, non-pyrogenic, low-protein-binding in-line filter (0.2 micrometer). Do not give other medications through the same line as the spesolimab infusion. If an infusion reaction occurs, immediately stop the infusion. For mild to moderate reactions, once symptoms resolve, resume infusion at a slower rate and gradually increase rate to complete infusion. The total infusion time (including stop time) should not exceed 180 minutes.

ACTIONS

Spesolimab is a humanized monoclonal antibody that binds to the interlukin-36 receptor and prevents binding of endogenous IL-36 which in turn prevents activation of proinflammatory and profibrotic pathways by IL-36. The precise role of reduced IL-36 activity in pustular psoriasis is unknown.

INDICATIONS AND USES

Treatment of generalized pustular psoriasis flares in adults

CONTRAINDICATIONS

Severe or life-threatening hypersensitivity to spesolimab or any component of the formulation

PRECAUTIONS

Guillain-Barré syndrome has been reported. Hypersensitivity reactions have been reported and may include anaphylaxis or drug reaction with eosinophilia and systemic reactions. Discontinue treatment if anaphylaxis or other serious allergic reactions occur; ensure the availability of medications for treatment of hypersensitivity reactions during administration. Spesolimab may increase the risk of bacterial or viral infections, especially in patients with a history of recurrent or chronic infections. Avoid use in patients with active infection until it resolves or has been adequately treated. Screen for latent tuberculosis infection. Safety has not been established in patients with active tuberculosis. Avoid use of live vaccines.

Monitor:

Infusion-related reactions (hematoma, bruising) and S/S of hypersensitivity, anaphylaxis, or infection during and after the infusion

Patient Education:

Notify provider of any signs of allergic reaction. Spesolimab may cause weakness, upset stomach, or throwing up, as well as headache, diarrhea, bruising, swelling, and warmth or redness at the injection site. Notify provider of infection (fever, chills, sore throat, ear or sinus pain, cough, more sputum or change in color of sputum, pain while passing urine, mouth sores or wounds that do not heal). UTI (blood in urine, burning or pain when passing urine, fever, feeling the need to pass urine more often, pelvic pain, vaginal itching or discharge, fever, rash, or swollen glands).

Maternal/child:

Spesolimab crosses the placenta. It is not known if spesolimab is present in breast milk. According to the manufacturer, the decision to breastfeed during therapy is based on risk versus benefit.

Elderly:

No specific recommendations; refer to adult dosing.

DRUG/LAB INTERACTIONS

Avoid live vaccine and other immunosuppressants. Monitor with denosumab, efgartigimod, ocrelizumab, or pidotimod. May decrease effectiveness of COVID-19, influenza, pneumococcal, and other vaccines.

SIDE EFFECTS

Infection, cellulitis, herpes simplex dermatitis, pruritus, pustules, urticaria, nausea, vomiting, oral herpes simplex infection, bacteriuria, UTI, antibody development, bacteremia, injection site reaction, asthenia, fatigue, headache, periorbital edema, dyspnea, upper respiratory tract infection, or hypersensitivity

ANTIDOTE

There is no antidote; stop infusion for hypersensitivity reactions and treat appropriately.

STREPTOKINASE

(strep-toe-**KYE**-nayz)
Streptase 🍁
Thrombolytic agent
pH 6 to 8

USUAL DOSE (International units [IU])

Pretreatment:

Baseline studies indicated; see Monitor.

Some clinicians suggest premedication with hydrocortisone sodium succinate or methylprednisolone (Solu-Medrol) 100 mg IV and diphenhydramine 50 mg IV to decrease the risk of severe hypersensitivity and febrile reactions.

Coronary artery thrombi:

1.5 million IU direct IV within 6 hours of onset of symptoms of acute transmural myocardial infarction. An alternative is 20,000 IU given directly into the coronary artery within 6 hours of onset of symptoms of acute transmural myocardial infarction. Follow with 2,000 IU/min for 1 hour. Total dose equals 140,000 IU. Other protocols are in use. Recent studies suggest that other thrombolytics (e.g., alteplase [tPA]) may be preferred.

Deep vein thrombosis, pulmonary or arterial embolism, arterial thrombosis:

Loading dose: 250,000 IU. ***Maintenance dose:*** 100,000 IU/hr for 24 to 72 hours depending on diagnosis. May be increased based on thrombin time evaluations.

Arteriovenous cannula occlusion:

100,000 to 250,000 IU into each occluded limb of cannula. See Contraindications.

PEDIATRIC DOSE

Thromboembolism or acute arterial thrombosis (unlabeled use):

1,000 IU (up to 3,000 IU)/kg of body weight over 5 to 30 minutes. Follow with 1,000 IU (up to 1,500 IU)/kg/hr for 12 to 24 hours. See Maternal/Child.

DILUTION

All uses except cannula occlusion:

Each vial (250,000, 600,000, 750,000, or 1,500,000 IU) must be diluted with 5 mL of NS (preferred) or D5W. Add diluent slowly, direct to sides of vial, and roll and tilt gently. Do not shake. Further slowly dilute each vial to a total volume of 45 mL (preferred). May be diluted to a maximum of 500 mL in 45-mL increments. Discard solution with large amounts of flocculation or any solution remaining after 24 hours.

Arteriovenous cannula occlusion:

Each vial (250,000 IU) must be diluted with 2 mL NS. Use care in dilution as above.

Filters:

Can be infused through a 0.8-micron or larger pore filter.

Storage:

Refrigerate after initial dilution. Discard after 24 hours.

COMPATIBILITY

Manufacturer states, “Do not add other medications to the container of streptokinase.” Another source recommends not administering other medications through the same IV line.

RATE OF ADMINISTRATION

Volumetric or syringe infusion pump required. Reconstituted streptokinase will alter drop size and affect correct dosage with drop size mechanisms.

IV injection for coronary artery thrombi:

1.5 million IU evenly distributed over 60 minutes.

Coronary artery thrombi:

Bolus dose over 15 to 30 seconds via coronary catheter placed by Judkins or Sones technique directly to thrombosed site verified by selective coronary angiography. Follow with 2,000 IU/min for 60 minutes.

Deep vein thrombosis, pulmonary arterial embolism, arterial thrombi:

Loading dose: A single dose equally distributed over 25 to 30 minutes.
Maintenance dose: 100,000 IU or more as ordered equally distributed every hour for 24 to 72 hours. Dissolution of arterial thrombi may occur in 24 hours or less; deep vein thrombi may take up to 72 hours.

Arteriovenous cannula occlusion:

A single dose slowly (do not force) into each occluded limb of cannula. Clamp for 2 hours, then aspirate contents, flush with saline, and reconnect.

ACTIONS

An enzyme prepared from filtrates of beta-hemolytic streptococci. It combines with plasminogen and converts it to plasmin, which degrades fibrin clots, fibrinogen, and other plasma proteins. This activation takes place within a thrombus as well as on the surface. Onset of action is prompt and may last up to 12 to 24 hours. End products of this activity possess an anticoagulant effect. Bleeding may be very difficult to control.

INDICATIONS AND USES

Lysis of coronary artery thrombi. AHA standards identify thrombolytic agents as Class I therapy in patients younger than 70 years of age with chest pain consistent with acute MI and at least 0.1 mV of ST segment elevation in at least two ECG leads. Use in all other patients based on age, accurate diagnosis, and time from onset of chest pain. ■ Lysis of acute massive pulmonary emboli if one or more lobes are involved or if hemodynamics are unstable. ■ Lysis of an equivalent amount of thrombi in other vessels (deep veins). ■ Lysis of acute arterial thrombi and arterial emboli. ■ Clearing of occluded arteriovenous cannulae as an alternative to surgical revision.

CONTRAINDICATIONS

Active internal bleeding, cerebrovascular accident within 2 months, intracranial or intraspinal surgery, intracranial neoplasm, hypersensitivity to streptokinase. ■ ***Not indicated for restoration of patency of intravenous catheters.***

PRECAUTIONS

Administered only in the hospital under the direction of a physician knowledgeable in its use and with appropriate emergency drugs (e.g., antihistamines, glucocorticoids) and diagnostic and laboratory facilities immediately available. ■ For coronary catheter procedure, diagnosis of acute myocardial infarction must be confirmed and the site of the coronary thrombosis confirmed with selective angiography. Concurrent heparin therapy may be required in this situation. ■ Diagnosis of pulmonary or other emboli should be confirmed. Best results obtained if started within 5 to 7 days of onset of pulmonary emboli, 3 to 4 days of onset of DVT, and 3 days of onset of arterial thrombi. Discontinue streptokinase if thrombin time or other lysis parameters are not above 1½ times normal in 4 hours. Excessive resistance may be present. ■ Use extreme caution in the presence of atrial fibrillation or mitral stenosis with atrial fibrillation; very high risk of stroke from dislodged emboli. ■ May cause severe hypersensitivity reactions. Prior sensitization to streptokinase increases the risk of allergic reaction in subsequent courses of treatment. Antigenic (promotes antibody formation); incidence of allergic reaction greater than with alteplase (tPA). Use of an alternate agent (e.g., alteplase) may be indicated if repeat thrombolytic therapy required. ■ Use extreme caution in the following situations: any surgical procedure, biopsy, lumbar puncture, thoracentesis, paracentesis, multiple cutdowns, or intra-arterial diagnostic procedures within 10 days; ulcerative wounds; recent trauma with possible internal injury; visceral malignancy; pregnancy and first 10 days postpartum; any lesion of GI or GU tract with a potential for bleeding (e.g., diverticulitis, ulcerative colitis); severe hypertension; acute or chronic hepatic or renal insufficiency; uncontrolled hypocoagulable state; chronic lung disease with cavitation; rheumatic valvular disease; subacute bacterial endocarditis; and any condition in which bleeding might be hazardous or difficult to manage because of location. ■ See Contraindications; not indicated for restoration of patency in IV catheters. May cause life-threatening hypotension, hypersensitivity reactions, apnea, and bleeding.

Monitor:

Establish a separate IV line for streptokinase. ■ Observe patient continuously. Obtain hematocrit, platelet count, activated PTT, thrombin time, PT, and CPK before therapy. ■ Diphenhydramine 50 mg IV prophylactically is recommended. ■ In 4 hours and during therapy, thrombin time or PT changes are monitored and will reflect effectiveness of treatment. Keep physician continuously informed. Request specific parameters for notifying physician after initial supervised injection. ■ Coronary thrombi may lyse in 1 hour; continue treatment to ensure complete lysis. ■ Monitor ECG and record strips with greatest ST segment elevation initially and every 15 minutes for at least 4 hours. ■ Monitor BP frequently. ■ When thrombin time is less than twice the normal control value, initiate heparin infusion to keep PTT at 60 seconds. Prompt, easy treatment of IV injection is a distinct advantage over catheter procedure. ■ Maintain strict bed rest and apply pressure dressings to any recently invaded site. ■ A greater alteration of hemostatic status than with heparin; use care in handling patient; avoid arterial puncture, venipuncture, and IM injection. Use extreme precautionary methods (use of radial artery, not femoral; extended pressure application of up to 30 minutes) if procedures mentioned above are absolutely necessary. Minor bleeding occurs often at streptokinase insertion sites. Do not reduce or stop streptokinase, because lytic activity will be increased and cause more bleeding. ■ Monitor for hypotension and arrhythmias during therapy; atrial and ventricular arrhythmias can occur. ■ Intensive follow-up therapy with continuous infusion of heparin (without a loading dose) is indicated in all situations to prevent recurrent thrombosis. Begin in about 3 to 4 hours of completion of streptokinase, when the thrombin time or aPTT is reduced to less than twice the normal control value. ■ Do not take BP in lower extremities; thrombi may be dislodged. ■ Attempt to clear arteriovenous cannulae occlusions with good syringe technique and heparinized saline before using streptokinase. Allow effect of heparin to diminish. Instruct patients to exhale and hold their breath any time the catheter is not connected to the IV tubing or syringe to prevent air from entering the open catheter and thus the circulatory system.

Patient Education:

Report any signs of hypersensitivity reaction promptly (e.g., itching, rash, shortness of breath). ■ Compliance with all measures to minimize bleeding (e.g., strict bed rest) is very important. ■ Avoid use of razors, toothbrushes, and other sharp items. ■ Use caution while moving to avoid excessive bumping. ■ Report all episodes of bleeding and apply local pressure if indicated.

Maternal/Child:

Category C: use only if clearly needed. Safety for use in pregnancy, breast-feeding, or pediatric patients not established. ■ Use in pediatric patients based on anecdotal reports in patients from less than 1 month to 16 years of age.

Elderly:

See Indications and Precautions. ■ May have poorer prognosis following MI and pre-existing conditions that may increase risk of intracranial bleeding. Select patients carefully to maximize benefits.

DRUG/LAB INTERACTIONS

Risk of bleeding may be increased by **any medicine that affects blood clotting,** including anticoagulants (e.g., heparin, warfarin [Coumadin]); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs [e.g., ibuprofen (Advil, Motrin), naproxen (Aleve, Naprosyn)]); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel [Plavix], dipyridamole [Persantine], glycoprotein GPIIb/IIIa receptor antagonists [e.g., abciximab (ReoPro), eptifibatide (Integrilin), tirofiban (Aggrastat)], plicamycin [Mithracin], sulfinpyrazone [Anturane], valproic acid [Depacon]). Concurrent use not recommended with the exception of heparin and aspirin (in AMI) to reduce the risk of rethrombosis. If concurrent or subsequent use indicated (e.g., management of acute coronary syndrome, percutaneous coronary intervention), monitor PT and aPTT closely. ■ **Coagulation tests will be unreliable;** specific procedures can be used; notify the lab of streptokinase use.

SIDE EFFECTS

Hypersensitivity reactions, including anaphylaxis, are not uncommon with streptokinase. Arrhythmias, hypotension. Fever increase of 1° to 2° F is common. Bleeding can be life threatening.

ANTIDOTE

Notify physician of all side effects. Note even the smallest bleeding tendency. Therapy may need to be discontinued for serious blood loss and bleeding not controlled by local pressure. Whole blood, packed RBCs, cryoprecipitate, fresh frozen plasma, platelets, desmopressin, tranexamic acid, and aminocaproic acid may all be indicated. Do not use dextran. Topical preparations of aminocaproic acid may stop minor bleeding. Consider protamine if heparin has been used. Treat bradycardia with atropine, and treat reperfusion arrhythmias with lidocaine or procainamide; VT or VF may require cardioversion. If hypotension occurs, reduce rate promptly. If not resolved, vasopressors (e.g., dopamine), Trendelenburg position, and suitable plasma expanders (e.g., albumin, plasma protein fraction [Plasmanate], or hetastarch) may be indicated. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary.

STREPTOMYCIN SULFATE BBW

(strep-toe-**MY**-sin **SUL**-fayt)
Antibacterial (aminoglycoside)
Antituberculosis
pH 5 to 8

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

All IV Doses and Uses are Unlabeled.

Mycobacterium tuberculosis (unlabeled):

12 to 15 mg/kg daily. Calculation based on ideal body weight, not actual weight. 12 to 27 mg/kg has been used safely. Doses over 20 mg/kg are usually given every other day. Used in combination with isoniazid (INH), rifampin (Rifadin), and pyrazinamide. Maximum suggested total cumulative dose over course of therapy is 120 Gm.

Mycobacterium avium complex (unlabeled):

11 to 13 mg/kg daily. Part of a multiple drug regimen of three to five agents.

DOSE ADJUSTMENTS

Reduced dose required in renal impairment and/or nitrogen retention. ■ Reduce dose in patients over 60 years based on age, renal function, and eighth nerve impairment. ■ Elevated peak drug concentrations require a reduced dose. ■ See Drug/Lab Interactions.

DILUTION

Prepared solution equals 400 mg/mL. Further dilute total daily dose to a volume of 100 mL with D5W or D5NS.

Storage:

Refrigerate undiluted ampules. Diluted solution is stable for 24 hours at room temperature. According to the National Jewish Center guidelines, the current formulation from Pfizer is stable for up to 30 days after dilution if refrigerated.

COMPATIBILITY

Inactivated in solution with beta-lactam antibiotics (e.g., cephalosporins, penicillins) and vancomycin. Do not mix in the same solution. Appropriate spacing required because of physical **incompatibilities.** See Drug/Lab Interactions.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Total daily dose, properly diluted, as an infusion over 30 minutes. Slow rate to 60 minutes if any tingling or dizziness occurs during administration or if elevated peak drug concentrations occur.

ACTIONS

An aminoglycoside antibiotic with potential neuromuscular blocking action. Inhibits protein synthesis in bacterial cells. Bactericidal against specific gram-negative organisms and bacilli. Well distributed through all organ tissues except the brain (unless meninges inflamed). Peak serum levels of 25 to 50 mcg/mL occur promptly and gradually decrease to 12.5 to 25 mcg/mL over 5 to 6 hours. Usual half-life is 2.5 hours. Half-life is prolonged in infants, postpartum females, liver disease and ascites, spinal cord injury, cystic fibrosis, and the elderly. May be prolonged up to 100 hours in end-stage renal disease. Half-life is shorter in anemia, severe burns, and fever. Crosses the placental barrier. 30% to 90% excreted in urine within 24 hours.

INDICATIONS AND USES

All IV uses are unlabeled. Treatment of *Mycobacterium tuberculosis* when one or more of the following drugs (ethambutol [Myambutol], isoniazid [INH], rifampin [Rifadin], or pyrazinamide) is contraindicated because of toxicity, intolerance, or drug resistance. Increased rates of drug resistance and/or concomitant HIV infection are more common than in previous times. Usual four-drug regimen is either ethambutol or streptomycin with isoniazid, rifampin, and pyrazinamide. IV administration is especially useful in cachectic patients or those needing prolonged streptomycin therapy.

- *Mycobacterium avium* complex, a common infection in AIDS patients.

CONTRAINDICATIONS

Known streptomycin sensitivity. Known aminoglycoside sensitivity may be a contraindication due to cross-sensitivity.

PRECAUTIONS

Labeled for IM use only; probably due to impurities in early preparations. New formulations are being given IV safely; check your hospital's policy in case an informed consent or release is required. ■ Handle with care; may cause skin sensitivity reactions. ■ Used only when other, less hazardous agents are ineffective or contraindicated. ■ Adequate laboratory and audiometric testing facilities must be available. ■ Sensitivity studies necessary to determine susceptibility of causative organism to streptomycin. ■ Potentially nephrotoxic, ototoxic, and neurotoxic. Risk for neurotoxicity is sharply increased in patients with pre-existing renal damage or prerenal azotemia. Manifestations include disturbances of vestibular and cochlear function. Arachnoiditis, encephalopathy, optic nerve dysfunction, and peripheral neuritis may also occur. Partial or total irreversible deafness may continue to develop after streptomycin is discontinued. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with streptomycin. ■ May contain sulfites; use caution in patients with asthma. ■ For additional questions, consultations may be obtained from the Division of Infectious Disease at National Jewish Center.

Monitor:

Monitor serum BUN, creatinine, calcium, magnesium, potassium, and sodium before therapy and weekly. ■ Calcium, magnesium, potassium, and sodium levels may decline and require replacement. ■ Observe for any adverse effects including at the infusion site. ■ High serum levels increase risk of ototoxicity and neurotoxicity. Assess adequacy of dose and clearance of drug with serum streptomycin concentrations (2 to 6 hours after a timed dose) initially and every 2 to 4 weeks. Peak therapeutic levels are between 20 and 30 mcg/mL. Serum levels over 50 mcg/mL may be toxic. ■ Watch for decrease in urine output, rising BUN and SCr, and declining CrCl levels. A decrease in dose may be indicated; serum levels should not exceed 25 mcg/mL if any kidney damage is present. ■ Assess vestibular function toxicity weekly (Romberg test, past point, heel-to-toe, and lateral nystagmus). ■ Assess ototoxicity with audiograms every 2 to 4 weeks. ■ All of the above monitoring may be done more frequently if indicated. Permanently implanted central venous catheters allow treatment on an outpatient basis. Blood work may be done every 2 weeks and all other tests every 4 weeks when stable enough to be treated as an outpatient. ■ Maintain good hydration. Dehydration may increase risk of nephrotoxicity; monitor closely if vomiting, diarrhea, or other events that may cause dehydration occur. ■ Closely monitor patients with impaired renal function for nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity); nephrotoxicity may be reversible. ■ National Jewish Center uses chromatographic assay to determine streptomycin serum levels; concomitantly administered antibiotics do not have to be withheld when collecting samples for analysis. ■ Usual length of treatment for tuberculosis is 1 year. Discontinue streptomycin therapy whenever toxic symptoms appear, impending toxicity is feared, organisms become resistant, or full therapeutic effect is achieved. ■ In long-term therapy, alkalinization of urine may minimize renal irritation. ■ See Drug/Lab Interactions.

Patient Education:

Report promptly any changes in balance, dizziness, hearing loss, or weakness. ■ Consider effective birth control options. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category D: avoid pregnancy; has caused total, irreversible, bilateral deafness in infants whose mothers received streptomycin during pregnancy. ■ Discontinue breast-feeding. ■ Has caused CNS depression, including stupor, flaccidity, coma, and deep respiratory depression in very young infants.

Elderly:

Risk of toxicity increased; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **beta-lactam antibiotics** (e.g., cephalosporins, penicillins) **and vancomycin.** Synergism may be inconsistent; see Compatibility. ■ Concurrent or sequential use with any **other neurotoxic, ototoxic, or nephrotoxic agents** should be avoided. May have dangerous additive effects with **other aminoglycosides** (e.g., gentamicin, tobramycin), **diuretics** (e.g., furosemide [Lasix], mannitol), **beta-lactam antibiotics** (e.g., cephalosporins), **colistin** (Coly-Mycin S), **polymyxin B, vancomycin, cyclosporine, and many others.** ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, and tetracycline); bactericidal action may be affected. ■ **Magnesium sulfate** may reduce antibiotic activity of streptomycin. ■ **Anesthetics** (e.g., enflurane) **and neuromuscular blocking muscle relaxants** (e.g., atracurium [Tracrium], succinylcholine) are potentiated by aminoglycosides. Respiratory paralysis and ***apnea can occur.*** ■ Aminoglycosides are potentiated by **anticholinesterases** (e.g., edrophonium) **and antineoplastics** (e.g., nitrogen mustard, cisplatin). ■ See Side Effects.

SIDE EFFECTS

Occur more frequently with impaired renal function, higher doses, prolonged administration, dehydration, in the elderly, and in patients receiving other ototoxic or nephrotoxic drugs. Apnea, azotemia, CDAD, cochlear ototoxicity (hearing loss and deafness), eosinophilia, exfoliative dermatitis, facial paresthesias, fever, hemolytic anemia, hypersensitivity reactions (e.g., angioneurotic edema, anaphylaxis, itching, rash, urticaria), leukopenia, muscular weakness, neuromuscular blockade, pancytopenia, roaring in the ears, seizures, thrombocytopenia, tinnitus, vestibular ototoxicity (nausea and vomiting, vertigo). Least nephrotic of the aminoglycosides but nephrotoxicity does occur. Has caused severe chilling (rigors) with penicillins if spacing is not adequate.

ANTIDOTE

Notify the physician of all side effects. Discontinue streptomycin with any evidence of renal impairment, ototoxicity, or vestibular toxicity. Tinnitus, roaring noises, or a sense of fullness in the ears indicate a need for audiometric examination. Auditory changes are usually irreversible and bilateral and may be partial or total. Vestibular symptoms are reversible if detected early. A reduction in dose may be required or an alternate drug used. In overdose hemodialysis may be indicated. Monitor fluid balance, CrCl, and plasma levels carefully. Complexation with ticarcillin may be as effective as hemodialysis. Calcium salts or neostigmine may reverse neuromuscular blockade. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Resuscitate as necessary.

STREPTOZOCIN BBW

(strep-toe-**ZOH**-sin)
Zanosar
Antineoplastic (alkylating agent/nitrosurea)
pH 3.5 to 4.5

USUAL DOSE

Pretreatment:

Pretesting required; see Monitor. See Maternal/Child.

Streptozocin:

500 mg/M^2 for 5 consecutive days; see Monitor. Repeat every 6 weeks until maximum benefit or treatment-limiting toxicity observed. May also give 1,000 mg/M^2 weekly for 2 doses. May then increase up to 1,500 mg/M^2 to achieve therapeutic response if significant toxicity not observed. Overall cumulative dose to onset of response is 2,000 mg/M^2. Maximum response is usually achieved with 4,000 mg/M^2 total cumulative dose.

DOSE ADJUSTMENTS

Reduce dose in impaired renal function; see Precautions/Monitor. ■ Reduce dose or discontinue drug if mild proteinuria occurs. Lower-end initial doses may be appropriate in the elderly; consider the potential for decreased organ function and concomitant disease or drug therapy. ■ Can be used with other antineoplastic drugs in reduced doses to achieve tumor remission.

DILUTION

Specific techniques required; see Precautions. Each 1-Gm vial must be diluted with 9.5 mL NS or D5W (100 mg/mL). Usually further diluted in larger amounts (50 to 250 mL) of the same solutions.

Storage:

Store in refrigerator before and after dilution. Discard within 12 hours of dilution. Contains no preservatives. Protect from light.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose in minimum diluent given over 5 to 15 minutes is recommended. Increase injection time somewhat if additional diluent used or if indicated for patient comfort. Has been given as a continuous infusion over 5 days. Some side effects may be reduced, but CNS side effects (e.g., confusion, depression, lethargy) may be increased.

ACTIONS

An alkylating agent of the nitrosurea group with antitumor activity, cell cycle phase nonspecific. Has a diabetogenic (hyperglycemic) effect resulting from selective uptake into and toxicity to pancreatic islet beta cells. Disappears from the blood rapidly. Concentrates in the liver and kidneys. Excreted primarily in urine.

INDICATIONS AND USES

Suppress or retard neoplastic growth in metastatic pancreatic islet cell carcinoma. Use limited by renal toxicity to those with symptomatic or progressive metastatic disease.

Unlabeled uses:

Treatment of adrenocortical and colon cancers and Hodgkin lymphoma.

CONTRAINDICATIONS

Hypersensitivity to streptozocin. Severely impaired liver or renal function may be a contraindication.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be readily available. ■ Consider risk of known toxic effects versus benefit before initiating therapy. ■ Marked decrease in leukocyte and platelet counts has occurred and may be fatal. ■ Risk of nephrotoxicity may be reduced by decreasing renal and urinary concentration of streptozocin and its metabolites with adequate hydration. ■ Avoid concomitant use with other potential nephrotoxins (e.g., aminoglycosides [e.g., gentamicin], amphotericin B). ■ Liver dysfunction and diarrhea have been observed in some patients.

Monitor:

Renal toxicity is dose related, cumulative, and can be fatal. Monitor renal function before, weekly, and for 4 weeks after each course of therapy (serial urinalysis, BUN, plasma creatinine, serum electrolytes, CrCl). Reduce dose or discontinue drug if mild proteinuria occurs. Further deterioration of renal function may occur; see Precautions. ■ Determine absolute patency and quality of vein and adequate circulation of extremity. Local inflammation (e.g., burning, edema, erythema, tenderness), severe cellulitis, and/or necrosis may result from extravasation. If extravasation occurs, discontinue injection; use another vein. ■ Have IV dextrose available especially with the first dose. Sudden release of insulin may precipitate hypoglycemia. Monitor serum glucose at periodic intervals. ■ Monitor CBC and liver function tests weekly. ■ Nausea and vomiting have occurred in all patients and can be severe. Prophylactic administration of antiemetics recommended. ■ Observe for any signs of infection. Use of prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Maintain hydration; see Precautions. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See Drug/Lab Interactions.

Patient Education:

Avoid pregnancy; effective birth control recommended. ■ Report IV site burning or stinging promptly. ■ Use caution in tasks that require alertness, such as driving or using complex machinery. ■ See Appendix D.

Maternal/Child:

Category D: avoid pregnancy. Produces teratogenic effects in rats. Has mutagenic potential. ■ Discontinue breast-feeding.

Elderly:

Differences in response compared to younger adults not observed. Lower-end initial doses may be appropriate; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Concurrent use with **hepatotoxic or nephrotoxic medications and radiation therapy** may increase toxicity and could be fatal. ■ Toxicity may be additive when used in combination with **other cytotoxic drugs** (e.g., cyclophosphamide [Cytoxan], doxorubicin [Adriamycin, Doxil]). ■ May prolong the elimination half-life of **doxorubicin** and lead to severe bone marrow suppression. A reduced dose of doxorubicin may be indicated. ■ Concurrent use with **phenytoin** (Dilantin) may decrease therapeutic effects of streptozocin.

SIDE EFFECTS

Anemia, decreased platelet count (precipitous), diarrhea, elevated AST and LDH, hepatic toxicity (usually reversible), hypoalbuminemia, hypoglycemia, insulin shock, leukopenia (precipitous), nausea and vomiting (severe), proteinuria, thrombocytopenia.

Two cases of diabetes insipidus have been reported.

ANTIDOTE

Notify physician of all side effects. Nausea and vomiting, hematologic changes, and renal toxicity (proteinuria) may require dose reduction or discontinuation of the drug. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. For extravasation, elevate extremity, consider injection of long-acting dexamethasone (Decadron LA) throughout extravasated tissue. Use a 27- or 25-gauge needle. Apply warm, moist compresses.

SUCCINYLCHOLINE CHLORIDE BBW

(suck-sin-ill-**KOH**-leen **KLOR**-eyed)
Anectine, Quelicin, Quelicin PF
Neuromuscular blocking agent (depolarizing)
Anesthesia adjunct
pH 3 to 4.5

USUAL DOSE

A test dose of 0.1 mg/kg (approximately 5 to 10 mg in an adult) is sometimes used to test patient sensitivity and recovery time. After anesthesia is introduced, administer to a spontaneously breathing patient. Respiratory depression either occurs rarely or is transient in patients who metabolize succinylcholine normally. Paralysis develops in patients who are unable to metabolize the drug; recovery may take 30 to 60 minutes. See Precautions.

0.3 to 1.1 mg/kg of body weight initially for short-term muscle relaxation (average is 0.6 mg/kg). Should be administered after unconsciousness induced to reduce patient discomfort. If muscle relaxation must be sustained over a long period of time, maintain with intermittent IV injections of 0.04 to 0.07 mg/kg at appropriate intervals or with a continuous infusion of 0.5 to 10 mg/min (average is 2.5 to 4.3 mg/min). Monitoring with a peripheral nerve stimulator advisable to avoid overdose, especially with a continuous infusion. Highly individualized, depending on response and degree of relaxation required. 1 mg/kg of body weight is sufficient to cause respiratory paralysis. Never exceed 150 mg total dose.

Electroshock therapy (unlabeled):

10 to 30 mg 1 minute before shock.

PEDIATRIC DOSE

See Maternal/Child.

Infants and small children:

1 to 2 mg/kg (most sources say 2 mg/kg).

Older children and adolescents:

1 mg/kg.

To sustain muscle relaxation in all pediatric patients maintain with intermittent injections of 0.3 to 0.6 mg/kg/dose at 5- to 10-minute intervals. Monitoring with a peripheral nerve stimulator advisable. Continuous infusion not recommended; increased risk of malignant hyperpyrexia.

DOSE ADJUSTMENTS

Minimal doses with extreme care are required in patients with low plasma pseudocholinesterase (e.g., abnormal body temperatures, anemia, burns, cancer, collagen diseases, dehydration, exposure to neurotoxic insecticides, malnutrition, myxedema, patients with a recessive hereditary trait, pregnancy, severe liver disease or cirrhosis, and patients receiving antimalarials, antineoplastics, chlorpromazine [Thorazine], echothiophate iodide [Phospholine], irradiation, MAO inhibitors [e.g., selegiline (Eldepryl)], neostigmine, oral contraceptives, or pancuronium). Use a test dose of 5 to 10 mg or cautiously administer a 0.1% infusion. ■ Lower-end initial doses may be indicated in the elderly based on potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

May be given undiluted if short-term muscle relaxation is desired. For intermittent or continuous infusion during anesthesia add 1 Gm of succinylcholine to 500 mL or 1 L of D5W, D5NS, or NS. 1 mL of diluted solution delivers 2 mg (1 mg) of succinylcholine. For all other uses, 100 mg in 1 L delivers 0.1 mg succinylcholine. Use only freshly prepared solutions.

Storage:

Store in refrigerator 2° to 8° C (36° to 46° F) after dilution. Multidose vials stable at room temperature for up to 14 days. Powder for infusion may be stored at room temperature before preparation. Store with the cap and ferrule intact and in a manner that minimizes the possibility of selecting the wrong product.

COMPATIBILITY

Manufacturer states, “Acidic; should not be mixed with alkaline solutions having a pH greater than 8.5” (e.g., barbiturates [e.g., phenobarbital (Luminal)]).

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Too-rapid rate may cause profound bradycardia and rarely asystole. Incidence of bradycardia higher with a second dose.

IV injection:

Single initial dose over 30 seconds.

Intermittent or continuous infusion:

Variable, depending on individual response and muscle relaxation required. Use an infusion pump or microdrip (60 gtt/mL) for accuracy. Never exceed 10 mg/min.

ACTIONS

An ultra-short-acting depolarizing skeletal muscle relaxant. Causes paralysis by interfering with neural transmission at the myoneural junction. Onset of action is within 0.5 to 1 minute. Duration of peak effect is 4 to 6 minutes. Recovery begins in 8 to 10 minutes. Metabolized to succinic acid and choline. Only a small amount is excreted by the kidneys. Crosses placental barrier in small amounts.

INDICATIONS AND USES

Adjunct to general anesthesia to facilitate tracheal intubation and to provide skeletal muscle relaxation during surgery or mechanical ventilation.

Unlabeled uses:

Termination or prevention of convulsive episodes resulting from drug toxicity or electroshock therapy.

CONTRAINDICATIONS

Hypersensitivity to succinylcholine. ■ Personal or family history of malignant hyperthermia. ■ Skeletal muscle myopathies. ■ After the acute phase of injury following major burns, multiple trauma, extensive denervation of skeletal muscle, or upper motor neuron injury.

PRECAUTIONS

Treatment results in paralysis, which may lead to respiratory arrest and death. This progression may be more likely to occur in a patient for whom it is not intended. Confirm proper selection of intended product. ■ Primarily used by or under the direct observation of the anesthesiologist. Appropriate emergency drugs and equipment for monitoring the patient and responding to any medical emergency must be readily available. ■ Small doses of nondepolarizing muscle relaxants (e.g., atracurium [Tracrium]) will reduce severity of muscle fasciculations and incidence of myoglobinuria (occurs more frequently in pediatric patients) but may cause a prolonged mixed block. ■ Incidence of bradycardia increased with repeat dosing; more pronounced in pediatric patients. Pretreatment with anticholinergic agents (e.g., atropine) may reduce the occurrence of bradyarrhythmias. ■ May cause prolonged blockade with hypocalcemia, hypokalemia, and cardiovascular, hepatic, or pulmonary disorders. ■ May cause serious cardiac arrhythmias, including cardiac arrest in patients who are digitalized or on quinidine, as well as those with electrolyte imbalance, hyperkalemia, or severe trauma. Use extreme caution; see Contraindications. ■ Patients with pre-existing hyperkalemia, or those with spinal cord injuries, paralysis, or degenerative or dystrophic neuromuscular disease, may become severely hyperkalemic with succinylcholine; use caution. ■ Prolonged respiratory paralysis may occur in patients with low plasma pseudocholinesterase (see Dose Adjustments; decreased plasma cholinesterase activity potentiates this drug). ■ Muscle fasciculation may cause additional trauma in patients with fractures or muscle spasm. ■ Severe anaphylactic reactions have been reported with neuromuscular blocking agents; some have been fatal. Use caution in patients who have had an anaphylactic reaction to another neuromuscular blocking agent (depolarizing or nondepolarizing); cross-reactivity has occurred. ■ Rare occurrences of acute rhabdomyolysis with hyperkalemia followed by ventricular dysrhythmias, cardiac arrest, and death after administration to apparently healthy pediatric patients who were subsequently found to have undiagnosed skeletal muscle myopathy (e.g., Duchenne's muscular dystrophy) have been noted; see Monitor and Maternal/Child. Has also been reported in adolescents. ■ Has been associated with acute onset of malignant hyperthermia. ■ Patients with myasthenia gravis may be resistant to succinylcholine. ■ May increase intraocular pressure. ■ May cause a transient increase in intracranial pressure. ■ May convert to a nondepolarizing block during repeated or prolonged administration. Respiratory depression and apnea are common. Use a peripheral nerve stimulator to confirm diagnosis before treating with anticholinergic agents and atropine; see Antidote.

Monitor:

This drug may produce apnea. Controlled artificial ventilation must be available and under direct observation at all times. ■ Observe for early signs of malignant hyperthermic crisis (acidosis, jaw muscle spasm, lack of laryngeal relaxation, rigidity, and unresponsive tachycardia). Continuous monitoring of temperature and expired CO_2 is recommended as an aid to early recognition of malignant hyperthermia. ■ Continuous ECG monitoring recommended. Observe for peaked T waves; may be an early sign of skeletal muscle myopathy. Occurs more often in males under 8 years of age. ■ Monitor for increased intragastric pressure; avoid regurgitation and possible aspiration. ■ See Precautions and Drug/Lab Interactions.

Maternal/Child:

Use extreme caution in pregnancy. There is greater potential for prolonged apnea because of increased sensitivity to succinylcholine in pregnant women. If used during cesarean section, apnea and flaccidity may occur in the neonate, depending on mother's dose. ■ Use caution in breast-feeding. ■ Because there are no S/S to identify patients at risk for acute rhabdomyolysis, it is recommended that succinylcholine use in pediatric patients be reserved for emergency intubation or instances in which immediate securing of the airway is necessary (e.g., laryngospasm, difficult airway, full stomach), or for IM use when a suitable vein is inaccessible.

Elderly:

Lower-end initial doses may be indicated; see Dose Adjustments. ■ Response of older versus younger patients not documented. ■ Delay in onset time may be caused by slower circulation time in cardiovascular disease, old age, or edematous states; allow more time for drug to achieve maximum effect.

DRUG/LAB INTERACTIONS

Neuromuscular blocking action of succinylcholine may be enhanced by **aprotinin, certain nonpenicillin antibiotics, beta-adrenergic blockers, chloroquine, diethylether, desflurane, isoflurane, lidocaine, lithium carbonate, magnesium salts, metoclopramide, oxytocin, procainamide, promazine, quinine, terbutaline, and trimethaphan**. ■ The neuromuscular blocking effect of succinylcholine may be enhanced by **drugs that reduce plasma cholinesterase activity** (e.g., chronically administered oral contraceptives, glucocorticoids, certain monoamine oxidase inhibitors) or by **drugs that irreversibly inhibit plasma cholinesterase**. ■ Capable of innumerable other drug interactions. ■ See Dose Adjustments.

SIDE EFFECTS

Consist primarily of an extension of pharmacologic actions. Succinylcholine may cause profound muscle relaxation resulting in respiratory depression and apnea (may be prolonged). Hypersensitivity reactions, including anaphylaxis, may occur rarely. Other reported adverse reactions include arrhythmias (e.g., bradycardia, tachycardia), cardiac arrest, excessive salivation, hyperkalemia, hypertension, hypotension, increased intraocular pressure, jaw rigidity, malignant hyperthermia, muscle fasciculation, postoperative muscle pain, rash, and rhabdomyolysis with possible myoglobinuric acute renal failure.

ANTIDOTE

Discontinue drug with onset of any major side effect. An anesthesiologist should be present. Controlled artificial ventilation must be continuous. Endotracheal intubation or tracheostomy is considered prophylactic if necessary for adequate respiratory exchange. Confirm diagnosis of phase II block by using a peripheral nerve stimulator; presence of muscle twitch must also have returned for at least 20 minutes. Both of these are necessary before reversal with anticholinesterase drugs (e.g., neostigmine) is attempted. Whole blood transfusion may restore absent cholinesterase activity and stimulate voluntary respiration in unresponsive cases. Atropine should help to control bradycardia. Treat malignant hyperthermic crisis symptomatically with cooling measures, restoration of electrolyte balance, IV fluids, and maintenance of urinary output. Sodium bicarbonate may be indicated. Dantrolene may be indicated. If cardiac arrest develops soon after succinylcholine administration in a healthy-appearing pediatric patient and is not believed to result from inadequate ventilation, oxygenation, or anesthetic overdose, immediate treatment for hyperkalemia should be instituted and include IV calcium, bicarbonate, and glucose with insulin concurrent with hyperventilation. Resuscitate as necessary.

SUGAMMADEX

(soo-**GAM**-ma-dex)
Bridion
Antidote

Selective relaxant binding agent
pH 7 to 8

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

A peripheral nerve stimulator should be used to determine when sugammadex should be initiated. Doses and timing of sugammadex administration should be based on monitoring for twitch responses and the extent of spontaneous recovery that has occurred. Before sugammadex administration and up until complete recovery of neuromuscular function, the patient should be well ventilated and a patent airway maintained. The recommended dose of sugammadex does not depend on the anesthetic regimen. Sugammadex can be used to reverse different levels of rocuronium-induced or vecuronium-induced neuromuscular blockade. Base dose on actual body weight.

For rocuronium and vecuronium:

Deep blockade: 4 mg/kg as a single IV bolus injection is recommended if spontaneous recovery of the twitch response has reached 1 to 2 posttetanic counts (PTCs) and there are no twitch responses to train-of-four (TOF) stimulation following neuromuscular blockade.

Moderate blockade:

2 mg/kg as a single IV bolus injection is recommended if spontaneous recovery has reached the reappearance of the second twitch (T_2) in response to TOF stimulation following neuromuscular blockade.

Immediate reversal of rocuronium only:

16 mg/kg as a single IV bolus injection is recommended if there is a clinical need to reverse neuromuscular blockade soon (approximately 3 minutes) after administration of a single dose of 1.2 mg/kg rocuronium. The efficacy of the 16 mg/kg dose following administration of vecuronium has not been studied.

DOSE ADJUSTMENTS

Individualize dose based on extent of spontaneous recovery at time of administration (rocuronium and vecuronium) and whether there is a need to rapidly reverse the neuromuscular blocking agent (rocuronium only). ■ Use of lower than recommended doses of sugammadex may lead to an increased risk of recurrence of neuromuscular blockade after initial reversal and is not recommended. ■ No dose adjustment is recommended in patients with mild to moderate renal impairment. Sugammadex is not recommended for use in patients with severe renal impairment. ■ No dose adjustment is recommended in patients with hepatic impairment, pulmonary complications, or cardiac disease (e.g., patients with ischemic heart disease, chronic heart failure, cardiac arrhythmias); see Precautions.

DILUTION

Available as a 100 mg/mL solution in a 2- or 5-mL single-dose vial. Solution is clear and colorless to slightly yellow-brown. Withdraw the calculated dose and inject into the IV line of a running infusion.

Filters:

No data available from the manufacturer.

Storage:

Store at CRT. Protect from light. If not protected from light, the vial must be used within 5 days.

COMPATIBILITY

May inject into the IV line of a running infusion with the following IV solutions: NS, D5W, D2.5/½NS, D5NS, Isolyte P in D5W, RL, and Ringer's solution. Flush line with a **compatible** solution (e.g., NS) before and after administration of sugammadex. Manufacturer states that sugammadex should not be administered with other products and that it is physically **incompatible** with ondansetron and verapamil.

RATE OF ADMINISTRATION

Administer intravenously as a single bolus injection over 10 seconds. May administer into an existing IV line. Flush line with a **compatible** solution before and after administration.

ACTIONS

A modified gamma-cyclodextrin. Sugammadex forms a complex with rocuronium and vecuronium, thereby reducing the amount of neuromuscular blocking agent (NMBA) available to bind to nicotinic cholinergic receptors in the neuromuscular junction. This results in the reversal of neuromuscular blockade induced by rocuronium and vecuronium. Neither sugammadex nor the complex of sugammadex and the NMBA binds to plasma proteins or erythrocytes. Sugammadex is not metabolized by the liver. No metabolites of sugammadex have been observed, and the only route of elimination observed is renal excretion of the unchanged product. Elimination half-life is about 2 hours.

INDICATIONS AND USES

Reversal of the neuromuscular blockade induced by rocuronium bromide and vecuronium bromide in adults undergoing surgery.

Limitations of use:

Sugammadex has not been studied for reversal following rocuronium or vecuronium administration in the ICU. ■ Sugammadex should not be used to reverse neuromuscular blockade induced by nonsteroidal NMBAs such as succinylcholine or benzylisoquinolinium compounds (e.g., atracurium, cisatracurium, mivacurium) or to reverse neuromuscular blockade induced by steroidal NMBAs other than rocuronium or vecuronium.

CONTRAINDICATIONS

Known hypersensitivity to sugammadex or any of its components.

PRECAUTIONS

For IV administration only. ■ Should be administered by a trained health care provider familiar with the use, actions, characteristics, and complications of NMBAs and neuromuscular block reversal agents. ■ Ventilatory support is mandatory for patients until adequate spontaneous respiration is restored and the ability to maintain a patent airway is ensured. Should neuromuscular blockade persist after sugammadex administration or recur following extubation, appropriate steps should be taken to provide adequate ventilation. ■ Hypersensitivity reactions have occurred in patients treated with sugammadex and can range from isolated skin reactions to serious systemic reactions (i.e., anaphylaxis, anaphylactic shock). ■ Cases of marked bradycardia, some of which have resulted in cardiac arrest, have been observed within minutes after the administration of sugammadex. ■ Delayed or minimal response to sugammadex has been reported in a small number of patients. ■ A minimum waiting time is necessary before administration of a steroidal neuromuscular blocking agent after the administration of sugammadex. ■ Has been associated with increases in aPTT and PT/INR of up to 25% for up to 1 hour. ■ Use with caution in patients with hepatic impairment accompanied by coagulopathy or severe edema. ■ Sugammadex is not recommended for use in patients with severe renal impairment, including those requiring dialysis. ■ See Drug/Lab Interactions.

Monitor:

Obtain baseline SCr. ■ Monitor the patient to ensure adequate ventilation and maintenance of a patent airway. Even if recovery from neuromuscular blockade is complete, other drugs used in the perioperative and postoperative period could depress respiratory function and necessitate the need for continued ventilator support. ■ A peripheral nerve stimulation device capable of delivering a train-of-four (TOF) stimulus is required. ■ TOF monitoring alone should not be relied on to determine the adequacy of neuromuscular blockade reversal as related to a patient's ability to adequately ventilate and maintain a patent airway following tracheal extubation. Satisfactory recovery should be determined through the assessment of skeletal muscle tone and respiratory measurements in addition to the response to the peripheral nerve stimulator. ■ Monitor for S/S of a hypersensitivity reaction. The most commonly reported hypersensitivity reactions were nausea, pruritus, and urticaria. Other reported hypersensitivity reactions have included bronchospasm, conjunctival edema, dermatologic reactions (erythema, flushing, rash, skin erupption), reduction in peak expiratory flow, and swelling of the pharynx, tongue, and/or uvula. ■ Monitor for hemodynamic changes during and after reversal of neuromuscular blockade; see Antidote. ■ Monitor coagulation parameters (e.g., aPTT, PT/INR) in patients with known coagulopathies, patients being treated with therapeutic anticoagulation, patients receiving thromboprophylaxis drugs other than heparin or LMWH, or patients receiving any thromboprophylaxis drugs and sugammadex at a dose of 16 mg/kg.

Patient Education:

May reduce the efficacy of hormonal contraceptives. Women of reproductive potential who are using hormonal contraceptives should use an additional, nonhormonal contraceptive (e.g., condom, spermicide) for 7 days following sugammadex administration.

Maternal/Child:

Use during pregnancy only if clearly needed. ■ Use caution during breast-feeding. ■ Safety and efficacy for use in pediatric patients have not been established.

Elderly:

Dose adjustment is not generally needed in elderly patients with normal organ function, but an extended monitoring period to ensure complete reversal may be warranted. Risk of adverse events may be greater in patients with renal impairment. May be useful to monitor renal function.

DRUG/LAB INTERACTIONS

Toremifene has a high binding affinity for sugammadex. May cause displacement of vecuronium and rocuronium from the complex with sugammadex, thereby decreasing the effectiveness of sugammadex. Monitor for recurrence of neuromuscular blockade. Risk of displacement will be highest in the time period equivalent to 3 times the half-life of sugammadex. ■ Sugammadex may bind to **progestogen**, thereby decreasing progestogen exposure and effectiveness. Patients using **hormonal forms of contraception** (oral and nonoral) who receive sugammadex must use an additional, nonhormonal contraceptive method or backup method of contraception for the next 7 days. ■ Administration of **medications that can potentiate neuromuscular blockade** in the postoperative period (e.g., aminoglycosides, magnesium, vancomycin) may increase the possibility of recurrence of neuromuscular blockade. Monitor patients closely for recurrence if these medications must be administered. ■ Sugammadex may interfere with the **serum progesterone assay**.

SIDE EFFECTS

The most common side effects are headache, hypotension, nausea, pain, and vomiting. Other side effects include abnormal QT interval, airway complication of anesthesia, anesthetic complication, anxiety, bradycardia, chills, cough, decreased red blood cell count, depression, dizziness, dry mouth, erythema, fever, flatulence, hypersensitivity reactions (including anaphylaxis), hypertension, hypocalcemia, hypoesthesia, increased blood creatine phosphokinase, insomnia, myalgia, procedural complications, pruritus, recurrence of prolonged neuromuscular blockade, restlessness, tachycardia, and wound hemorrhage.

Post-Marketing:

Bradycardia, cardiac arrest, cardiac arrhythmias, dyspnea, hypersensitivity reactions (including anaphylaxis), laryngospasm, pulmonary edema, respiratory arrest, and wheezing.

ANTIDOTE

Treat anaphylaxis immediately with oxygen, epinephrine, antihistamines, vasopressors, corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Treatment with an anticholinergic such as atropine should be administered if clinically significant bradycardia is observed. Sugammadex can be removed using hemodialysis with a high-flux filter but not a low-flux filter. Resuscitate as necessary.

SULFAMETHOXAZOLE AND TRIMETHOPRIM

(sul-fah-meh-**THOX**-ah-zohl and try-**METH**-oh-prim)
SMZ-TMP, TMP-SMZ
Antibacterial
Antiprotozoal
pH 9.5 to 10.5

USUAL DOSE

Pretreatment:

Baseline studies and adequate hydration indicated; see Monitor. See Maternal/Child.

Doses listed are based on the trimethoprim component of the drug. Maximum recommended dose is 960 mg trimethoprim and 4,800 mg sulfamethoxazole/24 hr (60 mL/24 hr).

Severe urinary tract infections and shigellosis in adults and pediatric patients over 2 months of age:

8 to 10 mg/kg/24 hr in equally divided doses every 6, 8, or 12 hours (2 to 2.5 mg/kg every 6 hours, 2.67 to 3.33 mg/kg every 8 hours, or 4 to 5 mg/kg every 12 hours). Administer for 14 days (urinary tract infections) or 5 days (shigellosis).

Pneumocystis jiroveci pneumonitis in adults and pediatric patients over 2 months of age:

15 to 20 mg/kg/24 hr in equally divided doses every 6 or 8 hours (3.75 to 5 mg/kg every 6 hours or 5 to 6.67 mg/kg every 8 hours) for up to 14 days.

DOSE ADJUSTMENTS

Reduce dose by one-half for CrCl between 15 and 30 mL/min. Use is not recommended in patients with a CrCl less than 15 mL/min. ■ Reduced dose may be indicated in the elderly. ■ See Monitor and Drug/Lab Interactions.

DILUTION

Each 5-mL ampule (16 mg trimethoprim/mL [80 mg/5 mL], 80 mg sulfamethoxazole/mL [400 mg/5 mL]) must be diluted in 125 mL D5W and given as an infusion. Reduce D5W to 75 mL for each 5-mL ampule if fluid restriction is required. Standard dilution must be used within 6 hours; fluid restriction dilution must be used within 2 hours. 5 mL may also be mixed in 100 mL of D5W and used within 4 hours. Available in 5-, 10-, and 30-mL vials. Concentration per mL same as 5-mL ampule. Discard if cloudiness or crystallization is present.

Storage:

Store at room temperature; do not refrigerate. 10-mL and 30-mL vials may be multiple-dose containers. After entry into a multiple-dose vial, the remaining contents must be used within 48 hours.

COMPATIBILITY

Manufacturer states, “Do not mix with other drugs or solutions.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose must be infused over 60 to 90 minutes. Avoid rapid infusion or bolus injection.

ACTIONS

A broad-spectrum antibacterial and antiprotozoal combination agent with bactericidal action effective against gram-positive and gram-negative organisms. Blocks sequential steps in the biosynthesis of nucleic acids and proteins essential to many bacteria. Combination contains 400 mg sulfamethoxazole (a sulfonamide antimicrobial) and 80 mg trimethoprim (a dihydrofolate reductase inhibitor antibacterial) per each 5 mL. Metabolized in the liver and excreted in urine as metabolites and unchanged drug. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

For use in adults and pediatric patients 2 months of age and older for the following indications: Treatment of severe or complicated urinary tract infections due to susceptible strains of designated organisms when oral therapy is not feasible and when the organism is not susceptible to single-agent antibacterials effective in the urinary tract (see prescribing information). ■ Treatment of *Pneumocystis jiroveci* pneumonia. ■ Treatment of enteritis caused by susceptible strains of *Shigella flexneri* and *Shigella sonnei*.

CONTRAINDICATIONS

Hypersensitivity to trimethoprim or sulfonamides. ■ History of drug-induced immune thrombocytopenia with the use of trimethoprim and/or sulfonamides. ■ Patients with documented megaloblastic anemia due to folate deficiency. ■ Marked hepatic damage. ■ Severe renal insufficiency when renal function status cannot be monitored. ■ Pediatric patients under 2 months of age. ■ Concomitant administration with dofetilide

(Tikosyn).

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, sulfamethoxazole/trimethoprim should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to sulfamethoxazole/trimethoprim. ■ Not for IM use. ■ Fatalities associated with the administration of sulfonamides have occurred due to severe reactions, including Stevens-Johnson syndrome, toxic epidermal necrolysis, fulminant hepatic necrosis, agranulocytosis, aplastic anemia, and other blood dyscrasias. Discontinue therapy at the first appearance of a skin rash or any sign of adverse reaction. A skin rash may be followed by more severe reactions such as those listed previously. ■ Hypersensitivity reactions of the respiratory tract have been reported with sulfonamide treatment. ■ Severe cases of thrombocytopenia that are fatal or life threatening have been reported and may be immune-mediated. ■ Avoid use in treatment of streptococcal pharyngitis. Studies show that patients with group A beta-hemolytic streptococcal tonsillopharyngitis who are treated with sulfamethoxazole/trimethoprim have a greater incidence of bacteriologic failure than do those treated with penicillin. Failure to eradicate the organism may predispose the patient to sequelae such as rheumatic fever. ■ Avoid use in patients with impaired liver or renal function, in patients with possible folate deficiency (e.g., elderly patients, patients with chronic alcohol use disorder, patients receiving anticonvulsant therapy, patients with malabsorption syndrome, and patients in malnutrition states), and in patients with severe allergies or bronchial asthma. Hematologic changes indicative of folic acid deficiency may occur in patients with pre-existing folic acid deficiency or kidney failure. These effects are reversible with folinic acid therapy. ■ Use caution in patients with glucose 6-phosphate dehydrogenase (G-6PD) deficiency. Hemolysis may occur and is often dose related. ■ Cases of hypoglycemia in nondiabetic patients has been reported and usually occurs after a few days of therapy. Patients with renal dysfunction, liver disease, or malnutrition, or patients receiving high doses of sulfamethoxazole/trimethoprim, are particularly at risk. ■ Avoid use in patients with porphyria or thyroid dysfunction. Can precipitate porphyria crisis and hypothyroidism. ■ Electrolyte abnormalities (including hyperkalemia and severe and symptomatic hyponatremia) can occur, particularly with higher doses. Patients with underlying disorders of potassium metabolism, patients with renal insufficiency, or patients who are taking drugs known to induce hyperkalemia may experience hyperkalemia at the lower recommended doses. ■ Some products contain bisulfites; use caution in patients with allergies. ■ Incidence of side effects markedly increased in AIDS patients. May not tolerate or respond to this drug. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with sulfamethoxazole/trimethoprim.

Monitor:

Maintain adequate hydration to prevent crystalluria and stone formation. Monitor fluid intake and urinary output. ■ Obtain baseline and periodic CBC with platelets. Monitor for any hematologic toxicity. Discontinue for any significant reduction in a blood-forming element. Thrombocytopenia usually resolves within a week after discontinuing sulfamethoxazole/trimethoprim. ■ Urinalysis and renal function tests are also indicated. ■ Monitor serum potassium, sodium, and glucose. ■ Monitor closely for any signs of adverse reactions. Clinical signs such as arthralgia, cough, fever, jaundice, pallor, purpura, rash, shortness of breath, or sore throat may be early indications of serious reactions. ■ Monitor for S/S of hypersensitivity reactions of the respiratory tract (e.g., cough, pulmonary infiltrates, shortness of breath). ■ If extravasation occurs, discontinue and restart at a new site. May cause phlebitis. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Maintain adequate hydration. ■ Report bruising or bleeding, fever, rash, or sore throat promptly. ■ Possible skin photosensitivity. Avoid unprotected exposure to sunlight. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

May cause fetal harm. Some epidemiologic studies suggest that exposure to sulfamethoxazole/trimethoprim during pregnancy may be associated with an increased risk of congenital malformations, particularly neural tube defects, cardiovascular malformations, urinary tract defects, oral clefts, and club foot. Benefits must outweigh risks. ■ May contain benzyl alcohol, which has been associated with a fatal “gasping syndrome” in neonates. ■ See Contraindications. ■ Discontinue breast-feeding because of the potential risk for bilirubin displacement and kernicterus in the breast-fed infant. ■ Contraindicated in pediatric patients under 2 years of age because of the potential risk of bilirubin displacement and kernicterus.

Elderly:

See Dose Adjustments. ■ Increased risk of severe side effects (e.g., bone marrow suppression, decrease in platelets with or without purpura, hyperkalemia, skin reactions), especially in impaired renal or liver function or with other drugs (e.g., diuretics).

DRUG/LAB INTERACTIONS

May enhance the nephrotoxicity of **cyclosporine**; avoid concurrent use. ■ May potentiate **warfarin**; monitor PT/INR. ■ May inhibit the hepatic metabolism of **phenytoin**; monitor phenytoin levels. ■ May potentiate the effects of **oral hypoglycemics that are metabolized by CYP2C8** (e.g., pioglitazone, repaglinide) **or CYP2C9** (e.g., glipizide and glyburide) **or are eliminated renally via OCT2** (e.g., metformin). Careful monitoring of blood glucose may be warranted. ■ Trimethoprim may increase serum concentrations of **dapsone**; monitor for toxic effects of dapsone (specifically methemoglobinemia). ■ Potential for additive myelotoxicity when coadministered with **zidovudine**; monitor for hematologic toxicity. ■ The sulfa component may displace **methotrexate** from its binding sites and competes with the renal transport of methotrexate, increasing free fraction of methotrexate and its potential for toxicity; avoid concurrent use. ■ May decrease effectiveness of **tricyclic antidepressants**. ■ Concurrent use with **leucovorin calcium** may cause treatment failure and increased mortality in HIV-infected patients being treated for *Pneumocystis jiroveci* pneumonia. ■ Serum levels of **digoxin** may be increased with concurrent use; monitor digoxin levels. ■ Increased sulfamethoxazole blood levels may occur in patients receiving **indomethacin**; avoid concurrent use. ■ Patients receiving **pyrimethamine** as malaria prophylaxis and sulfamethoxazole/trimethoprim concurrently may develop megaloblastic anemia; avoid concurrent use. ■ May form an insoluble precipitate in acid urine or cause crystalluria with **methenamine**; concurrent use not recommended. ■ May decrease clearance and increase serum concentrations of ***N-acetylprocainamide*** (NAPA) **and procainamide**, resulting in prolongation of the QT_c interval. Monitor for clinical and ECG signs of procainamide toxicity and/or procainamide plasma concentrations. ■ Trimethoprim may increase **dofetilide** plasma concentrations, increasing the risk for serious ventricular arrhythmias associated with QT interval prolongation, including torsades de pointes. Concurrent use is ***contraindicated***. ■ Concurrent use with **rifampin** will increase elimination, reduce serum concentrations, and shorten half-life of trimethoprim. ■ Concurrent use with **thiazide diuretics** in elderly patients may result in an increased incidence of thrombocytopenia with purpura; avoid concurrent use. ■ Concurrent use with **angiotensin-converting enzyme inhibitors** may increase the risk of hyperkalemia; avoid concurrent use. ■ Toxic delirium has been reported after concurrent use with **amantadine**; avoid concurrent use. ■ May interfere with **serum methotrexate assay and Jaffe assay for creatinine.** ■ See Precautions.

SIDE EFFECTS

The most common adverse effects are anorexia, nausea, rash, urticaria, and vomiting. Serious side effects include CDAD, electrolyte abnormalities, embryo-fetal toxicity, hypersensitivity and other fatal reactions, hypoglycemia, infusion reactions, risk associated with concurrent use of leucovorin, sulfite sensitivity, and thrombocytopenia. Other reported reactions include abdominal pain; agranulocytosis; allergic myocarditis; angioedema; apathy; aplastic anemia; arthralgia; aseptic meningitis; ataxia; chills; conjunctival and scleral injection; convulsions; cough; crystalluria; depression; diarrhea; diuresis; drug fever; elevation of BUN, serum creatinine, serum transaminase, and bilirubin; eosinophilia; erythema multiforme; exfoliative dermatitis; fatigue; glossitis; hallucinations; headache; hemolytic anemia; Henoch-Schönlein purpura; hepatitis (including cholestatic jaundice and hepatic necrosis); hyperkalemia; hyponatremia; hypoprothrombinemia; insomnia; interstitial nephritis; leukopenia; local reactions (pain and irritation); megaloblastic anemia; methemoglobinemia; myalgia; nervousness; neutropenia; pancreatitis; periarteritis nodosa; peripheral neuritis; photosensitivity; pruritus; pseudomembranous enterocolitis; pulmonary infiltrates; renal failure; rhabdomyolysis; serum sickness–like syndrome; shortness of breath; Stevens-Johnson syndrome; stomatitis; systemic lupus erythematosus; thrombophlebitis; tinnitus; toxic epidermal necrolysis; toxic nephrosis with oliguria and anuria; uveitis; vertigo; and weakness.

Post-Marketing:

Idiopathic thrombocytopenic purpura, QT prolongation resulting in ventricular tachycardia and torsades de pointes, thrombotic thrombocytopenia purpura.

ANTIDOTE

Notify the physician of any side effect. Discontinue the drug at any sign of major toxicity or bone marrow suppression. Some sources recommend leucovorin calcium 5 to 15 mg daily for treatment of bone marrow suppression. Peritoneal dialysis is not effective in toxicity; hemodialysis may be moderately effective in reducing serum levels. Acidification of urine may increase excretion. Hematologic changes indicative of folic acid deficiency may be reversed with folinic acid therapy. Evaluate hyponatremia; appropriate correction is necessary in symptomatic patients to prevent life-threatening complications. Treat anaphylaxis with epinephrine, corticosteroids, antihistamines, and vasopressors. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated.

---

* This drug is on the Black Box Warning list; however, a BBW is not provided in the parenteral prescribing information.

USUAL DOSE

Pretreatment:

Verify pregnancy status; baseline studies indicated; see Monitor.

See Precautions. IV route used for patients unable to take oral medications; risk of anaphylaxis increased with IV administration. Transfer to oral therapy as soon as tolerated.

Whenever possible, administer the complete complement of vaccines before transplantation and treatment with tacrolimus.

For all indications:

Dose regimens vary among transplant centers and approved or investigational use (range 0.01 to 0.05 mg/kg/day). Begin no sooner than 6 hours after transplantation in liver and heart transplant patients. In kidney transplant patients, initial dose may be administered within 24 hours of transplantation but should be delayed until renal function has recovered. Adults usually receive doses at the lower end of the range. Pediatric patients may require doses at the upper end of the range. Individualized adjustment based on clinical assessment of rejection or patients' tolerance is imperative and may be required on a daily basis. Adjunctive adrenal corticosteroid therapy early posttransplant is recommended. Initiate oral tacrolimus therapy as soon as feasible. Oral doses vary with specific organ transplant and in adults and pediatric patients (see literature). Total dose in mg/kg/day is given in equally divided doses every 12 hours. Begin 8 to 12 hours after IV tacrolimus is discontinued. Lower doses may be sufficient for maintenance therapy.

Prophylaxis of organ rejection in heart transplant:

The recommended starting dose is 0.01 mg/kg/day as a continuous infusion. Used in combination with azathioprine or mycophenolate in addition to adrenal corticosteroids. Other immunosuppressants have also been used. See literature. See all comments and protocol under For All Indications above.

Prophylaxis of organ rejection in kidney transplant:

The recommended starting dose is 0.03 to 0.05 mg/kg/day as a continuous infusion. Used in combination with azathioprine or mycophenolate in addition to adrenal corticosteroids. See all comments and protocol under For All Indications above.

Prophylaxis of organ rejection in liver transplant:

The recommended starting dose is 0.03 to 0.05 mg/kg/day as a continuous infusion. Used in combination with adrenal corticosteroids. See all comments and protocol under For All Indications above.

PEDIATRIC DOSE

Has been used successfully in pediatric patients up to 16 years of age in liver transplants. See Usual Dose for mg/kg/day dose recommendations. Studies indicate that higher doses may be required to maintain blood trough concentrations similar to adults. Experience in pediatric heart and kidney transplant patients is limited but has been used. Consult literature. See Dilution and Maternal/Child.

DOSE ADJUSTMENTS

Dosing should be titrated based on clinical assessments of rejection and tolerability. ■ Use lower end of the dosing range initially for patients with impaired renal or hepatic function (pretransplant or posttransplant). Renal impairment does not affect clearance of tacrolimus, but tacrolimus may cause nephrotoxicity, requiring a reduction in dose. ■ Half-life is prolonged and clearance decreased in patients with severe hepatic impairment (Child-Pugh greater than or equal to 10). Higher levels resulting from decreased clearance can increase the risk of renal insufficiency. Dose reduction may be required. ■ In kidney transplant patients with postoperative oliguria, the initial dose of tacrolimus should be administered no sooner than 6 hours and within 24 hours of transplantation, but it may be delayed until renal function shows evidence of recovery. ■ Lower doses may be appropriate for maintenance. ■ Studies in kidney transplant patients indicate that African-American patients may require a higher dose to obtain trough concentrations comparable to those seen in White patients. ■ See Monitor and Drug/Lab Interactions.

DILUTION

Specific techniques required; see **Precautions**.

Available as a 5-mg/mL solution in a 1-mL ampule. A 24-hour dose must be diluted with an appropriate amount of NS or D5W. Desired concentration is between 4 and 20 mcg/mL. May leach phthalate from polyvinylchloride containers; mix in glass or polyethylene infusion bottles. Use PVC-free IV tubing in pediatric patients.

Storage:

Store between 20° and 25° C (68° and 77° F) before dilution. Discard diluted solution after 24 hours.

COMPATIBILITY

Manufacturer states, “Should not be mixed with solutions of pH 9 or greater.” See Dilution.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose properly diluted and equally distributed over 24 hours as a continuous infusion. Use of a metriset (60 gtt/min) or infusion pump suggested.

ACTIONS

A potent immunosuppressive agent. Prolongs survival of allogeneic heart, kidney, and liver transplants. Inhibition of T-lymphocyte activation and proliferation results in immunosuppression. Highly protein bound. Metabolized primarily by the P_{450} enzyme system (CYP3A). Half-life ranges from 32 to 55 hours. Primarily excreted in feces. Minimal excretion in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Prophylaxis of organ rejection in adult and pediatric patients receiving allogeneic heart, kidney, and liver transplants in conjunction with other immunosuppressants.

Unlabeled uses:

Treatment of autoimmune diseases (i.e., refractory rheumatoid arthritis). ■ Prevention and treatment of acute graft-versus-host disease.

CONTRAINDICATIONS

Hypersensitivity to tacrolimus or polyoxyl 60 hydrogenated castor oil.

PRECAUTIONS

Follow guidelines for handling hazardous agents. See Appendix A, p. 1308. ■ For IV use only. ■ Oral dosing preferred; begin as soon as feasible. Risk of anaphylaxis is increased by IV route versus oral route; use caution. ***Reserve for patients unable to take oral medication.*** ■ Usually administered in the hospital by or under the direction of a physician experienced in immunosuppressive therapy and management of organ transplant patients. ■ Adequate laboratory and supportive medical resources must be available. ■ Patients receiving immunosuppressants, including tacrolimus, are at increased risk of developing lymphomas and other malignancies (especially of skin). Risk appears to be related to intensity and duration of immunosuppression. ■ Has also been associated with a posttransplant lymphoproliferative disorder (PTLD), usually related to Epstein-Barr virus (EBV) infection. Risk of PTLD appears greatest in patients who are EBV-seronegative, which includes many young children. ■ Immunosuppressed patients are at increased risk for bacterial, viral, fungal, and protozoal infections, including opportunistic infections. May result in serious and fatal outcomes. ■ Opportunistic infections may include latent viral infections such as polyoma virus infections. Polyoma virus infections may result in polyoma virus–associated nephropathy (PVAN) and JC virus–associated progressive multifocal leukoencephalopathy (PML). PVAN is associated with serious outcomes, including deteriorating renal function and kidney graft loss. PML is a serious progressive neurologic disorder caused by infection of the CNS by the JC virus. It typically occurs in immunocompromised patients. PML is rare but may result in irreversible neurologic deterioration and death, and there is no known effective treatment. Hemiparesis, apathy, confusion, cognitive deficiencies, and ataxia are the most commonly observed clinical signs. ■ Patients receiving immunosuppression are at increased risk for developing cytomegalovirus (CMV), viremia, and CMV disease. ■ Tacrolimus can cause acute or chronic nephrotoxicity. Use caution in impaired renal function; increases in SCr may require dose reduction or use of an alternate immunosuppressant; see Dose Adjustments, Monitor, and Drug/Lab Interactions. ■ Use caution in severe hepatic dysfunction (mean Pugh score: greater than 10); clearance decreased; see Dose Adjustments. ■ Post–liver transplant patients experiencing hepatic impairment may be at increased risk of developing renal insufficiency related to elevated tacrolimus concentrations. ■ Can cause neurotoxicity, particularly at higher doses. The most severe neurotoxicities include posterior reversible encephalopathy syndrome (PRES), delirium, seizures, and coma; see Monitor. ■ Hyperkalemia has been reported. ■ Hypertension is a common adverse effect and may require hypertensive therapy; see Drug/Lab Interactions. ■ Concurrent use with sirolimus is not recommended in liver or heart transplant patients. Regimen is associated with an increased risk of wound healing complications, renal function impairment, and insulin-dependent, posttransplant diabetes mellitus in heart transplant patients; regimen is associated with excess mortality, graft loss, and hepatic artery thrombosis in liver transplant patients. The safety and efficacy of tacrolimus and sirolimus have not been established in kidney transplant patients. ■ New-onset diabetes mellitus has been reported in tacrolimus-treated heart, kidney, and liver transplant patients. May be reversible in some patients. African-American and Hispanic kidney transplant patients may be at an increased risk; see Monitor. ■ Myocardial hypertrophy has been reported in pediatric patients and adults, particularly in those with high tacrolimus trough concentrations. Reversible in most cases with dose reduction or discontinuation of tacrolimus. ■ May prolong the QT/QTc interval and cause torsades de pointes. Avoid use in patients with congenital long QT syndrome. Patients with CHF, bradyarrhythmias, or electrolyte abnormalities (e.g., hypokalemia, hypocalcemia, hypomagnesemia) and patients taking medicinal products that may lead to QT prolongation may be at increased risk; see Monitor and Drug/Lab Interactions. ■ Pure red cell aplasia (PRCA) has been reported. ■ See Drug/Lab Interactions.

Monitor:

Obtain baseline CBC, differential, platelets, electrolytes, fasting glucose, BUN, SCr, and liver function tests. Monitor regularly during therapy. ■ Contains a castor oil derivative; observe continuously for signs of a hypersensitivity reaction (e.g., acute respiratory distress syndrome [ARDS], dyspnea, pruritus, rash) for the first 30 minutes of the infusion and frequently thereafter. A source of oxygen and epinephrine must always be available. ■ Monitor Epstein-Barr virus (EBV) serology during treatment. ■

Observe for signs of infection (e.g., fever, sore throat, tiredness) or unusual bleeding or bruising. Adjust the immunosuppressive regimen to balance the risk of rejection with the risk of infection. ■ Monitor urine output and SCr carefully. Overt nephrotoxicity occurs more frequently early after transplant. Acute nephrotoxicity is characterized by increasing SCr, hyperkalemia, and/or a decrease in urine output and is usually reversible. Chronic nephrotoxicity is usually progressive and is associated with increased SCr, decreased life of kidney graft, and characteristic histologic changes on renal biopsy. Consider changing to another immunosuppressive therapy in patients with persistent elevations of SCr who are unresponsive to dose adjustments. ■ Monitor for S/S of neurotoxicity (e.g., changes in motor or sensory function, changes in mental status, coma, delirium, headache, paresthesias, tremors, seizures). ■ Monitor for S/S of PRES (e.g., altered mental status, headache, hypertension, seizures, and visual disturbances). Diagnosis may be confirmed by MRI. Stabilize BP and consider dose reduction. Symptoms have reversed when immunosuppression is reduced or discontinued. ■ Monitor for S/S of PML; apathy, ataxia, cognitive deficiencies, confusion, and hemiparesis are the most commonly observed clinical signs. Consultation with a neurologist may be indicated. ■ Tacrolimus whole blood trough concentrations in conjunction with other laboratory and clinical parameters are used to evaluate rejection, toxicity, need for dose adjustment, and patient compliance. Risk of toxicity (e.g., nephrotoxicity, neurotoxicity, posttransplant diabetes mellitus) is increased with higher trough concentrations. Whole blood median trough concentrations may vary considerably during the first week but then stabilize. Most patients are stable when trough whole blood concentrations are between 5 and 20 ng/mL depending on indication and length of time since the transplant. The trough concentrations described above and in the manufacturer's prescribing information pertain only to oral administration of tacrolimus. Monitoring tacrolimus concentrations during a continuous IV infusion of tacrolimus may have some utility; however, the observed concentrations will not represent exposures comparable to those estimated by the trough concentrations observed in patients on oral therapy. ■ Different methods are available for the assay of tacrolimus blood levels. Specific collection techniques and storage requirements are required. Contact the Clinical Laboratory for guidance. ■ Blood concentration monitoring is not a replacement for renal and liver function monitoring and tissue biopsies. Monitor all parameters to evaluate efficacy, toxicity, and the possibility of organ rejection. ■ Monitor BP; antihypertensives may be indicated; see Drug/Lab Interactions. ■ Monitor electrolyte concentrations. May cause hyperkalemia or hypomagnesemia; see Drug/Lab Interactions. ■ In patients with CHF, bradyarrhythmias, or electrolyte abnormalities (e.g., hypokalemia, hypocalcemia, hypomagnesemia) and in patients taking certain antiarrhythmics or other medicinal products that may lead to QT prolongation, consider obtaining an electrocardiogram and monitoring electrolytes periodically during treatment. ■ May cause hyperglycemia. Monitor carefully; treatment may be required. ■ Consider echocardiographic evaluation in patients who develop renal failure or clinical manifestations of ventricular dysfunction. Consider dose reduction or discontinuation of tacrolimus if myocardial hypertrophy is diagnosed. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Review manufacturer's medication guide. ■ Female and male patients of reproductive potential should discuss family planning options, including effective contraception, with a health care provider before starting treatment with tacrolimus. ■ Encourage female transplant patients who become pregnant and male patients who father a child and have been exposed to immunosuppressants, including tacrolimus, to enroll in the voluntary Transplantation Pregnancy Registry International. ■ May compromise male and female fertility. ■ Emphasize need for frequent routine lab work; compliance imperative. ■ Interacts with many medications. Discuss any changes in drug regimen (prescription or nonprescription) with doctor or pharmacist. ■ Promptly report any side effects (e.g., hypertension, nephrotoxicity, neurotoxicity, S/S of infection, heart failure). ■ Review S/S of diabetes mellitus. ■ Inform patient of increased risk of neoplasia, including malignant skin changes. Limit exposure to sunlight and ultraviolet light by wearing protective clothing and a broad-spectrum sunscreen with a high protection factor. Promptly report any skin changes. ■ See Appendix D, p. 1311.

Maternal/Child:

Data from post-marketing surveillance and an international pregnancy registry suggest that tacrolimus can cause fetal harm when administered to pregnant women. Infants exposed to tacrolimus in utero are at risk for prematurity, birth defects/congenital anomalies, low birth weight, and fetal distress. ■ Has been associated with hyperkalemia and renal dysfunction in the fetus. ■ May increase hyperglycemia in pregnant women with diabetes (including gestational diabetes); monitor maternal blood glucose levels regularly. ■ May exacerbate hypertension in pregnant women and increase pre-eclampsia. Monitor and control blood pressure. ■ Effects of tacrolimus on the breast-fed infant or on milk production have not been assessed. Use caution and consider risk versus benefit. ■ Manufacturer has a general statement that safety and effectiveness have been established for use in pediatric liver, kidney, and heart transplant patients. However, data are limited on use of the IV formulation in pediatric kidney and heart transplant patients. Consult literature for suggested dosage regimens. ■ Appears to be an increased risk for posttransplant lymphoproliferative disorder (PLPD) and primary Epstein-Barr virus infection in immunosuppressed pediatric patients.

Elderly:

Clinical trials did not include sufficient numbers of subjects 65 years of age and over to determine whether they respond differently from younger subjects. Clinical experience has not identified differences in response. In general, dose selection for an elderly patient should be cautious, starting at the lower end of the dosing range and taking into account age-related organ impairment and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

Used concurrently with **adrenocorticosteroids and azathioprine or mycophenolate (CellCept).** ■ Concomitant use of tacrolimus with **mycophenolic acid** (MPA) will increase MPA exposure more than exposure seen with concomitant use of MPA and cyclosporine. Monitor for MPA-associated toxicity and reduce MPA dose if needed. ■ ***Do not use simultaneously with cyclosporine.*** If a change of immunosuppressants is indicated (tacrolimus to cyclosporine or cyclosporine to tacrolimus), avoid additive nephrotoxicity by waiting for at least 24 hours before starting the alternate drug. If elevated blood concentrations are present, further extend the interval between the two drugs. ■ Concurrent use with **sirolimus** is not recommended; see Precautions. ■ Coadministration with **strong CYP3A4 inhibitors** (e.g., azole antifungal agents, boceprevir, clarithromycin, letermovir, ritonavir, telaprevir) **and strong inducers** (e.g., rifampin), **including those that prolong the QT interval** (e.g., azole antifungals, clarithromycin), is not recommended without adjustments in tacrolimus dosing and close monitoring of tacrolimus whole blood trough concentration and associated side effects. ■ Concurrent use with **other drugs that prolong the QT interval** may require dose adjustment and monitoring of the QT interval and trough concentrations. **Amiodarone** has been reported to increase tacrolimus whole blood concentration with or without concurrent QT prolongation. ■ Use extreme caution with **other nephrotoxic agents** (e.g., aminoglycosides, amphotericin B, cisplatin, ganciclovir, nucleotide reverse transcriptase inhibitors [e.g., tenofovir], and protease inhibitors [e.g., ritonavir, indinavir]); risk of nephrotoxicity increased. ■ Do not use **potassium-sparing diuretics** (e.g., spironolactone); increases risk of hyperkalemia. Other agents associated with hyperkalemia (e.g., **ACE inhibitors** and **angiotensin receptor blockers**) should be used with caution. ■ **Calcium channel blockers, chloramphenicol, cimetidine, clotrimazole, danazol, erythromycin, estradiol, fluconazole, herbal products containing schisandra sphenanthera extracts, lansoprazole, metoclopramide, metronidazole, omeprazole, protease inhibitors** (e.g., ritonavir, saquinavir), **and troleandomycin** may inhibit the P_{450} enzyme system and increase tacrolimus blood levels, increasing toxicity potential. Tacrolimus toxicity may also be increased if given concurrently with **nefazodone.** ■ Avoid concomitant use with **nelfinavir** unless benefits outweigh risks. ■ When initiating therapy with **posaconazole or voriconazole** in patients already receiving tacrolimus, decrease tacrolimus dose to one-third of the original dose. Adjust subsequent tacrolimus doses based on tacrolimus whole blood concentrations. ■ **Anticonvulsants, caspofungin, methylprednisone, rifamycins** (e.g., rifabutin, rifampin), **and St. John's wort** may induce the P_{450} enzyme system, decreasing effectiveness and leading to decreased tacrolimus blood levels and organ rejection. ■ Tacrolimus may increase serum concentrations of **phenytoin**. ■ **Grapefruit and grapefruit juice** may affect certain enzymes of the P_{450} system and should be avoided. ■ **Do not use live virus vaccines** in patients receiving tacrolimus. Inactivated vaccines noted to be safe for administration after transplantation may not be sufficiently immunogenic during treatment with tacrolimus.

SIDE EFFECTS

The most common adverse reactions were abdominal pain, abnormal renal function, anemia, bronchitis, CMV infection, constipation, diabetes mellitus, diarrhea, fever, headache, hyperglycemia, hyperkalemia, hyperlipidemia, hypertension, hypomagnesemia, infection, insomnia, leukopenia, nausea, paresthesia, pericardial effusion, peripheral edema, tremor, and urinary tract infection. Additional adverse reactions reported in the different studies are listed below.

Heart transplant:

Similar to above.

Kidney transplant:

Other commonly reported reactions included arthralgia, asthenia, back pain, chest pain, cough, dizziness, dyspepsia, dyspnea, graft dysfunction, hypokalemia, hypophosphatemia, nephrotoxicity, pain, pruritus, rash, and vomiting.

Liver transplant:

Abnormal LFTs, acidosis, anorexia, ascites, asthenia, atelectasis, back pain, bile duct disorder, dyspnea, EBV infection, gastroenteritis, GI hemorrhage, leukocytosis, nephrotoxicity, pain, peripheral edema, peritonitis, pleural effusion, pruritus, rash, sepsis, thrombocytopenia, vomiting.

Nephrotoxicity (abnormal renal function with increased SCr and BUN, oliguria) and neurotoxicity (delirium, headache, insomnia, paresthesia, tremor, seizures) may be dose limiting. Many other side effects have been reported; see Precautions and manufacturer’s prescribing information.

Post-Marketing:

Acute respiratory distress syndrome, agranulocytosis, cardiac arrhythmia, cerebral infarction, DIC, enterocolitis, febrile neutropenia, gastroesophageal reflux disease, GI perforation, hemolytic anemia, hepatotoxicity, interstitial lung disease, optic neuropathy, pain in extremity (including calcineurin-inhibitor–induced pain syndrome [CIPS]), posterior reversible encephalopathy syndrome (PRES), PRCA, primary graft dysfunction, progressive multifocal leukoencephalopathy (PML), and PVAN nephropathy are some of the many additional side effects reported.

ANTIDOTE

Notify the physician of all side effects. Most will be treated symptomatically. Tacrolimus dose may be decreased or discontinued or alternate immunosuppressive agents substituted. Nephrotoxicity, neurotoxicity, or hematopoietic depression may require temporary reduction of dose or discontinuation of therapy. Reduction in immunosuppression should be considered for patients who develop evidence of PVAN, PML, or CMV viremia and/or CMV disease. However, the risk that reduced immunosuppression represents to the functioning allograft must also be considered. If S/S of PRES occur, stabilize BP, and consider an immediate decrease of immunosuppression. Consider discontinuing tacrolimus if PRCA is diagnosed. Dialysis is not effective in overdose. Discontinue immediately if anaphylaxis occurs and treat with oxygen, epinephrine, corticosteroids, and/or antihistamines (e.g., diphenhydramine). Resuscitate as necessary.

TAGRAXOFUSP-erzs BBW

(tag-**RAX**-oh-fusp)
Elzonris
Antineoplastic

(CD123-directed cytotoxin)
pH 7.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Precautions and Monitor. Before initiating therapy, ensure that the patient has adequate cardiac function and serum albumin is 3.2 g/dL or greater.

Premedication:

Administer acetaminophen (or paracetamol), corticosteroid (e.g., 50 mg IV methylprednisolone or equivalent), H_1-histamine antagonist (e.g., diphenhydramine hydrochloride), and an H_2-histamine antagonist approximately 60 minutes before each tagraxofusp-erzs infusion.

Blastic plasmacytoid dendritic cell neoplasm (BPDCN) treatment in adults and pediatric patients 2 years and older:

Administer 12 mcg/kg IV once daily on Days 1 to 5 of a 21-day cycle. The dosing period may be extended for dose delays up to Day 10 of the cycle. Continue treatment until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

Monitor VS and check albumin, transaminases, and creatinine before preparing each dose. ■ See the following charts for dose modifications and guidelines.

Recommended Tagraxofusp-erzs Dose Modifications		
Parameter	**Severity Criteria**	**Dose Modification**
Serum albumin	Serum albumin ≤3.5 Gm/dL or reduced ≥0.5 Gm/dL from value measured before initiation of the current cycle	See CLS Management Guidelines (following chart).
Body weight	Body weight increase ≥1.5 kg over pretreatment weight on prior treatment day	See CLS Management Guidelines (following chart).
Aspartate aminotransferase (AST) or alanine aminotransferase (ALT)	ALT or AST increase >5 × ULN	Withhold tagraxofusp-erzs until transaminase elevations are ≤2.5 × ULN.
Serum creatinine	Serum creatinine >1.8 mg/dL (159 mcmol/L) or creatinine clearance ≤60 mL/min	Withhold tagraxofusp-erzs until serum creatinine resolves to ≤1.8 mg/dL (159 mcmol/L) or creatinine clearance ≥60 mL/min.
Systolic blood pressure	Systolic blood pressure ≥160 mm Hg or ≤80 mm Hg	Withhold tagraxofusp-erzs until systolic blood pressure is <160 mm Hg or >80 mm Hg.
Heart rate	Heart rate ≥130 beats/min or ≤40 beats/min	Withhold tagraxofusp-erzs until heart rate is <130 beats/min or >40 beats/min.
Body temperature	Body temperature ≥38° C (100.4° F)	Withhold tagraxofusp-erzs until body temperature is <38° C (100.4° F).
Hypersensitivity reactions	Mild or moderate	Withhold tagraxofusp-erzs until resolution of any mild or moderate hypersensitivity reaction. Resume tagraxofusp-erzs at the same infusion rate.
	Severe or life-threatening	Discontinue tagraxofusp-erzs permanently.

Capillary Leak Syndrome (CLS) Management Guidelines

Time of Presentation	CLS Sign/Symptom	Recommended Action	Tagraxofusp-erzs Dosing Management
Before first dose of tagraxofusp-erzs in Cycle 1	Serum albumin <3.2 Gm/dL	Administer tagraxofusp-erzs when serum albumin ≥3.2 Gm/dL.	
During tagraxofusp-erzs dosing	Serum albumin <3.5 Gm/dL	Administer 25 Gm IV albumin (q 12 hr or more frequently as practical) until serum albumin is ≥3.5 Gm/dL AND not more than 0.5 Gm/dL lower than the value measured before dosing initiation of the current cycle.	Interrupt tagraxofusp-erzs dosing until the relevant CLS S/S has resolved.[a]
	Serum albumin reduced by ≥0.5 Gm/dL from the albumin value measured before tagraxofusp-erzs dosing initiation of the current cycle		
	A predose body weight that is increased by ≥1.5 kg over the previous day's predose weight	Administer 25 Gm IV albumin (q 12 hr or more frequently as practical), and manage fluid status as indicated clinically (e.g., generally with IV fluids and vasopressors if hypotensive and with diuretics if normotensive or hypertensive) until body weight increase has resolved (i.e., the increase is no longer ≥1.5 kg greater than the previous day's predose weight).	
	Edema, fluid overload, and/or hypotension	Administer 25 Gm IV albumin (q 12 hr or more frequently as practical) until serum albumin is ≥3.5 Gm/dL. Administer 1 mg/kg/day of methylprednisolone (or equivalent) until resolution of CLS S/S or as indicated clinically. Aggressive management of fluid status and hypotension if present, which could include IV fluids and/or diuretics or other blood pressure management, until resolution of CLS S/S or as clinically indicated.	

[a] Tagraxofusp-erzs administration may resume in the same cycle if all CLS S/S have resolved and the patient did not require measures to treat hemodynamic instability. Tagraxofusp-erzs administration should be held for the remainder of the cycle if CLS S/S have not resolved or the patient required measures to treat hemodynamic instability (e.g., required administration of IV fluids and/or vasopressors to treat hypotension) (even if resolved), and tagraxofusp-erzs administration may resume in the next cycle only if all CLS S/S have resolved and the patient is hemodynamically stable.

DILUTION

Available as a single-dose vial containing 1,000 mcg/1 mL of tagraxofusp-erzs for dilution. Tagraxofusp-erzs is a preservative-free, sterile, clear, colorless solution that may contain a few white to translucent particles. Thaw vials at RT before preparation. Do not force thaw. Vial may be at RT for approximately 1 hour before dose preparation. A 2-step process is required for preparation of the final tagraxofusp-erzs dose.

Step 1:

Prepare 10 mL of 100 mcg/mL of tagraxofusp-erzs: (1) Using a sterile 10-mL syringe, transfer 9 mL of NS to an empty sterile 10-mL vial. (2) Gently swirl tagraxofusp-erzs vial to mix contents. Withdraw 1 mL of thawed tagraxofusp-erzs from the product vial using a sterile 1-mL syringe. (3) Transfer the 1 mL of tagraxofusp-erzs into the 10-mL vial containing NS. Gently invert the vial at least 3 times to mix. ***Do not shake vigorously***. Following dilution, the final concentration of tagraxofusp-erzs is 100 mcg/mL.

Step 2:

Prepare the tagraxofusp-erzs infusion set: (1) Calculate the required volume of diluted tagraxofusp-erzs (100 mcg/mL) according to patient's weight. (2) Draw up the required volume into a new syringe (if more than 10 mL of diluted tagraxofusp-erzs [100 mcg/mL] is required for the calculated patient dose, repeat step 1 with a second vial of tagraxofusp-erzs). Label the tagraxofusp-erzs syringe. (3) Prepare a separate syringe with at least 3 mL of NS to be used to flush the administration set once tagraxofusp-erzs dose is delivered. Label the flush syringe. (4) Connect the saline flush syringe to one arm of the Y-connector and ensure the clamp is closed. (5) Connect the product syringe to the other arm of the Y-connector and ensure the clamp is closed. (6) Connect the terminal end of the Y-connector to the microbore tubing. (7) Remove the cap from the supply side of the 0.2-micron filter and attach it to the terminal end of the microbore tubing. (8) Unclamp the arm of the Y-connector connected to the saline flush syringe. Prime the Y-connector up to the intersection (do not prime the full infusion set with saline). Reclamp the Y-connector line on the saline flush arm. (9) Remove the cap on the terminal end of the 0.2-micron filter and set aside. Unclamp the arm of the Y-connector connected to the product syringe and prime the entire infusion set, including the filter. Recap the filter, and reclamp the Y-connector line on the product side. The infusion is now ready for delivery of dose.

Filters:

Use of an in-line, 0.2-micron polyethersulfone (PES) filter is required.

Storage:

Before dilution: Store in freezer between −25° and −15° C (−13° and 5° F) in original package to protect from light. Thaw vials at RT before preparation. Thawed vials may be held at RT for approximately 1 hour before dose preparation. Do not refreeze vial once thawed. Do not use beyond expiration date. ***After dilution:*** Administer tagraxofusp-erzs within 4 hours. The prepared dose should remain at RT during the 4-hour window. Do not reuse excess tagraxofusp-erzs. Discard any excess material immediately following infusion.

COMPATIBILITY

Manufacturer indicates compatibility at Y-site with NS.

RATE OF ADMINISTRATION

Ensure venous access and maintain with NS. Use of an in-line, 0.2-micron polyethersulfone (PES) filter is required. Administer a single dose over 15 minutes via infusion syringe pump. The total infusion time will be controlled using a syringe pump to deliver the entire dose and the saline flush over 15 minutes. Insert the tagraxofusp-erzs syringe into the syringe pump, open the clamp on the tagraxofusp-erzs side of the Y-connector, and deliver the prepared dose. Once the tagraxofusp-erzs syringe has been emptied, remove it from the pump and place the saline flush syringe in the syringe pump. Ensure complete delivery of therapy by opening the clamp on the saline flush side of the Y-connector and resuming infusion via the syringe pump at the pre-specified flow.

ACTIONS

Tagraxofusp-erzs is a CD123-directed cytotoxin composed of recombinant human interleukin-3 (IL-3) and truncated diphtheria toxin (DT) fusion protein that inhibits protein synthesis and causes cell death in CD123-expressing cells. The mean terminal half-life is 0.7 hours.

INDICATIONS AND USES

Treatment of blastic plasmacytoid dendritic cell neoplasm (BPDCN) in adults and pediatric patients 2 years and older.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Administer in facilities equipped to monitor the patient and respond to any medical emergency. ■ Administer Cycle 1 of tagraxofusp-erzs in the inpatient setting with patient observation through at least 24 hours after the last infusion. ■ Administer subsequent cycles of tagraxofusp-erzs in the inpatient setting or in a suitable outpatient ambulatory care setting that is equipped with appropriate monitoring for patients with hematopoietic malignancies undergoing treatment. ■ Capillary leak syndrome (CLS), which may be life-threatening or fatal, can occur. ■ Tagraxofusp-erzs can cause severe hypersensitivity reactions. ■ Treatment with tagraxofusp-erzs is associated with elevations in liver enzymes. ■ As with all therapeutic proteins, there is a risk of immunogenicity.

Monitor:

Monitor vital signs and check albumin, transaminases, and creatinine before preparing each dose; see Dose Adjustments. ■ Before initiating therapy, ensure that the patient has adequate cardiac function and serum albumin is 3.2 Gm/dL or greater. ■ During treatment, monitor serum albumin levels before each dose initiation and as indicated clinically thereafter. ■ Monitor for S/S of CLS (weight gain, new-onset or worsening edema [including pulmonary edema], hypotension, or hemodynamic instability) and take actions as recommended; see Dose Adjustments. ■ Monitor for hypersensitivity reactions (e.g., pruritus, rash, stomatitis, and wheezing) during treatment. ■ Observe patients for a minimum of 4 hours after each infusion. ■ See Precautions and Antidote.

Patient Education:

Verify pregnancy status of females of reproductive potential before initiating therapy. ■ Avoid pregnancy. Advise females to use acceptable contraceptive methods during tagraxofusp-erzs treatment and for at least 1 week after the last dose. ■ Contact health care professional for any hypotension, new or worsening edema, shortness of breath, and/or weight gain after infusion. Weigh self daily. ■ Promptly report S/S of hypersensitivity reaction (e.g., flushing, rash, swelling of the face, and wheezing). ■ Promptly report anorexia, fatigue, and right upper abdominal discomfort.

Maternal/Child:

Avoid pregnancy. Based on its mechanism of action, tagraxofusp-erzs can cause fetal harm. ■ Do not breast-feed during treatment and for 1 week after the last dose. ■ The safety and effectiveness of tagraxofusp-erzs for treatment of BPDCN have been established in pediatric patients 2 years of age and older (no data for pediatric patients under 2 years of age).

Elderly:

Older patients experienced a higher incidence of altered mental status (including confusional state, delirium, dementia, encephalopathy, and mental status change) than younger patients.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed.

SIDE EFFECTS

The most common side effects are CLS, fatigue, fever, nausea, peripheral edema, and weight gain. Other side effects included anxiety, back pain, chills, confusional state, constipation, cough, decreased appetite, diarrhea, dizziness, dyspnea, epistaxis, febrile neutropenia, headache, hematuria, hypertension, hypotension, insomnia, oropharyngeal pain, pain in extremity, petechiae, pruritus, tachycardia, vomiting. The most common laboratory abnormalities are decreases in albumin, calcium, hemoglobin, platelets and sodium, and increases in ALT, AST, and glucose. Other laboratory abnormalities included decreases in glucose, magnesium, neutrophils, phosphate, potassium, and increases in alkaline phosphate, creatinine, bilirubin, magnesium, potassium, and sodium.

ANTIDOTE

Keep physician informed of all side effects. If hypersensitivity reactions occur, interrupt infusion and treat as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate), and pressor amines (e.g., dopamine). See Dose Adjustments for management of adverse reactions and CLS.

TALIGLUCERASE ALFA

(tal-e-**GLUE**-sir-ace **AL**-fa)
Elelyso
Enzyme replenisher
(glucocerebrosidase)
pH 6

USUAL DOSE

Pretreatment:

See Monitor.

Treatment-naïve adults and pediatric patients 4 years of age and older:

60 units/kg of body weight administered once every 2 weeks as a 60- to 120-minute IV infusion.

Patients switching from imiglucerase:

Patients currently being treated with imiglucerase for Type 1 Gaucher disease can be switched to taliglucerase alfa. Patients on a stable dose of imiglucerase may transfer to the same unit/kg dose of taliglucerase alfa. Administer dose every other week as a 60- to 120-minute IV infusion.

DOSE ADJUSTMENTS

Patients switching from imiglucerase:

Dose may increase or decrease based on achievement of each patient’s therapeutic goals. Optimal goal is to establish the lowest dose that is effective in maintaining control of the disease and preventing a recurrence of symptoms for each patient.

DILUTION

Available as a lyophilized powder in 200-unit vials. Determine the number of vials required using the following calculations:

Weight in kg × Dose/kg desired ÷ 200 (units/vial) = # of vials required

A 60-kg man requiring 60 units/kg would require 3,600 units. The number of vials required would be 18. If necessary, round up to the next whole vial. After patient is weighed and appropriate dose is calculated, remove sufficient vials from refrigerator. Do not leave vials at RT for longer than 24 hours before reconstitution.

Each 200-unit vial must be reconstituted with 5.1 mL of SWFI to yield a reconstituted product with a concentration of 40 units/mL and an extractable volume of 5 mL. Gently swirl to mix the solution. ***Do not shake.*** Withdraw exactly 5 mL (40 units/mL) from each 200-unit vial. A total dose must be further diluted with NS to a total volume of 100 to 200 mL. For ***pediatric patients***, a final volume of 100 to 120 mL should be used. For ***adult patients***, a final volume of 130 to 150 mL may be used. However, if the volume of the reconstituted product alone is equal to or greater than 130 to 150 mL, then the final volume should not exceed 200 mL. Mix gently; ***do not shake.*** Do not use if discolored or opaque or if particulate matter is present. After dilution, slight flocculation (thin translucent fibers) may occur.

Filters:

Should be administered through an in-line, low–protein-binding, 0.2-micron filter.

Storage:

Before use, refrigerate at 2° to 8° C (36° to 46° F). Protect from light. Do not freeze. Do not use after expiration date on bottle. Contains no preservative. Following reconstitution, immediate use is preferred; however, reconstituted and/or diluted vials may be refrigerated for up to 24 hours at 2° to 8° C (36° to 46° F) protected from light. Reconstituted vials are stable for up to 4 hours at 20° to 25° C (68° to 77° F) without protection from light. Store reconstituted and/or diluted product for no more than 24 hours protected from light. Do not freeze, and discard any unused product.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Use of an infusion set with an in-line, low–protein-binding, 0.2-micron filter is required. Use of an infusion pump is helpful. Flush the IV line with NS at the end of the infusion to ensure that the total dose is received. Administer as an infusion over 60 to 120 minutes as outlined in the following paragraphs. A reduction in the rate of infusion may be helpful in the event of side effects or infusion reactions.

Pediatric patients:

Begin with a rate of 1 mL/min. If the patient tolerates the initial infusion rate, it may be increased to 2 mL/min. Total time of the infusion should be no less than 1 hour.

Adult patients:

Begin with a rate of 1.2 mL/min. If the patient tolerates the initial infusion rate, it may be increased to 2.2 mL/min. Total time of the infusion should be no less than 1 hour.

ACTIONS

A hydrolytic lysosomal glucocerebroside-specific enzyme. It is produced by recombinant DNA technology using plant cell culture (carrot). An active form of the lysosomal enzyme β-glucocerebrosidase. It catalyzes the hydrolysis of glucocerebroside to glucose and ceramide, reducing the amount of accumulated glucocerebroside normally seen in patients with Gaucher disease. In clinical trials, spleen and liver size were reduced, and anemia and thrombocytopenia were improved. Median terminal half-life was 32.5 minutes in pediatric patients and 28.7 minutes in adult patients. No significant accumulation was noted with repeated dosing.

INDICATIONS AND USES

Treatment of patients with a confirmed diagnosis of Type 1 Gaucher disease.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Should be used under the direction of a physician knowledgeable in the management of Gaucher disease and administered in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, have occurred; see Monitor and Antidote. ■ A therapeutic protein product, patients have developed IgG antidrug antibodies (ADA) to taliglucerase alfa. The relationship between ADA and hypersensitivity reactions is not fully understood. Monitoring for ADA to taliglucerase alfa may be useful in ADA-positive patients or in patients who have experienced hypersensitivity reactions to taliglucerase alfa. Neutralizing antibodies have also been detected in some patients receiving taliglucerase alfa. Clinical relevance as it relates to therapeutic effect is unclear.

Monitor:

Obtain weight before each dose (used to calculate dose). ■ Monitor vital signs. ■ Observe patient during and after the infusion for S/S of a hypersensitivity reaction. In clinical trials, serious hypersensitivity reactions, including anaphylaxis, occurred during the infusion. S/S included chest tightness, dizziness, flushing, hypotension, nausea, urticaria, vomiting, and wheezing. Other hypersensitivity reactions occurred up to 3 hours after the start of the infusion and included angioedema, chest tightness, cough, erythema, flushing, nausea, pruritus, rash, throat irritation, and vomiting. Discontinue the infusion immediately if anaphylaxis occurs; consider the risk versus benefit of readministering taliglucerase in patients who have experienced a severe reaction. Caution should be exercised upon rechallenge. ■ Decreasing the infusion rate, temporarily stopping the infusion, and/or administering antihistamines, antipyretics, and/or corticosteroids is recommended. Pretreatment with antihistamines and/or corticosteroids may prevent subsequent reactions in these patients. ■ Observe patient closely for signs of improvement (e.g., improvement in hemoglobin and platelet counts, reduction in size of liver and/or spleen).

Patient Education:

Enzyme replacement therapy is required for life. ■ Promptly report S/S of a hypersensitivity or infusion reaction (e.g., chills, dizziness, fatigue, fever, headache, itching, nausea, rash, shortness of breath, wheezing). Reactions may occur during or after infusion. ■ Pretreatment with antihistamines or corticosteroids may be used to prevent reactions.

Maternal/Child:

Consider risk versus benefit. Women with Type 1 Gaucher disease have an increased risk of spontaneous abortion if disease symptoms are not treated and controlled before conception and during pregnancy. Pregnancy can exacerbate existing Type 1 Gaucher disease symptoms, and Type 1 Gaucher disease manifestations may lead to adverse pregnancy outcomes. ■ Safety for use during breast-feeding not established. Not known whether taliglucerase alfa is secreted in breast milk. The effects on the breast-fed infant or on milk production are also unknown. ■ Safety and effectiveness for use in pediatric patients under 4 years of age not established. Pediatric patients experienced a higher frequency of vomiting than adult patients. Frequencies of other adverse reactions were similar between adult and pediatric patients.

Elderly:

Numbers in clinical studies insufficient to determine whether the elderly respond differently than do younger adults.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

The most commonly reported adverse reactions in clinical trials were abdominal pain, arthralgia, dizziness, extremity pain, fatigue, flushing, headache, nausea, pruritus, rash, urticaria, and vomiting. Back pain, diarrhea, and hypersensitivity reactions have also been reported.

Post-Marketing:

Anaphylaxis.

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. Based on the severity of the reaction, temporarily slow, interrupt, or discontinue infusion for clinical evidence of a hypersensitivity reaction. Patients have successfully continued therapy after mild hypersensitivity reactions with a reduction in rate of administration and/or treatment or pretreatment with antipyretics, antihistamines (e.g., diphenhydramine), and/or corticosteroids (e.g., dexamethasone). Discontinue infusion immediately for anaphylaxis and treat with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

TEDIZOLID PHOSPHATE

(te-**DIZ**-oh-lid **FOS**-fayt)
Sivextro
Antibacterial (oxazolidinone)

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Tedizolid:

200 mg once daily for 6 days as an infusion over 1 hour. Alternately, may be given orally (with or without food).

DOSE ADJUSTMENTS

No dose adjustment necessary when changing from IV to oral doses. ■ If a dose is missed or delayed, it should be administered as soon as possible any time up to 8 hours before the next scheduled dose. If less than 8 hours remain before the next dose, wait until the next scheduled dose. ■ No dose adjustments indicated based on age, gender, weight, race, or any degree of hepatic or renal impairment.

DILUTION

Available in single-use vials containing 200 mg of tedizolid as a lyophilized powder. Reconstitute the 200-mg vial with 4 mL of SWFI. Gently swirl the contents and let the vial stand until completely dissolved and any foam disperses. Solution should be clear and colorless to pale yellow. Tilt the upright vial and insert a needle attached to a syringe to the bottom corner of the vial. Withdraw 4 mL of the reconstituted solution. *Do not invert the vial during extraction* of its contents. Further dilute by slowly injecting the 4 mL into a 250-mL bag of NS. Invert the bag gently to mix. *Do NOT shake*; may cause foaming.

Filters:

Specific information not available.

Storage:

Before use, vials may be stored at CRT. Total time from reconstitution to dilution to completion of administration of both reconstituted vials and/or fully diluted solutions should not exceed 24 hours at RT or under refrigeration at 2° to 8° C (36° to 46° F).

COMPATIBILITY

Tedizolid is **compatible** only with NS. Manufacturer states, “Other IV substances, additives, or other medications should not be added to tedizolid single-use vials or infused simultaneously through the same IV line or through a common IV port. If the same IV line is used for sequential infusion of additional medications, the line should be flushed before and after infusion of tedizolid with NS.” It is **incompatible** with any solution containing divalent cations (e.g., calcium, magnesium), including LR injection and Hartmann’s solution.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 1 hour. **Do not administer as an IV push or bolus.** If a common IV line is used to administer other drugs in addition to tedizolid, flush the IV line before and after each tedizolid infusion with NS.

ACTIONS

Tedizolid phosphate belongs to the oxazolidinone class of antibacterial drugs. It is a phosphate prodrug and is converted to tedizolid by phosphatases. Its antibacterial activity is mediated by binding to the 50S subunit of the bacterial ribosome, resulting in inhibition of protein synthesis. This mechanism of action is different from that of other non–oxazodidinone class antibacterial drugs; therefore cross-resistance between tedizolid and other classes of antibacterial drugs is unlikely. Bacteriostatic against designated strains of *Staphylococcus*, *Streptococcus,* and *Enterococcus*; see Indications. Peak plasma concentrations are achieved at the end of the 1-hour infusion. Penetrates into the interstitial space fluid of adipose and skeletal muscle tissue with exposure similar to free-drug exposure in plasma. Approximately 70% to 90% bound to human plasma proteins. Half-life is approximately 12 hours. The majority of elimination occurs via the liver. Primarily excreted as a microbiologically inactive sulfate conjugate in feces with some excretion in urine.

INDICATIONS AND USES

Treatment of adult patients with acute bacterial skin and skin structure infections (ABSSSI) caused by susceptible isolates of designated gram-positive microorganisms, including *Staphylococcus aureus* (both methicillin-susceptible [MSSA] and methicillin-resistant [MRSA] strains).

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For IV use only. ■ Safety and efficacy for use in patients with neutropenia (neutrophil counts less than 1,000 cells/mm^3) have not been adequately evaluated. In an animal model of infection, the antibacterial activity of tedizolid was reduced in the absence of granulocytes. Consider alternative therapy when treating patients with neutropenia and ABSSSI. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to tedizolid. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, tedizolid should be used to treat only those infections proven or strongly suspected to be caused by bacteria. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported for nearly all systemic antibacterial agents and may range in severity from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with tedizolid.

Monitor:

Obtain baseline CBC with differential and platelets. ■ Monitor for S/S of hypersensitivity (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing).

Patient Education:

Review FDA-approved patient information. ■ Advise pregnant women and women of reproductive potential about possible risk to the fetus. ■ Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath, wheezing). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Based on animal studies, tedizolid may cause fetal harm when administered to pregnant women. Use during pregnancy only if the potential benefit outweighs the possible risk to the fetus. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Numbers in clinical studies insufficient to determine whether the elderly respond differently than do younger subjects. No overall differences in pharmacokinetics were observed between elderly subjects and younger subjects.

DRUG/LAB INTERACTIONS

Tedizolid did not detectably inhibit or induce the metabolism of **cytochrome P_{450} enzyme substrates.** There was no degradation of tedizolid in human liver microsomes, indicating that tedizolid is unlikely to be a substrate for hepatic CYP_{450} enzymes. ■ A reversible inhibitor of monoamine oxidase. Not evaluated because subjects taking MAO inhibitors were excluded from trials.

SIDE EFFECTS

The most common adverse reactions are diarrhea, dizziness, headache, infusion- or injection-related adverse reactions, nausea, and vomiting. CDAD, decreased WBC, dermatitis, eye disorders (e.g., asthenopia, blurred vision, visual impairment, vitreous floaters), flushing, hypersensitivity reactions, hypertension, hypoesthesia, increased hepatic transaminases, insomnia, myelosuppression (anemia, neutropenia, thrombocytopenia), oral candidiasis, palpitations, paresthesia, pruritus, seventh nerve paralysis, tachycardia, urticaria, and vulvovaginal mycotic infection have been reported. Peripheral and optic neuropathy have been described in patients treated with another member of the oxazolidinone class (e.g., linezolid) for longer than 28 days.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated (e.g., diphenhydramine, epinephrine, albuterol) and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of tedizolid. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. In the event of an overdose, discontinue tedizolid and provide supportive treatment as needed. Is not effectively removed from the circulation by hemodialysis.

TELAVANCIN BBW

(tel-a-**VAN**-sin)
Vibativ
Antibacterial (lipoglycopeptide)
pH 4 to 5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Complicated skin and skin structure infections (cSSSI):

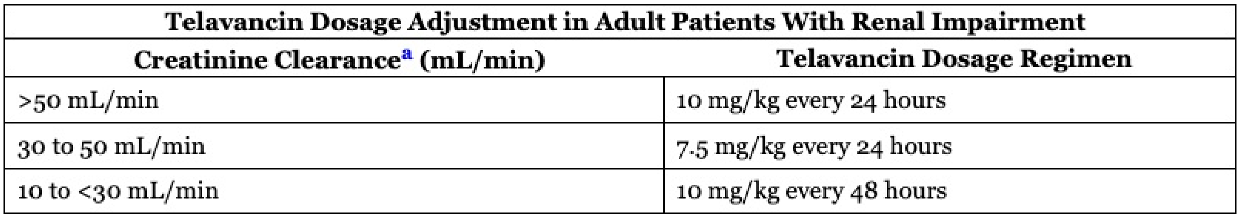
10 mg/kg as an infusion once every 24 hours for 7 to 14 days. Duration of therapy is dependent on severity and site of infection and on the patient’s clinical progress.

Hospital-acquired and ventilator-associated bacterial pneumonia (HABP/VABP):

10 mg/kg as an infusion once every 24 hours for 7 to 21 days. Duration of therapy is dependent on severity and site of infection and on the patient’s clinical progress.

DOSE ADJUSTMENTS

Dose adjustment required in renal impairment as outlined in the following chart.



Telavancin Dosage Adjustment in Adult Patients With Renal Impairment

Creatinine Clearance[a] (mL/min)	Telavancin Dosage Regimen
>50 mL/min	10 mg/kg every 24 hours
30 to 50 mL/min	7.5 mg/kg every 24 hours
10 to <30 mL/min	10 mg/kg every 48 hours

[a]Calculate using Cockcroft-Gault formula and ideal body weight. Use actual body weight if it is less than ideal body weight.

There is insufficient information to make specific dose recommendations for patients with end-stage renal disease (CrCl less than 10 mL/min), including patients undergoing hemodialysis. ■ Reduced doses may be indicated in the elderly based on age-related renal impairment. ■ No dose adjustment is recommended based on gender or in patients with mild or moderate hepatic impairment. Has not been studied in patients with severe hepatic impairment.

DILUTION

Reconstitute each 250-mg vial with 15 mL of D5W, SWFI, or NS (45 mL for a 750-mg vial). Resultant solution has a final concentration of 15 mg/mL. To minimize foaming during reconstitution, allow the vacuum of the vial to pull the diluent from the syringe into the vial. Do not forcefully inject the diluent into the vial. Do not forcefully shake the vial. Reconstitution time is generally under 2 minutes but can occasionally take as long as 20 minutes. Mix thoroughly to dissolve contents completely. Discard vial if vacuum does not pull diluent into vial. Doses of 150 to 800 mg must be further diluted in 100 to 250 mL of D5W, NS, or LR. Doses less than 150 mg or greater than 800 mg must be diluted in a sufficient volume to provide a final concentration of 0.6 to 8 mg/mL. Do not shake the final infusion solution.

Storage:

Store unopened vials in refrigerator at 2° to 8° C (36° to 46° F). Excursions up to 25° C (77° F) are acceptable. Reconstituted and diluted solutions are stable for 12 hours at RT and for 7 days refrigerated. Total time in the vial plus the time in the infusion bag should not exceed 12 hours at RT and 7 days under refrigeration. The diluted solution can also be stored at −30° to −10° C (−22° to −14° F) for up to 32 days.

COMPATIBILITY

Manufacturer states, “Additives or other medications should not be added to telavancin single-use vials or infused simultaneously through the same IV line. If the same IV line is used for sequential infusion of additional medications, the line should be flushed before and after infusions of telavancin with D5W, NS, or LR.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose equally distributed as an infusion over 60 minutes. Rapid IV infusions can cause “red man syndrome”–like infusion-related reactions, including flushing of the upper body, urticaria, pruritus, or rash. Stopping or slowing the infusion may result in cessation of these reactions. If the same IV line is used for sequential infusion of additional medications, the line should be flushed before and after infusions of telavancin with D5W, NS, or LR.

ACTIONS

A lipoglycopeptide antibacterial that is a synthetic derivative of vancomycin. Bactericidal against gram-positive organisms, including susceptible strains of staphylococci, streptococci, and vancomycin-susceptible enterococci. Exerts bactericidal action through inhibition of cell wall synthesis. Highly protein bound, primarily to albumin. The metabolic pathway for telavancin has not been identified. Half-life is 6.6 to 9.6 hours. Primarily excreted by the kidney.

INDICATIONS AND USES

Treatment of adult patients with complicated skin and skin structure infections (cSSSI) caused by susceptible isolates of gram-positive microorganisms, including *Staphylococcus aureus* (including methicillin-susceptible and methicillin-resistant isolates), *Streptococcus pyogenes, Streptococcus agalactiae, Streptococcus anginosus* group, or *Enterococcus faecalis* (vancomycin-susceptible isolates only). ■ Treatment of adult patients with hospital-acquired and ventilator-associated bacterial pneumonia (HABP/VABP) caused by susceptible isolates of *Staphylococcus aureus* (including methicillin-susceptible and methicillin-resistant isolates). Reserve use for when alternative treatments are not suitable.

CONTRAINDICATIONS

Known hypersensitivity to telavancin. ■ Use of IV unfractionated heparin sodium is contraindicated; see Drug/Lab Interactions.

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, telavancin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies are necessary to determine susceptibility of the causative organism to telavancin. ■ Combination therapy may be clinically indicated if the documented or presumed pathogens include gram-negative organisms. ■ Prolonged use of drug may result in superinfection caused by overgrowth of nonsusceptible organisms. ■ New-onset or worsening renal impairment has been reported. Patients with underlying renal dysfunction or risk factors for renal dysfunction (diabetes mellitus, CHF, or hypertension) may be at increased risk. Patients who received concomitant medications known to affect kidney function (e.g., NSAIDs, ACE inhibitors, and loop diuretics) may also be at higher risk; see Drug Interactions. ■ Patients with pre-existing moderate to severe renal impairment (CrCl less than or equal to 50 mL/min) who were treated with telavancin for HABP/VABP had increased mortality observed versus vancomycin. Use of telavancin in patients with pre-existing moderate to severe renal impairment should be considered only when the anticipated benefit outweighs the potential risk. ■ Data from cSSSI trials suggest that clinical cure rates were lower in patients with baseline CrCl less than or equal to 50 mL/min. The same decrease in clinical cure rates was not seen in vancomycin-treated patients. These data should be considered when selecting antibacterial therapy for use in patients with baseline moderate/severe renal impairment. ■ Serious and sometimes fatal hypersensitivity reactions, including anaphylactic reactions, may occur after the first dose or subsequent doses. Telavancin is a semi-synthetic derivative of vancomycin; it is unknown whether patients with hypersensitivity reactions to vancomycin will experience cross-reactivity to telavancin. Use with caution in patients with known hypersensitivity to vancomycin. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with telavancin. ■ Infusion-related reactions have been reported; see Rate of Administration and Monitor. ■ Has caused prolongation of the QTc interval. Use with caution in patients who are taking drugs known to prolong the QTc interval. Avoid use in patients with congenital long QT syndrome, known prolongation of the QTc interval, uncompensated heart failure, or severe left ventricular hypertrophy. ■ Does not interfere with coagulation. Increased risk of bleeding and effects on platelet aggregation have not been observed. However, has been shown to affect certain anticoagulation tests; see Drug/Lab Interactions. ■ There is no known cross-resistance between telavancin and other classes of antibiotics. Some vancomycin-resistant enterococci have a reduced susceptibility to telavancin. ■ See Maternal/Child.

Monitor:

Obtain baseline CBC with differential and SCr. Monitor SCr every 48 to 72 hours, or more frequently if indicated, and at the end of therapy. If renal function deteriorates, the risk versus benefit of continuing therapy should be assessed. ■ Monitor for possible infusion-related reactions. ■ Monitor for S/S of hypersensitivity reactions.

Patient Education:

Review manufacturer-supplied medication guide. ■ Women of childbearing potential should have a pregnancy test before initiating therapy. Effective birth control should be used throughout therapy. A pregnancy registry has been established to monitor the outcomes of women who become pregnant while receiving telavancin. ■ Report all side effects promptly. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after telavancin has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category C: adverse developmental outcomes in three animal species at clinically relevant doses raise concerns about potential adverse developmental outcomes in humans. Avoid use during pregnancy unless potential benefit justifies potential risk. ■ Women with childbearing potential should have a serum pregnancy test before receiving telavancin. A pregnancy registry has been established to monitor pregnancy outcomes in women exposed to telavancin during pregnancy. ■ Safety for use in breast-feeding not established and effects unknown; use caution. ■ Safety and effectiveness for use in pediatric patients have not been studied.

Elderly:

In cSSSI trials, lower clinical cure rates were seen in patients over 65 years of age. Overall, treatment-emergent adverse events occurred with similar frequencies in patients of all age-groups studied. However, adverse events indicative of renal impairment occurred more frequently in the elderly. In HABP/VABP trials, treatment-emergent adverse events, deaths, and other serious adverse events occurred more often in patients 65 years of age or older. Consider age-related renal impairment; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Use with caution in patients taking **medications known to prolong the QTc interval** (e.g., amiodarone and other antiarrhythmics, diphenhydramine, fosphenytoin, furosemide, itraconazole). Effects may be additive. ■ Concomitant use with **other agents that can affect renal function** (e.g., NSAIDs, diuretics, and ACE inhibitors) may increase the risk of renal toxicity. ■ May affect **certain anticoagulation tests.** Increases in PT, INR, aPTT, ACT, and coagulation-based factor X activity assays have been observed. Effects dissipate over time. Interference seen when using samples drawn between 0 and 18 hours after telavancin administration. Collect blood samples for these coagulation tests immediately before a patient’s next telavancin dose to minimize interaction. Because aPPT test results are expected to be artificially prolonged after telavancin administration, concurrent use of intravenous unfractionated **heparin** is contraindicated. For patients who require aPTT monitoring while being treated with telavancin, a non–phospholipid-dependent coagulation test such as a factor Xa (chromogenic) assay or an alternative anticoagulant not requiring aPTT monitoring should be considered. ■ Interferes with **urine qualitative dipstick protein assays** and **quantitative dye methods** (e.g., pyrogallol red-molybdate). However, microalbumin assays are not affected and can be used to monitor urinary protein excretion.

SIDE EFFECTS

The most common side effects include diarrhea, foamy urine, nausea, taste disturbances, and vomiting. The most serious side effects include cardiac events, CDAD, infusion-related reactions, nephrotoxicity (increased SCr, renal insufficiency, renal failure), and respiratory events. The most common events leading to discontinuation of therapy were acute renal failure, nausea, QTc prolongation, and rash. Other reported side effects include abdominal pain, decreased appetite, dizziness, infusion site pain and erythema, pruritus, and rigors.

Post-Marketing:

Hypersensitivity reactions, including anaphylaxis.

ANTIDOTE

Notify the physician of all side effects. Initiate supportive care as indicated. Infusion-related reactions may respond to temporarily discontinuing or slowing the rate of infusion. Consider alternative antimicrobial therapy in patients who develop renal toxicity. Discontinue telavancin at the first sign of skin rash or other sign of hypersensitivity. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. There is no information on the use of hemodialysis or continuous venovenous hemofiltration in toxicity.

TEMOZOLOMIDE

(te-moe-**ZOE**-loe-mide)
Temodar
Antineoplastic (alkylating agent)

USUAL DOSE

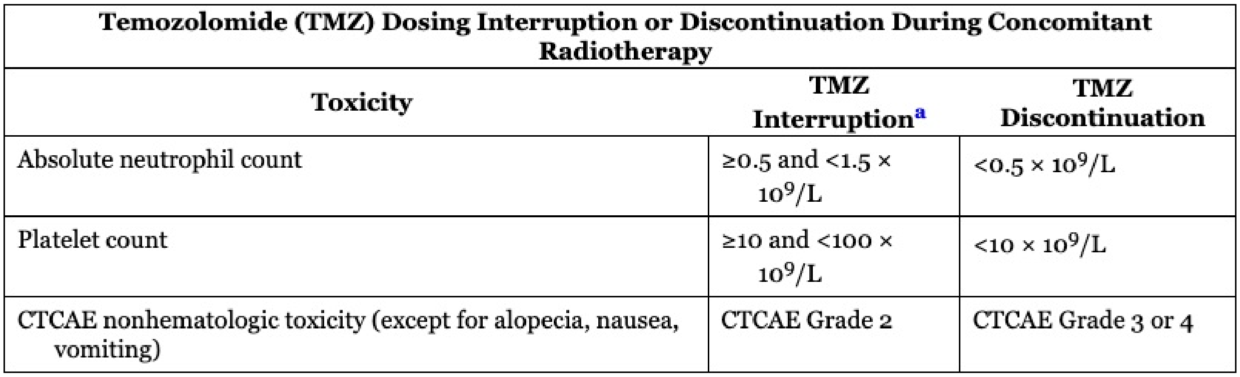
Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

IV and oral doses are therapeutically equivalent if the IV dose is administered equally distributed over 90 minutes. The oral form should be used as soon as tolerated by the patient.

Newly diagnosed glioblastoma multiforme (GBM [high-grade glioma]): Concomitant phase:75 mg/M^2 daily for 42 days. Given concomitantly with focal radiotherapy. No dose reductions are recommended during the concomitant phase; however, dose interruptions or discontinuation may occur based on toxicity. The temozolomide dose should be continued throughout the 42-day concomitant period up to 49 days if all of the following conditions are met:

- Absolute neutrophil count must be equal to or greater than 1.5 × 10^9/L (1,500/mm^3).
- Platelet count must be equal to or greater than 100 × 10^9/L (100,000/mm^3).
- Nonhematologic toxicity must be equal to or less than Grade 1 (except for alopecia, nausea, and vomiting).
- CBC and platelet count should be obtained weekly.
- Interrupt or discontinue temozolomide dosing based on the hematologic and nonhematologic criteria in the following chart.



Temozolomide (TMZ) Dosing Interruption or Discontinuation During Concomitant Radiotherapy

Toxicity	TMZ Interruption[a]	TMZ Discontinuation
Absolute neutrophil count	≥0.5 and <1.5 × 10^9/L	<0.5 × 10^9/L
Platelet count	≥10 and <100 × 10^9/L	<10 × 10^9/L
CTCAE nonhematologic toxicity (except for alopecia, nausea, vomiting)	CTCAE Grade 2	CTCAE Grade 3 or 4

TMZ, Temozolomide; *CTCAE,* Common Terminology Criteria for Adverse Events.

[a] Treatment with concomitant TMZ could be continued when all of the following conditions are met: ANC ≥1.5 × 109/L, platelet count ≥100 × 109/L, CTC nonhematologic toxicity Grade ≤1 (except for alopecia, nausea, vomiting).

Prophylaxis against *Pneumocystis jiroveci* pneumonia (PCP):

Required for all patients during this concomitant therapy. PCP prophylaxis should be continued in patients who develop lymphocytopenia until they recover from lymphocytopenia (CTC Grade ≤1).

Newly diagnosed glioblastoma multiforme (GBM [high-grade glioma]):

Maintenance phase:

4 weeks after completing the temozolomide plus focal radiotherapy phase, temozolomide is administered for an additional 6 cycles of maintenance.

Cycle 1:

The initial dose is 150 mg/M^2 once daily for 5 days followed by 23 days without treatment (a 28-day cycle); see Dose Adjustments.

Cycles 2 through 6:

The dose can be increased to 200 mg/M^2 if the following conditions are met:

- Absolute neutrophil count is equal to or greater than 1.5 × 10^9/L (1,500/mm^3)
- Platelet count is equal to or greater than 100 × 10^9/L (100,000/mm^3)
- Nonhematologic toxicity is equal to or less than Grade 2 (except for alopecia, nausea, and vomiting).

The dose remains at 200 mg/M^2 per day for the first 5 days of each subsequent cycle except if toxicity occurs. If the dose was not increased at Cycle 2, it should not be increased for subsequent cycles. See Dose Adjustments for dose reduction or discontinuation during maintenance.

Refractory anaplastic astrocytoma:

150 mg/M^2 once daily for 5 consecutive days for each 28-day treatment cycle. This dose may be increased to 200 mg/M^2/day if both the nadir and day of dosing (Day 29, Day 1 of next cycle) ANC are equal to or greater than 1.5 × 10^9/L (1,500/mm^3) and the nadir and day of dosing (Day 29, Day 1 of next cycle) platelet count are equal to or greater than 100 × 10^9/L (100,000/mm^3). During treatment, a CBC should be obtained on Day 22 (21 days after the Day 1 dose of temozolomide) or within 48 hours of that day for each cycle. Repeat weekly until the ANC is above 1.5 × 10^9/L (1,500/mm^3) and the platelet count exceeds 100 × 10^9/L (100,000/mm^3). The next cycle of temozolomide should not be started until the ANC and platelet count exceed these levels. If the ANC falls to <1 × 10^9/L (1,000/mm^3) or the platelet count is <50 × 10^9/L (50,000/mm^3) during any cycle, reduce the next cycle by 50 mg/M^2 but not below 100 mg/M^2 (the lowest recommended dose). Therapy can be continued until disease progression. See the flowchart in Dose Adjustments.

DOSE ADJUSTMENTS

Newly diagnosed glioblastoma multiforme (GBM):

Temozolomide dose must be adjusted according to the nadir ANC and platelet counts in the previous cycle and the ANC and platelet counts at the time of initiating the next cycle. Obtain a CBC and platelet count weekly during the concomitant phase and as indicated during the 4-week interim before beginning the maintenance phase. Obtain a baseline CBC and platelet count before beginning a cycle and repeat on Day 22 (21 days after the first dose of temozolomide in the cycle or within 48 hours of that day). Repeat weekly until the ANC is above 1.5 × 10^9/L (1,500/mm^3) and the platelet count exceeds 100 × 10^9/L (100,000/mm^3). The next cycle of temozolomide should not be started until the ANC and platelet count exceed these levels. This sequence is repeated for Cycles 1 through 6 of maintenance dosing. Base dose reductions during the next cycle on the lowest blood counts and worst nonhematologic toxicity during the previous cycle. Dose reductions or discontinuations during maintenance should be applied according to the following two charts.

Temozolomide Dose Levels for Maintenance Treatment		
Dose Level	**Dose (mg/M^2/day)**	**Remarks**
−1	100 mg/M^2/day	Reduction for prior toxicity
0	150 mg/M^2/day	Dose during Cycle 1
1	200 mg/M^2/day	Dose during Cycles 2 through 6 in absence of toxicity

Temozolomide Dose Reduction or Discontinuation During Maintenance Treatment		
Toxicity	**Reduce TMZ by 1 Dose Level**[a]	**Discontinue TMZ**
ANC	$<1 \times 10^9$/L	See [b] in footnote
Platelet count	$<50 \times 10^9$/L	See [b] in footnote
CTC nonhematologic toxicity (except for alopecia, nausea, vomiting)	CTC Grade 3	CTC Grade 4

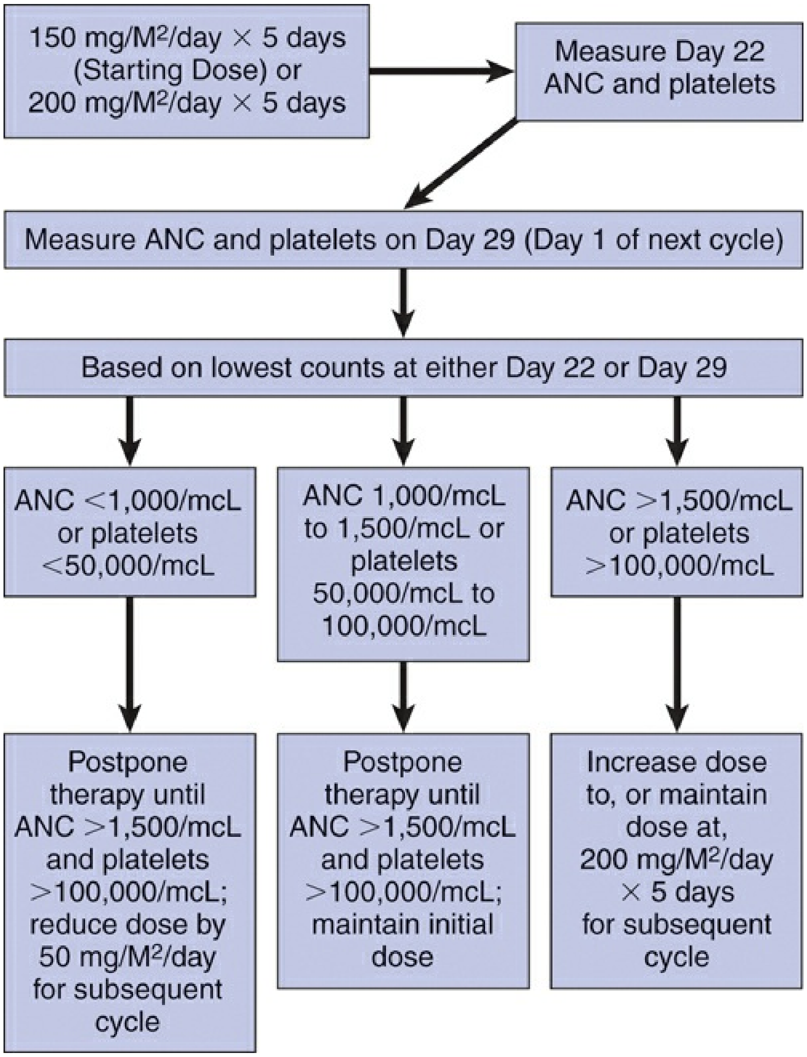
TMZ, Temozolomide; *CTC,* Common Terminology Criteria.

[a] See preceding chart for temozolomide dose levels for maintenance treatment.

[b] TMZ is to be discontinued if a dose reduction to <100 mg/M^2 is required or if the same Grade 3 nonhematologic toxicity (except for alopecia, nausea, vomiting) recurs after dose reduction.

See the next page for temozolomide dose modifications for refractory anaplastic astrocytoma.

Temozolomide Dose Modification Table for Refractory Anaplastic Astrocytoma:



150 mg/M2/day × 5 days (Starting Dose) or 200 mg/M2/day × 5 days
Measure Day 22 ANC and platelets
Measure ANC and platelets on Day 29 (Day 1 of next cycle)
Based on lowest counts at either Day 22 or Day 29
ANC <1,000/mcL or platelets <50,000/mcL
ANC 1,000/mcL to 1,500/mcL or platelets 50,000/mcL to 100,000/mcL
ANC >1,500/mcL or platelets >100,000/mcL
Postpone therapy until ANC >1,500/mcL and platelets >100,000/mcL; reduce dose by 50 mg/M2/day for subsequent cycle
Postpone therapy until ANC >1,500/mcL and platelets >100,000/mcL; maintain initial dose
Increase dose to, or maintain dose at, 200 mg/M2/day × 5 days for subsequent cycle

DILUTION

Specific techniques required; see Precautions.

Bring vial(s) to room temperature before reconstitution. Reconstitute each 100-mg vial with 41 mL of SWFI. Swirl gently to dissolve; ***do not shake;*** will yield a concentration of 2.5 mg/mL of temozolomide. ***Do not further dilute*** the reconstituted solution. Withdraw up to 40 mL from each vial and transfer into an empty 250-mL PVC infusion bag for delivery with an infusion pump.

Filters:

Specific information not available.

Storage:

Refrigerate single-use vials at 2° to 8° C (36° to 46° F). Store reconstituted product at RT. Reconstituted solution must be used within 14 hours, including infusion time.

COMPATIBILITY

Manufacturer states, “Other medications should not be infused simultaneously through the same IV line.” May be administered only in the same infusion line as NS.

RATE OF ADMINISTRATION

A single dose equally distributed over 90 minutes. Use of an infusion pump is recommended. Bioequivalence was established only with the 90-minute infusion. Infusion over a longer or shorter period may result in suboptimal dosing. In addition, the possibility of an increase in infusion-related adverse reactions cannot be ruled out. Flush IV lines before and after temozolomide infusion. Infusion must be complete within 14 hours of reconstitution.

ACTIONS

An imidazotetrazine derivative and alkylating agent. It is not directly active but undergoes rapid nonenzymatic conversion, as dacarbazine does, to the reactive compound 5-(3-methyl triazen-1-yl)-imidazole-4-carboxamide (MTIC) and to temozolomide acid metabolite. Cytotoxicity is thought to be due primarily to alkylation of DNA. Weakly bound to plasma proteins. Rapidly eliminated with a mean elimination half-life of 1.8 hours. Some excretion in urine and a very small amount in feces.

INDICATIONS AND USES

Treatment of adults with newly diagnosed glioblastoma multiforme. Initially given concomitantly with radiotherapy and then continued as maintenance treatment. ■ Treatment of adults with refractory anaplastic astrocytoma (i.e., adults who have experienced disease progression on a drug regimen containing nitrosourea and procarbazine).

CONTRAINDICATIONS

Known history of hypersensitivity reaction to temozolomide or any of its components (e.g., urticaria, allergic reaction including anaphylaxis, toxic epidermal necrolysis, and Stevens-Johnson syndrome). ■ Known history of hypersensitivity to dacarbazine.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Usually administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Myelosuppression may be severe and dose limiting. May include prolonged pancytopenia, which may result in aplastic anemia. Deaths have been reported. Risk may be increased with concomitant use of other medications associated with aplastic anemia (e.g., carbamazepine, phenytoin, sulfamethoxazole/trimethoprim). ■ Risk of myelosuppression increased in women and the elderly. ■ Cases of myelodysplastic syndrome and secondary malignancies, including myeloid leukemia, have been observed. ■ Prophylaxis against *Pneumocystis* pneumonia (PCP) is required for all patients being treated for newly diagnosed glioblastoma multiforme receiving concomitant temozolomide and radiotherapy for the 42-day regimen. The longer dosing regimen may increase the risk of PCP; however, all patients, particularly those receiving steroids, should be monitored closely for symptoms of PCP regardless of the regimen. ■ Severe, sometimes fatal hepatotoxicity have been reported. ■ Use caution in patients with severe renal or hepatic impairment.

Monitor:

Obtain a baseline CBC and platelet count. See Usual Dose for minimum levels required before administration of temozolomide. ■ Obtain baseline liver function tests. Repeat midway through the first cycle, before each subsequent cycle, and approximately 2 to 4 weeks after the last dose of temozolomide.

Patients with newly diagnosed GBM:

Obtain a CBC and platelet count weekly during the concomitant phase and as indicated during the 4-week interim before beginning the maintenance phase. Obtain a baseline CBC and platelet count before beginning a maintenance dose (28-day cycles) and repeat on Day 22 (21 days after the first maintenance dose of temozolomide or within 48 hours of that day). Repeat weekly until the ANC is above 1.5×10^9/L (1,500/mm^3) and the platelet count exceeds 100×10^9/L (100,000/mm^3). This sequence is repeated for Cycles 1 through 6 of maintenance dosing.

Patients with refractory anaplastic astrocytoma:

Obtain a CBC and platelet count on Day 1 of each cycle. During treatment (28-day cycles), a CBC should be obtained on Day 22 (21 days after the Day 1 dose of temozolomide or within 48 hours of that day for each cycle). Repeat weekly until the ANC is above 1.5×10^9/L (1,500/mm^3) and the platelet count exceeds 100×10^9/L (100,000/mm^3). Myelosuppression usually occurred within the first few cycles of therapy and was not cumulative. It occurred late in the treatment cycle and returned to normal, on average, within 14 days of nadir counts. (The median nadirs occurred at 26 days for platelets and 28 days for neutrophils.)

All indications:

Nausea and vomiting may be significant. Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Regardless of the regimen, monitor all patients, particularly those receiving steroids, for symptoms of PCP (dyspnea; fever; dry, nonproductive cough; characteristic x-ray).

Patient Education:

Read the FDA-approved patient information. ■ Avoid pregnancy; use of effective contraception recommended for females of reproductive potential during treatment with temozolomide and for at least 6 months after the final dose. Because of the potential for embryo-fetal toxicity and genotoxic effects on sperm cells, advise male patients with pregnant partners or female partners of reproductive potential to use condoms during treatment with temozolomide and for at least 3 months after the final dose. ■ May impair male fertility. ■ Male patients should not donate semen during treatment and for at least 3 months after the final dose. ■ Promptly report a rash; swelling of the face, throat, or tongue; severe skin reaction; or troubled breathing. ■ Report IV site burning or stinging promptly. ■ Secondary malignancies have been reported. ■ See Maternal/Child. ■ See Appendix D, p. 1311. ■ Additional precautions are required with the capsule form.

Maternal/Child:

Based on its mechanism of action and findings from animal studies, temozolomide can cause fetal harm. Spontaneous abortions and congenital malformations, including polymalformations with central nervous system, facial, cardiac, skeletal, and genitourinary system anomalies, have been reported. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. A 5-day regimen every 28 days using the oral formulation has been studied in selected pediatric patients from 3 to 18 years of age. Toxicity profile was similar to that seen in adults.

Elderly:

Numbers in clinical studies are insufficient to determine whether the elderly respond differently than younger subjects. Dose selection should be cautious based on the potential for decreased organ function and concomitant disease or drug therapy. ***In newly diagnosed patients with glioblastoma multiforme,*** side effects were similar to those seen in younger patients. In the ***anaplastic astrocytoma study,*** patients 70 years or older had a higher incidence of Grade 4 neutropenia and Grade 4 thrombocytopenia in the first cycle of therapy.

DRUG/LAB INTERACTIONS

Valproic acid decreases the oral clearance of temozolomide by about 5%; clinical significance is not known. ■ Administration of **live attenuated viral or bacterial vaccines** should be avoided.

SIDE EFFECTS

Newly diagnosed glioblastoma multiforme:

Myelosuppression may be severe and dose limiting. May include prolonged pancytopenia, which may result in aplastic anemia; deaths have been reported. Alopecia, anorexia, constipation, headache, nausea and vomiting, and thrombocytopenia were the most frequently reported side effects. The most commonly reported severe or life-threatening reactions were convulsions, fatigue, headache, and thrombocytopenia. Abdominal pain, arthralgia, blurred vision, confusion, coughing, diarrhea, dizziness, dry skin, dyspnea, erythema, hypersensitivity reactions (including anaphylaxis), insomnia, memory impairment, pruritus, radiation injury, rash, stomatitis, taste perversion, and weakness have also been reported.

Refractory anaplastic astrocytoma:

Fatigue, headache, and nausea and vomiting were the most frequently reported side effects. Myelosuppression (neutropenia and thrombocytopenia) was the dose-limiting adverse reaction. Abdominal pain, abnormal coordination, abnormal gait, abnormal vision (blurred vision, vision changes, visual deficit), adrenal hypercorticism, amnesia, anemia, anorexia, anxiety, asthenia, ataxia, back pain, breast pain (female), confusion, constipation, convulsions (local and general), coughing, depression, diarrhea, diplopia, dizziness, dysphasia, fever, hemiparesis, insomnia, lymphopenia, myalgia, paresis, paresthesia, peripheral edema, pharyngitis, pruritus, rash, sinusitis, somnolence, URI, urinary incontinence, UTI, viral infection, and weight increase have been reported.

Injection site reactions:

Erythema, irritation, pain, pruritus, swelling, and warmth at the infusion site; hematoma; and petechiae.

Post-Marketing:

Alveolitis, cholestasis, diabetes insipidus, elevation of liver enzymes, erythema multiforme, hepatitis, hepatotoxicity (severe and sometimes fatal), hyperbilirubinemia, hypersensitivity reactions (including anaphylaxis), serious opportunistic infections with bacterial, viral (primary and reactivated), fungal, and protozoan organisms, interstitial pneumonitis, pneumonitis, prolonged pancytopenia that may result in aplastic anemia with fatal outcomes, pulmonary fibrosis, Stevens-Johnson syndrome, and toxic epidermal necrolysis.

ANTIDOTE

Keep physician informed of all side effects and CBC results. Temozolomide may need to be reduced or discontinued. Symptomatic and supportive treatment is indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Precautions are indicated for cancer patients with erythropoietin-stimulating agents (ESAs); see darbepoetin alfa and epoetin alfa monographs. Treat hypersensitivity reactions and/or anaphylaxis as indicated (e.g., epinephrine, corticosteroids, oxygen, and antihistamines [diphenhydramine]). There is no specific antidote. In the event of an overdose, hematologic evaluation is needed, and supportive measures should be provided as necessary. Resuscitate as indicated.

TEMSIROLIMUS

(**TEM**-sir-**OH**-li-mus)
Torisel
Antineoplastic (kinase inhibitor)

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Premedication:

To minimize the incidence of hypersensitivity reactions, administer diphenhydramine 25 to 50 mg IV 30 minutes before the start of each dose of temsirolimus; see Precautions and Monitor.

Temsirolimus:

25 mg as an infusion once a week until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

Hold for absolute neutrophil count (ANC) less than 1,000/mm^3, platelet count less than 75,000/mm^3, or CTCAE Grade 3 or greater adverse reactions. Once toxicities have resolved to Grade 2 or less, restart therapy with the dose reduced by 5 mg/week to a dose no lower than 15 mg/week. ■ Consider dose reduction to 12.5 mg/week when coadministered with a strong CYP3A4 inhibitor; see Drug/Lab Interactions. If the strong inhibitor is discontinued, wait approximately 1 week before adjusting the temsirolimus dose upward to the indicated dose. ■ Consider a dose increase to 50 mg/week when coadministered with a strong CYP3A4 inducer; see Drug/Lab Interactions. If the strong inducer is discontinued, the temsirolimus dose should be returned to the dose used prior to initiation of the strong CYP3A4 inducer. ■ Decrease dose to 15 mg/week in patients with mild hepatic impairment (bilirubin greater than 1 to 1.5 times the ULN or AST greater than ULN but bilirubin equal to or less than ULN); see Contraindications. ■ No dose adjustment indicated based on age, race, gender, or renal status. Not studied in hemodialysis patients.

DILUTION

Specific techniques required; see Precautions and Compatibility.

Available as a kit containing a vial of temsirolimus and a vial of a manufacturer-supplied diluent. Temsirolimus and diluent vials contain overfill. A two-step dilution process is required. Reconstitute the temsirolimus vial with 1.8 mL of the provided diluent. Invert the vial several times to mix thoroughly. Allow time for foam to subside. Final concentration in temsirolimus vial is 10 mg/mL. Solution will be clear to slightly turbid and colorless to light-yellow. Withdraw the required amount of reconstituted temsirolimus and inject into a 250-mL container ***(glass, polyolefin, or polypropylene)*** of NS. Invert bag to mix; **see Compatibility.** Avoid excessive shaking. Use of non-DEHP, non-polyvinylchloride (PVC) tubing (polyethylene-lined administration set is recommended) with appropriate filter is recommended. If a PVC administration set must be used, it should not contain DEHP. Temsirolimus contains polysorbate 80 when diluted, which increases the rate of DEHP extraction from PVC.

Filter:

Use of an in-line polyethersulfone filter with a pore size not greater than 5 microns is recommended. If an administration set with an in-line filter is not available, a polyethersulfone end-filter should be used. The use of both an in-line and end-filter is not recommended.

Storage:

Store unopened vials at 2° to 8° C (36° to 46° F). Protect from light. During handling and preparation, protect from excessive room light or sunlight. The temsirolimus/diluent mixture (10 mg/mL) is stable for up to 24 hours below 25° C (77° F) in the temsirolimus vial. Administration of the final product diluted in NS should be completed within 6 hours of adding the temsirolimus/diluent mixture to the NS.

COMPATIBILITY

Manufacturer states, "Final dilution for infusion should be stored in bottles (glass, polypropylene) or plastic bags (polypropylene, polyolefin) and administered through polyethylene-lined administration sets." Non–DEHP-containing materials must be used for administration. Manufacturer also states that undiluted temsirolimus should not be added directly to aqueous infusion solutions. A precipitate will form. In addition, "The stability of temsirolimus in other infusion solutions has not been evaluated. Addition of other drugs or nutritional agents to admixtures of temsirolimus in NS has not been evaluated and should be avoided. Temsirolimus is degraded by both acids and bases, and thus combinations of temsirolimus with agents capable of modifying solution pH should be avoided."

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 to 60 minutes. Use of an infusion pump is recommended. Increase duration of infusion to 60 minutes in patients who experience a hypersensitivity reaction.

ACTIONS

An inhibitor of mTOR (mammalian target of rapamycin). Binds to an intracellular protein (FKBP-12); this protein-drug complex inhibits the activity of mTOR that controls cell division. Results in a cell cycle–specific (G1) growth arrest in treated tumor cells. In in vitro studies, temsirolimus inhibited the activity of mTOR and resulted in reduced levels of hypoxia-inducible factors HIF-1α and HIF-2α and the vascular endothelial growth factor. Both temsirolimus and sirolimus are extensively partitioned into formed blood elements. Extensively metabolized, primarily by cytochrome P_{450} 3A4. Sirolimus is the principal metabolite and is active. Elimination is primarily via the feces and to a small extent via urine. Mean half-lives of temsirolimus and sirolimus were 17.3 and 54.6 hours, respectively.

INDICATIONS AND USES

Treatment of advanced renal cell carcinoma.

CONTRAINDICATIONS

Bilirubin greater than 1.5 times the ULN; see Dose Adjustments and Precautions.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Should be administered by or under the direction of the physician specialist in facilities equipped to monitor the patient and respond to any medical emergency. ■ Hypersensitivity/infusion reactions have been reported. May occur early in the first infusion but may also occur with subsequent infusions. Premedication required to minimize the chance of a reaction; see Usual Dose. Use with caution in patients with known hypersensitivity to temsirolimus, its metabolites (including sirolimus), polysorbate 80, or any other components of the product. Use caution in patients who have known hypersensitivity to an antihistamine or who cannot receive prophylactic treatment with an antihistamine for medical reasons; see Monitor. ■ Patients with moderate and severe hepatic impairment had increased rates of adverse reactions and deaths. Use caution when treating patients with mild hepatic impairment; see Dose Adjustments and Contraindications. ■ Hyperglycemia/glucose intolerance is common. Initiation of or an increase in the dose of insulin and/or oral hypoglycemic agent therapy may be required. ■ Elevated cholesterol and triglycerides are common. Initiation or adjustment of existing therapy may be required. ■ May cause immunosuppression, thus increasing the risk of infections, including opportunistic infections. *Pneumocystis jiroveci* pneumonia (PJP), including fatalities, has been reported. May be associated with concomitant use of corticosteroids or other immunosuppressants. Consider prophylaxis of PJP when concomitant use of corticosteroids or other immunosuppressive agents is required. ■ Cases of interstitial lung disease, some resulting in death, have been reported. ■ Cases of fatal bowel perforation have been reported. ■ Rapidly progressive and sometimes fatal acute renal failure has occurred. ■ Has been associated with abnormal wound healing. Exercise caution when temsirolimus is used in the perioperative period. ■ Patients who have CNS tumors and/or are receiving anticoagulation therapy may be at increased risk of intracerebral bleeding. ■ Proteinuria (including cases of nephrotic syndrome) has occurred. ■ The use of live virus vaccines and close contact with those who have received live virus vaccines should be avoided. See Drug Interactions.

Monitor:

Obtain baseline and weekly CBC with differential and platelet count. Obtain a baseline chemistry panel, including bilirubin and liver function tests (ALT, AST), and repeat every 2 weeks. Monitor urine protein before the start of temsirolimus therapy and periodically thereafter. Obtain baseline radiographic assessment by lung CT or chest x-ray. Repeat assessments periodically. ■ Monitor for S/S of a hypersensitivity/infusion reaction (e.g., anaphylaxis, apnea, bronchospasm, chest pain, dyspnea, flushing, hypotension, loss of consciousness, rash). If a reaction occurs, the infusion should be stopped and the patient should be observed for at least 30 to 60 minutes (depending on the severity of the reaction). At the discretion of the physician, and after a benefit-risk assessment, treatment may be resumed with the administration of an H_1-receptor antagonist (such as diphenhydramine) if not previously administered and/or an H_2-receptor antagonist (e.g., famotidine 20 mg IV) approximately 30 minutes before restarting the temsirolimus infusion. The infusion may be resumed at a slower rate; see Rate of Administration. ■ Monitor for S/S of angioedema when temsirolimus is given concomitantly with ACE inhibitors or calcium channel blockers. ■ Monitor serum glucose, cholesterol, and triglycerides before and during therapy. ■ Monitor for S/S of infection. ■ Monitor respiratory status. Patients may present with symptoms such as dyspnea, cough, hypoxia, and fever or may be asymptomatic. If clinically significant respiratory symptoms develop, consider withholding temsirolimus until after recovery of symptoms and improvement of radiographic findings related to pneumonitis. Opportunistic infections such as PJP should be considered in the differential diagnosis. Empiric treatment with corticosteroids and/or antibiotics may be considered. ■ Monitor for S/S of bowel perforation (abdominal pain, acute abdomen, bloody stools, diarrhea, fever, metabolic acidosis). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3); see Dose Adjustments and Contraindications. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Review medical history with health care provider. Temsirolimus may affect existing medical conditions (e.g., diabetes, high cholesterol, hyperlipidemia). Therapy may need to be adjusted. ■ Review medication list (prescription, over-the-counter, and herbal [including past or present use of corticosteroids or immunosuppressants]) with health care provider. Interactions are possible. ■ Promptly report any S/S of a hypersensitivity reaction (chest tightness, dyspnea, facial swelling, flushing, pruritus, rash, urticaria). ■ Avoid pregnancy. Use effective contraception during treatment and for 3 months after completion of therapy. Men with partners of childbearing potential should use reliable contraception during treatment and for 3 months after completion of therapy. ■ Male and female fertility may be compromised. ■ Report excessive thirst or any increase in volume or frequency of urination. ■ Promptly report S/S of nephrotic syndrome (e.g., fatigue; loss of appetite; swelling around the eyes, ankles, and feet; and weight gain). Acute renal failure may occur. ■ Promptly report S/S of infection, new or worsening respiratory symptoms, new or worsening abdominal pain, or blood in stools. ■ Wound healing complications may occur while on therapy. ■ The use of live virus vaccines and close contact with those who have received live virus vaccines should be avoided. ■ Increased risk of intracerebral bleed in patients who have CNS tumors and/or are receiving anticoagulants.

Maternal/Child:

Avoid pregnancy; may cause fetal harm. ■ Do not breast-feed during treatment with temsirolimus and for 3 weeks after the final dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Elderly patients may be more likely to experience certain side effects, including diarrhea, edema, and pneumonia.

DRUG/LAB INTERACTIONS

Concomitant use of **strong CYP3A4 inhibitors** (e.g., atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, or voriconazole) may increase plasma concentrations of the active metabolite sirolimus. Avoid concomitant use if possible. If required, consider a dose reduction of temsirolimus to 12.5 mg/week and monitor closely for acute toxicity. If the strong inhibitor is discontinued, a washout period of approximately 1 week should be allowed before adjusting the temsirolimus dose upward to the indicated dose; see Dose Adjustments. ■ **Grapefruit juice** may increase plasma concentrations of sirolimus (a major metabolite of temsirolimus) and should be avoided. ■ **CYP3A4/5 inducers** (e.g., carbamazepine, dexamethasone, phenobarbital, phenytoin, rifabutin, rifampin) may decrease plasma concentrations of the active metabolite sirolimus, thus decreasing effectiveness. Avoid concomitant use if possible. If required, consider a dose increase to 50 mg/week. If the strong inducer is discontinued, the temsirolimus dose should be returned to the dose used before initiating the strong CYP3A4 inducer; see Dose Adjustments. ■ Angioedema has been reported in patients taking **mammalian target of rapamycin (mTOR) inhibitors** such as temsirolimus in combination with **ACE inhibitors** (e.g., ramipril) or **calcium channel blockers** (e.g., amlodipine). ■ **St. John's wort** may decrease temsirolimus plasma concentrations, decreasing effectiveness. Avoid use. ■ Use caution with other **drugs that inhibit the efflux transporter P-glycoprotein (P-gp, ABCB1)** (e.g., protease inhibitors [e.g., nelfinavir]); may increase concentrations of temsirolimus. ■ Temsirolimus inhibits P-gp in vitro. Coadministration with drugs that are substrates of P-gp may result in increased concentration of substrates. No clinically significant effect is anticipated when coadministered with agents that are metabolized with CYP2D6 or CYP3A. ■ The combination of **sunitinib** (Sutent) and temsirolimus resulted in dose-limiting toxicity. ■ Do not administer **live virus vaccines** to patients receiving temsirolimus, and avoid close contact with those who have received live virus vaccines. ■ No clinically significant effect is anticipated when temsirolimus is coadministered with agents that are metabolized by CYP2D6 or CYP3A4.

SIDE EFFECTS

The most common side effects include anemia, anorexia, asthenia, edema, elevated alkaline phosphatase and AST, elevated SCr, hyperglycemia, hyperlipidemia, hypertriglyceridemia, hypophosphatemia, leukopenia, lymphopenia, mucositis, nausea, rash, and thrombocytopenia. Other reported side effects include abdominal pain, acne, angioneurotic edema–type reactions, arthralgia, back pain, chest pain, chills, conjunctivitis (including lacrimation disorder), constipation, convulsions, cough, depression, diarrhea, diabetes mellitus, dry skin, dysgeusia, dyspnea, edema, epistaxis, fever, headache, hemorrhage (GI, rectal), hypokalemia, increased bilirubin, increased total cholesterol, increased triglycerides, insomnia, myalgia, nail disorder, neutropenia, pain, pericardial effusion, pharyngitis, pleural effusion, pneumonitis, pruritus, rash, rhinitis, thrombophlebitis, urinary tract infections, vomiting, and weight loss. The most serious side effects include bowel perforation, hyperglycemia/glucose intolerance, hyperlipemia, hypersensitivity reactions, hypertension, infection (pneumonia, URI, wound [including postoperative] sepsis), interstitial lung disease, intracerebral hemorrhage, renal failure, venous thromboembolism (including DVT and pulmonary embolus [including fatal outcomes]), and wound healing complications.

Post-Marketing:

Angioedema, cholecystitis, cholelithiasis, complex regional pain syndrome (reflex sympathetic dystrophy); extravasation with erythema, pain, pancreatitis, swelling, and warmth; injection site reactions; rhabdomyolysis; Stevens-Johnson syndrome.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. Monitor patient closely. Discontinue temsirolimus at the first sign of a hypersensitivity reaction. Monitor patient for 30 to 60 minutes. Treatment may be resumed at the discretion of the physician; see Monitor. Treat severe hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate), and pressor amines (e.g., dopamine). Treat the development of interstitial lung disease as indicated. May require discontinuation of temsirolimus and/or treatment with corticosteroids and/or antibiotics. Some patients have been able to continue therapy without additional intervention. Discontinue in patients who develop nephrotic syndrome.

TENECTEPLASE

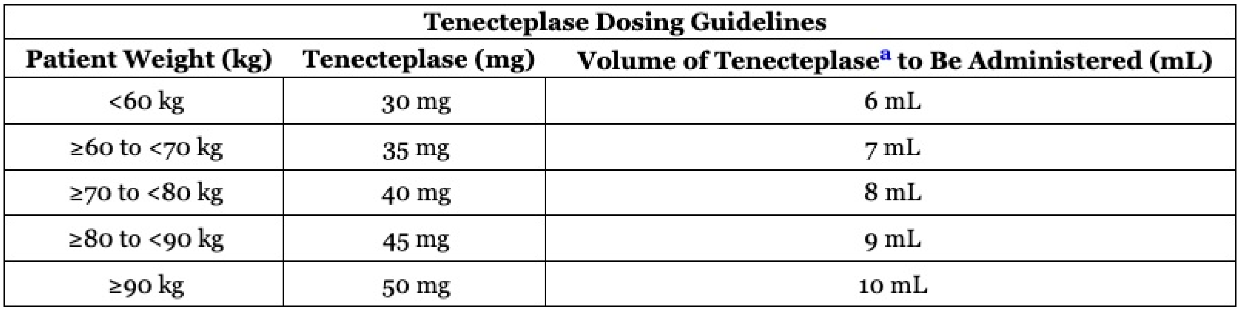
(teh-**NECK**-teh-plays)
TNKase
Thrombolytic agent (recombinant)
pH 7.3

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Initiate therapy as soon as possible after the onset of acute myocardial infarction (AMI) symptoms. Total dose is based on patient weight and should not exceed 50 mg. See the following chart.



Tenecteplase Dosing Guidelines

Patient Weight (kg)	Tenecteplase (mg)	Volume of Tenecteplase[a] to Be Administered (mL)
<60 kg	30 mg	6 mL
≥60 to <70 kg	35 mg	7 mL
≥70 to <80 kg	40 mg	8 mL
≥80 to <90 kg	45 mg	9 mL
≥90 kg	50 mg	10 mL

[a] From one vial of tenecteplase reconstituted with 10 mL of SWFI.

Concurrent administration of heparin and aspirin has been used in MI patients receiving tenecteplase therapy.

See most current guidelines for recommended doses of heparin and aspirin.

DOSE ADJUSTMENTS

None noted.

DILUTION

Remove the shield assembly from the manufacturer-supplied B-D® 10-mL syringe with TwinPak™ dual Cannula Device. Aseptically withdraw 10 mL of SWFI from the supplied diluent vial using the red hub cannula syringe filling device. Do not use bacteriostatic water for injection. Do not discard the shield assembly. Inject the 10 mL of SWFI into the tenecteplase vial, directing the diluent stream into the powder. Slight foaming may occur. Allow product to stand for several minutes. Gently swirl until contents are completely dissolved. Do not shake. The reconstituted preparation is colorless to pale yellow and contains tenecteplase 50 mg/10 mL. Withdraw the desired dose from the vial using the syringe. Once the appropriate dose is drawn into the syringe, stand the shield vertically on a flat surface with the green side down and passively recap the red hub cannula. Remove the entire shield assembly, including the red hub cannula, by twisting counterclockwise. **Note:** The shield assembly also contains the clear-ended blunt plastic cannula; retain for split septum IV access. The supplied syringe is **compatible** with a conventional needle and with needleless IV systems. See package insert for complete instructions for administration.

Storage:

Store unopened vial at CRT or under refrigeration (at 2° to 8° C [(36° to 46° F]). Reconstitution immediately before use preferred, or may be refrigerated for up to 8 hours.

COMPATIBILITY

Manufacturer states, “Precipitation may occur when tenecteplase is administered in an IV line containing dextrose. Dextrose-containing lines should be flushed with a saline-containing solution prior to and following single bolus administration of tenecteplase.”

RATE OF ADMINISTRATION

A single bolus dose over 5 seconds. Flush line with saline-containing solution to ensure delivery of entire dose.

ACTIONS

A tissue plasminogen activator and enzyme produced by recombinant DNA technology. Binds to fibrin in a thrombus and converts plasminogen to plasmin. This initiates local fibrinolysis and dissolution of the clot. Onset of action is prompt. Cleared via hepatic metabolism. Terminal half-life is 90 to 130 minutes.

INDICATIONS AND USES

For use in the reduction of mortality associated with acute myocardial infarction (AMI). Treatment should be initiated as soon as possible after the onset of AMI symptoms.

CONTRAINDICATIONS

Active internal bleeding, history of cerebrovascular accident, intracranial or intraspinal surgery or trauma within the past 2 months, intracranial neoplasm, arteriovenous malformation or aneurysm, known bleeding diathesis, and severe uncontrolled hypertension.

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use and with appropriate emergency drugs and diagnostic and laboratory facilities available. ■ The most common complication is bleeding. Bleeding may be internal (involving intracranial or retroperitoneal sites or the GI, GU, or respiratory tracts) or external bleeding, especially at arterial and venous puncture sites. Use extreme care with the patient; avoid IM injections and any trauma to the patient. Avoid invasive procedures (e.g., arterial puncture and venipuncture). If these procedures are absolutely necessary, use precautionary methods. To minimize bleeding from noncompressible sites, avoid internal jugular and subclavian venous punctures. If an arterial puncture is necessary, use an upper extremity vessel that is accessible to manual compression, apply pressure for at least 30 minutes, and monitor the puncture site closely. ■ Use extreme caution in the following situations: recent major surgery (e.g., CABG, organ biopsy, previous puncture of noncompressible vessels), recent trauma, cerebrovascular disease, recent GI or GU bleeding, hypertension (systolic BP at or above 180 and/or diastolic BP at or above 110), high likelihood of left heart thrombus (e.g., mitral stenosis with atrial fibrillation), acute pericarditis, subacute bacterial endocarditis, hemostatic defects (including those secondary to severe hepatic or renal disease), severe hepatic dysfunction, pregnancy or obstetric delivery, diabetic hemorrhagic retinopathy or other hemorrhagic ophthalmic conditions, septic thrombophlebitis or occluded AV cannula at a seriously infected site, advanced age, patients currently receiving oral anticoagulants (e.g., warfarin), recent administration of GPIIb/IIIa inhibitors (e.g., eptifibatide), or any other condition in which bleeding constitutes a significant hazard or would be particularly difficult to manage because of its location. In the presence of any of these situations, the risk versus benefit of tenecteplase therapy must be evaluated. ■ The use of thrombolytics can increase the risk of thromboembolic events in patients with high likelihood of left heart thrombus, such as patients with mitral stenosis or atrial fibrillation. ■ Cholesterol embolism has been reported rarely in patients treated with all types of thrombolytic agents. See Side Effects. ■ Reperfusion arrhythmias (e.g., sinus bradycardia, accelerated idioventricular rhythm, ventricular premature depolarization, ventricular tachycardia) may occur following coronary thrombolysis. Manage with standard antiarrhythmic measures. Have antiarrhythmic medications readily available. ■ Physicians should choose either thrombolysis or PCI as the primary treatment strategy for reperfusion in patients with large ST-segment elevation myocardial infarctions. Rescue PCI or subsequent elective PCI may be performed after administration of thrombolytic therapies if medically appropriate; however, the optimal use of adjunctive antithrombotic and antiplatelet therapies in this setting is unknown.

■ Standard management of MI should be implemented concomitantly with tenecteplase therapy. Simultaneous therapy with heparin and aspirin is used to reduce the risk of rethrombosis. Increases risk of bleeding; see Usual Dose. ■ Readministration of tenecteplase to patients who have received prior plasminogen activator therapy has not been studied. Use caution if deemed necessary, and monitor for signs of hypersensitivity or anaphylactic reactions. ■ Hypersensitivity reactions have been reported.

Monitor:

Obtain appropriate clotting studies (e.g., PT, PTT, aPTT, fibrinogen levels), CBC, and platelet count. ■ Diagnosis-specific baseline studies (e.g., ECG, troponin) are indicated. Baseline assessment (patient condition, pain, hematomas, petechiae, or recent wounds) should be completed before administration. ■ Type and cross-match may also be ordered. ■ Maintain strict bed rest; monitor the patient carefully and frequently for pain and signs of bleeding; observe catheter sites and apply pressure dressings to any recently invaded site; watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, muscle weakness; and perform frequent neuro checks. Continue until normal clotting function returns. ■ Monitor vital signs and ECG. ■ Monitor for S/S of a hypersensitivity reaction during and for several hours after administration (e.g., anaphylaxis, angioedema, laryngeal edema, rash, and urticaria). ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Compliance with all measures to minimize bleeding (e.g., strict bed rest) is very important. ■ Avoid use of razors, toothbrushes, and other sharp items. Use caution while moving to avoid excessive bumping. ■ Report all episodes of bleeding and apply local pressure if indicated. Expect oozing from IV sites.

Maternal/Child:

Safety for use in pregnancy, breast-feeding and pediatric patients not established. Use in pregnancy only if the potential benefits justify the potential risk to the fetus.

Elderly:

In clinical studies, 30-day mortality rates and incidence of adverse events (e.g., intracranial hemorrhage, stroke, major bleeds) were higher in elderly patients. In elderly patients, the benefits of tenecteplase on mortality should be weighed against the risk of increased adverse events, including bleeding.

DRUG/LAB INTERACTIONS

Formal studies have not been performed. ■ Risk of bleeding may be increased by **any medicine that affects blood clotting,** including anticoagulants (e.g., heparin, warfarin); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel, dipyridamole, glycoprotein GPIIb/IIIa receptor antagonists [e.g., eptifibatide, tirofiban]). Concurrent use not recommended with the exception of heparin and aspirin to reduce the risk of rethrombosis. If concurrent or subsequent use indicated (e.g., management of acute coronary syndrome, percutaneous coronary intervention), monitor coagulation studies closely. ■ Use caution with **any**

medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs, valproic acid). ■ **Coagulation test and/or measures of fibrinolytic activity** may be unreliable unless specific procedures are used to prevent in vitro artifacts; notify the lab of tenecteplase use.

SIDE EFFECTS

Bleeding is the most common adverse reaction: internal (GI tract, GU tract, retroperitoneal, or intracranial), epistaxis, gingival bleeding, hematoma, and superficial or surface bleeding (venous cutdowns, arterial punctures, sites of recent surgical intervention). Hypersensitivity reactions (e.g., anaphylaxis, angioedema, laryngeal edema, rash, and urticaria) have been reported rarely. Fever, hypotension, nausea and vomiting, and reperfusion arrhythmias have occurred. Cholesterol embolization can occur with thrombolytic therapy, but has been reported rarely. Clinical features may include livedo reticularis; “purple toe” syndrome; acute renal failure; gangrenous digits; hypertension; pancreatitis; MI; cerebral, spinal cord, or bowel infarction; retinal artery occlusion; and rhabdomyolysis. Several other adverse events have been reported. These reactions are frequently sequelae of the underlying disease, and the effect of tenecteplase on the incidence of these events is unknown.

ANTIDOTE

Notify physician of all side effects. Note even the most minute bleeding tendency. Oozing at IV sites is expected. Control minor bleeding by local pressure. For severe bleeding in a critical location or suspected intracranial bleeding, discontinue any heparin or antiplatelet therapy immediately. Draw blood for type and cross-match and transfuse as indicated. Consider administration of protamine if heparin has been used. Treat reperfusion arrhythmias with standard antiarrhythmic therapy. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary.

TENIPOSIDE BBW

(teh-**NIP**-ah-side)
VM-26, Vumon
Antineoplastic (mitotic inhibitor)
pH 5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Adults:

All indications and doses are unlabeled.

Acute lymphoblastic leukemia:

165 mg/M² by IV infusion on Days 1, 4, 8, and 11 during consolidation on the "Linker" regimen.

Refractory non-Hodgkin lymphoma:

Given as an IV infusion. Dosage schedules include 30 mg/M² for 10 days or 50 to 100 mg/M² weekly as a single agent; or 60 to 70 mg/M² weekly in combination with other chemotherapy agents.

PEDIATRIC DOSE

See Precautions and Maternal/Child. Optimum dose not established.

Acute lymphocytic leukemia (ALL):

165 mg/M² in combination with cytarabine 300 mg/M². Both drugs are given twice weekly for 8 to 9 doses. An alternate regimen includes teniposide 250 mg/M² and vincristine 1.5 mg/M² once each week for 4 to 8 weeks plus prednisone 40 mg/M² PO daily for 28 days.

DOSE ADJUSTMENTS

Reduce dose by one-half in patients with Down's syndrome and leukemia (increased sensitivity to myelosuppressive chemotherapy). Higher doses may be used in subsequent courses based on degree of myelosuppression and mucositis. Must be individualized. ■ Reduced dose may be necessary in severe renal or hepatic impairment.

DILUTION

Specific techniques required; see Precautions. Must be diluted and given as an infusion. May leach the toxic plasticizer DEHP from PVC infusion bags or sets; prepare and store in bottles (glass, polypropylene) or plastic bags (polypropylene, polyolefin) and administer through polyethylene-lined administration sets (e.g., lipid administration sets or low DEHP–containing nitroglycerin IV sets). Undiluted teniposide has caused acrylic or ABS plastic devices to crack and leak; handle carefully during dilution process. **Compatible** with NS or D5W. Final concentration of 0.1, 0.2, 0.4, or 1 mg/mL desired. Contains 10 mg/mL. 100 mg (10 mL) in 990 mL yields 0.1 mg/mL, in 490 mL yields 0.2 mg/mL, in 240 mL yields 0.4 mg/mL, in 90 mL yields 1 mg/mL. Precipitation may occur at recommended concentrations, especially with excessive agitation. Avoid contact of diluted solution with any other drugs or fluids; flush IV line with D5W or NS before and after administration.

Storage:

Refrigerate unopened ampules in original packaging. Do not refrigerate diluted solutions; 1 mg/mL should be administered within 4 hours; all other dilutions are stable at RT for up to 24 hours.

COMPATIBILITY

Manufacturer states, “Heparin solution can cause precipitation of teniposide; flush IV line thoroughly with D5W or NS before and after administration of teniposide. Because of potential for precipitation, **compatibility** with other drugs, infusion materials, or IV pumps cannot be ensured.” See Dilution, Rate of Administration, and Precautions/Monitor.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Total desired dose, properly diluted and evenly distributed over at least 30 to 60 minutes. Infusion time may be extended. Flush IV line with D5W or NS before and after administration to avoid precipitation of teniposide in IV catheter. Rapid infusion may cause marked hypotension or increased nausea and vomiting.

ACTIONS

An antineoplastic agent. A semi-synthetic derivative of podophyllotoxin related to etoposide. Cell cycle–specific for the late S or early G_2 phase, thus preventing cells from entering mitosis. Cytotoxic effects are related to the relative number of single- and double-strand DNA breaks produced in cells. Has a broad spectrum of in vivo antitumor activity against murine tumors, including hematologic malignancies and various solid tumors. Active against certain murine leukemias with acquired resistance to cisplatin, doxorubicin, amsacrine, daunorubicin, mitoxantrone, or vincristine. Highly protein bound; limits distribution within the body (a beneficial effect). Plasma levels increase with dose. Terminal half-life is 5 hours. Metabolized primarily in the liver. Only about 10% excreted as unchanged drug in urine.

INDICATIONS AND USES

Induction therapy in refractory childhood acute lymphoblastic leukemia. Used in combination with other antineoplastic agents.

Unlabeled uses:

Has been used as an unlabeled agent in several adult protocols (e.g., refractory non-Hodgkin lymphoma and neuroblastoma).

CONTRAINDICATIONS

Hypersensitivity to teniposide, etoposide (no cross-sensitivity to date), or a history of prior severe hypersensitivity reactions to other drugs formulated in Cremophor EL (e.g., cyclosporine, paclitaxel).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. Always wear impervious gloves when handling ampules containing teniposide. After contact with skin, wash immediately and thoroughly with soap and water; after contact with mucous membranes, flush immediately and thoroughly with water. ■ Usually administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be readily available. ■ May cause severe myelosuppression with resulting infection or bleeding. ■ Causes severe myelosuppression when used in combination with other chemotherapeutic agents. Sepsis, sometimes fatal, may result. ■ Use caution in patients with impaired hepatic or renal function; may reduce plasma clearance and increase toxicity. ■ Hypersensitivity reactions, including anaphylaxis, may occur with initial dosing or with repeated exposure. ■ Incidence of hypersensitivity may be increased in patients with brain tumors or neuroblastoma. ■ Acute CNS depression, hypotension, and metabolic acidosis occurred in patients receiving high-dose teniposide pretreated with antiemetic drugs; use caution. ■ Pediatric patients with ALL in remission on teniposide maintenance therapy have shown an increased risk of developing secondary acute nonlymphocytic leukemia (ANLL). ■ Reduce dose in patients with Down syndrome. ■ See Drug/Lab Interactions.

Monitor:

Bone marrow suppression; occurs early with indicated doses and can be profound. Obtain baseline hemoglobin, WBC count with differential, and platelet count. Monitor frequently during therapy, before each dose, and after therapy. See Dose Adjustments. ■ Severe hypersensitivity reactions can occur with teniposide and may be life threatening. Epinephrine, oxygen, and other emergency supplies must be at the bedside. Monitor patient continuously and take vital signs very frequently during the first hour and at intervals thereafter. ■ Monitor renal and hepatic function tests before and during therapy. ■ Determine absolute patency and quality of vein and adequate circulation of extremity. Avoid extravasation; can cause local tissue necrosis and thrombophlebitis. ■ Precipitation sufficient to occlude central venous access catheters has occurred; monitor infusion closely, and flush thoroughly before and after administration. ■ Use prophylactic antiemetics to increase patient comfort. ■ Steady-state volume of distribution increases with a decrease in plasma albumin levels; monitor pediatric patients with hypoalbuminemia carefully. ■ If severe myelosuppression occurs, bone marrow examination should be repeated before a decision to continue therapy is made. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient.

Patient Education:

Report IV site burning or stinging promptly. ■ Avoid pregnancy; effective birth control recommended for males and females. ■ Males should consider the possibility of storing sperm for future artificial insemination. ■ Report any signs of hypersensitivity promptly (e.g., chills, difficult breathing, fever, flushing, rapid heartbeat, rash). ■ Secondary acute nonlymphocytic leukemia (ANLL) has been reported (see Precautions). ■ Interacts with many medications. Discuss all drugs (prescription or nonprescription) with doctor or pharmacist. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: avoid pregnancy. May cause fetal harm; see Patient Education. ■ Potential for serious adverse reactions in nursing infants; discontinue breast-feeding. ■ Contains benzyl alcohol; not recommended for use in premature infants. ■ Intended for use in pediatric patients, but see Precautions/Monitor. ■ When used as a single agent, side effects in pediatric patients from 2 weeks to 20 years of age are similar to other age-groups.

Elderly:

Monitor renal, hepatic, and hematologic function closely.

DRUG/LAB INTERACTIONS

Concomitant use with **vincristine sulfate** has resulted in neurotoxicity, including severe cases of neuropathy. ■ **Sodium salicylate, sulfamethizole, and tolbutamide** displace teniposide from protein-binding sites. Can cause substantial increases in free drug levels and increase toxicity of teniposide. ■ May result in clinically significant drug interactions with **other drugs highly bound to protein** (e.g., buprenorphine, calcium channel blocking agents, phenothiazines). ■ May increase plasma clearance and increase intracellular levels of **methotrexate.** ■ **Phenobarbital, fosphenytoin**, **and phenytoin** increase clearance of teniposide; may reduce effectiveness. ■ Depressant and hypotensive effects of **antiemetics** may be additive with alcohol in teniposide. ■ May cause additive effects with **bone marrow–suppressing agents or agents that cause blood dyscrasias** (e.g., amphotericin B, antithyroid agents [methimazole], azathioprine, chloramphenicol, ganciclovir, interferon, plicamycin, zidovudine) **and radiation therapy.** ■ Do not administer **live virus vaccines.**

SIDE EFFECTS

Most are reversible if detected early. Hypersensitivity reactions (e.g., bronchospasm, chills, confusion, dyspnea, facial flushing, fever, headache, hypertension, hypotension, tachycardia, urticaria) have occurred and can be fatal if not treated promptly. Myelosuppression (anemia, leukopenia, neutropenia, thrombocytopenia) occurs early, can be profound, and recovery can be delayed. Alopecia, asthenia, bleeding, diarrhea, fever, hypotension/cardiovascular, infection, mucositis, nausea and vomiting, rash, thrombophlebitis. Hepatic dysfunctions, metabolic abnormalities, neurotoxicity, and renal dysfunction have occurred in fewer than 1% of patients.

Overdose:

Acute CNS depression, hypotension, and metabolic acidosis.

ANTIDOTE

Keep physician informed of all side effects. Symptomatic treatment is often indicated. Discontinue teniposide and treat hypersensitivity reactions immediately (epinephrine, antihistamines [e.g., diphenhydramine], cimetidine, corticosteroids [e.g., dexamethasone], bronchodilators [e.g., theophylline], IV fluids). Consider risk/benefit before rechallenging any patient who has had a severe hypersensitivity reaction. Pretreatment with corticosteroids and antihistamines and constant observation are imperative. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Consider diazepam or phenytoin for seizures. Hypotension is usually due to a rapid infusion rate; discontinue temporarily. Trendelenburg position and IV fluids should reverse the hypotension; vasopressors (e.g., dopamine) may be required. In addition to antiemetics (e.g., ondansetron), rate reduction may reduce nausea and vomiting. For extravasation, discontinue the drug immediately and administer into another site. Resuscitate as necessary.

TEPROTUMUMAB-trbw

(**TEP**-roe-**TOOM**-ue-mab)
Tepezza
Insulin-like growth factor-1 receptor inhibitor (IGF-1R)
Monoclonal antibody
pH 5.5

USUAL DOSE

Pretreatment:

Verify pregnancy status.

Teprotumumab-trbw:

An initial dose of 10 mg/kg as an IV infusion. Follow with 20 mg/kg every 3 weeks for 7 additional infusions.

DOSE ADJUSTMENTS

No dose adjustments indicated based on age (18 to 80 years), sex, race/ethnicity, weight, mild to moderate renal impairment (CrCl 30 to 89 mL/min), bilirubin levels (2.7 to 24.3 mcmol/L), or AST or ALT levels. ■ The effect of hepatic impairment on its pharmacokinetics is unknown.

DILUTION

Available as a white to off-white lyophilized powder in 500-mg single-dose vials. Calculate the dose (mg) and determine the number of vials needed for the 10 or 20 mg/kg dose based on patient weight. For example, for a 70-kg patient, a 10 mg/kg initial dose would require 1.4 vials (10 mg/kg × 70 kg = 700 mg ÷ 500 mg/vial = 1.4 vials, so 2 vials would be needed). Reconstitute each vial with 10 mL SWFI. Direct the stream of diluent towards the wall of the vial, not toward the lyophilized powder. ***Do not shake.*** Gently swirl the solution by rotating the vial until the lyophilized powder is dissolved.

The reconstituted solution has a volume of 10.5 mL. Withdraw 10.5 mL of reconstituted solution to obtain 500 mg. Final concentration is 47.6 mg/mL. Teprotumumab-trbw must be further diluted. Using a 100-mL or 250-mL infusion bag of NS, withdraw an amount of NS equal to the amount of teprotumumab-trbw to be added (1.4 vials or 14.7 mL [700 mg] in the provided example). Next inject the desired dose (14.7 mL) into the NS. Use a 100-mL bag of NS for doses less than 1800 mg and a 250-mL bag of NS for doses of 1800 mg or more. Mix diluted solution by gentle inversion. ***Do not shake.***

Filters:

Specific information not available.

Storage:

Refrigerate at 2° to 8° C (36° to 46° F) in original carton until time of use to protect from light. ***Do not freeze.*** Combined storage time of reconstituted and fully diluted solution is a total of 4 hours at 20° to 25° C (68° to 77° F) or up to 48 hours if refrigerated. Protect from light and bring to RT before infusion if refrigerated. ***Do not freeze reconstituted or diluted solution.*** Discard vial(s) and all unused contents.

COMPATIBILITY

Manufacturer states, “Should not be infused concomitantly with other agents.” No **incompatibilities** with polyethylene (PE), polyvinyl chloride (PVC), polyurethane (PUR), or polyolefin (PO) bags and IV administration sets have been observed.

RATE OF ADMINISTRATION

Do not administer as an IV push or bolus.

A single dose equally distributed as an IV infusion over 90 minutes for the first two infusions. If well tolerated, the minimum time for subsequent infusions can be reduced to 60 minutes. If not well tolerated, the minimum time should remain at 90 minutes.

ACTIONS

Teprotumumab-trbw is an insulin-like growth factor-1 receptor inhibitor (IGF-1R) and a fully human IgG1 monoclonal antibody. Mechanism of action in patients with thyroid eye disease has not been fully characterized. It binds to IGF-1R and blocks its activation and signaling. Metabolism has also not been fully characterized, but it is expected to undergo metabolism via proteolysis. Elimination half-life is approximately 15 to 25 days.

INDICATIONS AND USES

Treatment of thyroid eye disease.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Infusion reactions have been reported in patients treated with teprotumumab-trbw. ■

May cause an exacerbation of pre-existing inflammatory bowel disease (IBD). ■ Hyperglycemia occurred in 10% of patients ($^{2}/_{3}$ of whom had pre-existing diabetes) in clinical trials. Hyperglycemic events should be controlled with medications for glycemic control, if necessary. ■ As with all therapeutic proteins, there is a potential for immunogenicity.

Monitor:

Monitor for S/S of infusion-related reactions (e.g., transient increases in blood pressure, dyspnea, feeling hot, headache, muscular pain, and tachycardia). Infusion reactions may occur during any of the infusions or within 1.5 hours after an infusion. Infusion reactions are usually mild or moderate in severity and can be managed with corticosteroids and antihistamines. In patients who experience an infusion reaction, consider premedicating with an antihistamine, antipyretic, or corticosteroid and/or administering all subsequent infusions at a slower infusion rate. ■ Monitor patients with IBD for flare-up of disease. If IBD exacerbation is suspected, consider discontinuing therapy. ■ Monitor patients for elevated blood glucose and symptoms of hyperglycemia. Patients with pre-existing diabetes should be under appropriate glycemic control before receiving teprotumumab-trbw.

Patient Education:

Effective contraception is required in females of reproductive potential before initiating teprotumumab-trbw, during treatment, and for 6 months after the last dose. ■ Inform health care provider of a known or suspected pregnancy. ■ Promptly report S/S of an infusion reaction (e.g., feeling hot, headache, muscular pain, shortness of breath, and tachycardia). ■ Seek medical advice if diarrhea, with or without blood or rectal bleeding and associated with abdominal pain or cramping/colic, urgency, or incontinence, occurs. ■ Risk of hyperglycemia. If diabetic, discuss adjusting of glycemic control medications, as appropriate.

Maternal/Child:

Based on its mechanism of action inhibiting insulin-like growth factor 1 receptor (IGF-1R), teprotumumab-trbw may cause fetal harm when administered to a pregnant woman. Exposure may lead to increase in fetal loss. ■ No information regarding the presence of teprotumumab-trbw in human milk, the effects on the breast-fed infant, or the effects on milk production. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety or effectiveness observed between patients 65 years of age or older and younger patients (under 65 years of age).

DRUG/LAB INTERACTIONS

No studies evaluating the drug interaction potential have been conducted.

SIDE EFFECTS

Alopecia, diarrhea, dry skin, dysgeusia, fatigue, headache, hearing impairment, hyperglycemia, muscle spasm, and nausea are most common.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Consider discontinuing teprotumumab-trbw if IBD exacerbation is suspected. Infusion reactions are usually mild or moderate in severity and can be managed with corticosteroids and antihistamines. In patients who experience an infusion reaction, consider premedicating with an antihistamine, antipyretic, or corticosteroid and/or administering all subsequent infusions at a slower infusion rate. Hyperglycemic events should be controlled with appropriate medications.

THEOPHYLLINE IN D5W

(thee-**OFF**-ih-lin)
100% Theophylline
Bronchodilator
Respiratory stimulant
pH 3.5 to 6.5

USUAL DOSE

Use caution; this preparation is 100% theophylline, not 79% as in aminophylline.

To obtain maximum benefit with minimal risk of adverse effects, dosing must be individualized based on serum theophylline concentration and patient response.

Monitor frequently to avoid toxicity. All doses are based on lean body weight; theophylline does not distribute into fatty tissue. ***All doses listed are milligrams of theophylline to be administered.***

Bronchodilation in Acute Asthma or Bronchospasm

With an average mean volume of distribution of 0.5 L/kg (range is 0.3 to 0.7 L/kg), each mg/kg of theophylline given over 30 minutes should result in an average 2 mcg/mL increase in serum theophylline concentration.

Adults, children, infants, and neonates who *HAVE NOT* received a theophylline preparation in the previous 24 hours:

An ***initial loading dose*** of 4.6 mg/kg of theophylline should produce a serum concentration of 10 mcg/mL (range 6 to 16 mcg/mL). Measure serum theophylline concentration in 30 minutes to determine whether additional loading doses are indicated. Once a serum concentration of 10 to 15 mcg/mL is obtained with loading dose(s), it should be maintained with a continuous infusion. Rate of infusion is based on the pharmacokinetic parameters (e.g., volume of distribution, clearance, concomitant disease states) of the specific patient population and should achieve a target serum concentration of 10 mcg/mL. See Dose Adjustments and Monitor for recommendations of serum theophylline testing after an infusion is started.

Adults, children, infants, and neonates who *HAVE* received a theophylline

preparation in the previous 24 hours:

A serum theophylline concentration must be obtained before considering any loading dose.

Calculate the appropriate loading dose with the following formula.

$$D = (\text{Desired } C - \text{Measured } C) \times (V)$$

D is the loading dose, C is the serum theophylline concentration, and V is the volume of distribution (0.5 L/kg). Desired serum concentration in this situation should be conservative (e.g., 10 mcg/mL) to allow for variability in the volume of distribution, carefully evaluating the patient condition and risk versus benefit. It is not recommended by the manufacturer, but another source suggests that a smaller loading dose may be considered if it is not immediately possible to obtain a theophylline serum concentration. Carefully evaluate the patient's condition and risk versus benefit. The potential for theophylline toxicity must be ruled out. For example, if significant respiratory distress is present, a smaller loading dose of 2.3 mg/kg should increase the theophylline level by approximately 5 mcg/mL. In the absence of toxicity, this increase is unlikely to cause significant side effects and may improve the clinical picture. In all situations, measure serum theophylline concentration in 30 minutes to determine if additional loading doses are indicated. Once a serum concentration of 10 to 15 mcg/mL is obtained with or without loading dose(s), it should be maintained with a continuous infusion. Rate of infusion is based on the pharmacokinetic parameters (e.g., volume of distribution, clearance, concomitant disease states) of the specific patient population and should achieve a target serum concentration of 10 mcg/mL. See Dose Adjustments and Monitor for recommendations of serum theophylline testing after an infusion is started.

Maintenance infusion:

Desired theophylline serum concentration is 10 mcg/mL. Most maintenance doses can be reduced within the first 12 hours based on serum theophylline levels and depending on patient condition and response; see Dose Adjustments. Because of a large interpatient variability in theophylline clearance, each patient may differ from the mean value used to calculate these infusion rates. Another serum concentration is recommended one expected half-life after starting the continuous infusion (approximately 4 hours in pediatric patients 1 to 9 years of age, and 8 hours in nonsmoking adults) and daily until the infusion is discontinued. See Dose Adjustments.

Theophylline Infusion Rates Following an Appropriate Loading Dose	
Patient Population	**Theophylline Infusion Rate in mg/kg/hr**[a]
Neonates up to 24 days of age	1 mg/kg ***every 12 hours***[b]
Neonates over 24 days of age	1 mg/kg ***every 12 hours***[b]
Infants 6 to 52 weeks of age	mg/kg/hr = 0.008 × age in weeks + 0.21[c]
Children 1 to 9 years	0.8 mg/kg/hr
Children 9 to 12 years	0.7 mg/kg/hr
Adolescent smokers 12 to 16 years	0.7 mg/kg/hr
Adolescent nonsmokers 12 to 16 years	0.5 mg/kg/hr[d]
Adults (healthy nonsmokers 16 to 60 years)	0.4 mg/kg/hr[d]
Elderly over 60 years	0.3 mg/kg/hr[e]
Cardiac decompensation, cor pulmonale, liver dysfunction, sepsis with multi-organ failure, or shock	0.2 mg/kg/hr[e]

[a] Lower initial dose may be required for patients receiving other drugs that decrease theophylline clearance (e.g., cimetidine [Tagamet]).

[b] To achieve a target concentration of 7.5 mcg/mL for neonatal apnea.

[c] See package insert or contact Baxter or Hospira if additional information desired.

[d] Not to exceed 900 mg/day unless serum levels indicate need for a larger dose.

[e] Not to exceed 400 mg/day or 21 mg/hr (17 mg/hr as theophylline) unless serum levels indicate need for a larger dose.

NEONATAL DOSE

Apnea and bradycardia of prematurity (unlabeled):

Aminophylline oral solutions and injection or theophylline oral solutions are preferred. Increased risks and volume of solution with premixed IV solutions are a concern. ***Loading dose:*** 4.6 mg/kg given over 30 minutes. See all criteria under Usual Dose. See Maternal/Child.

Maintenance dose:

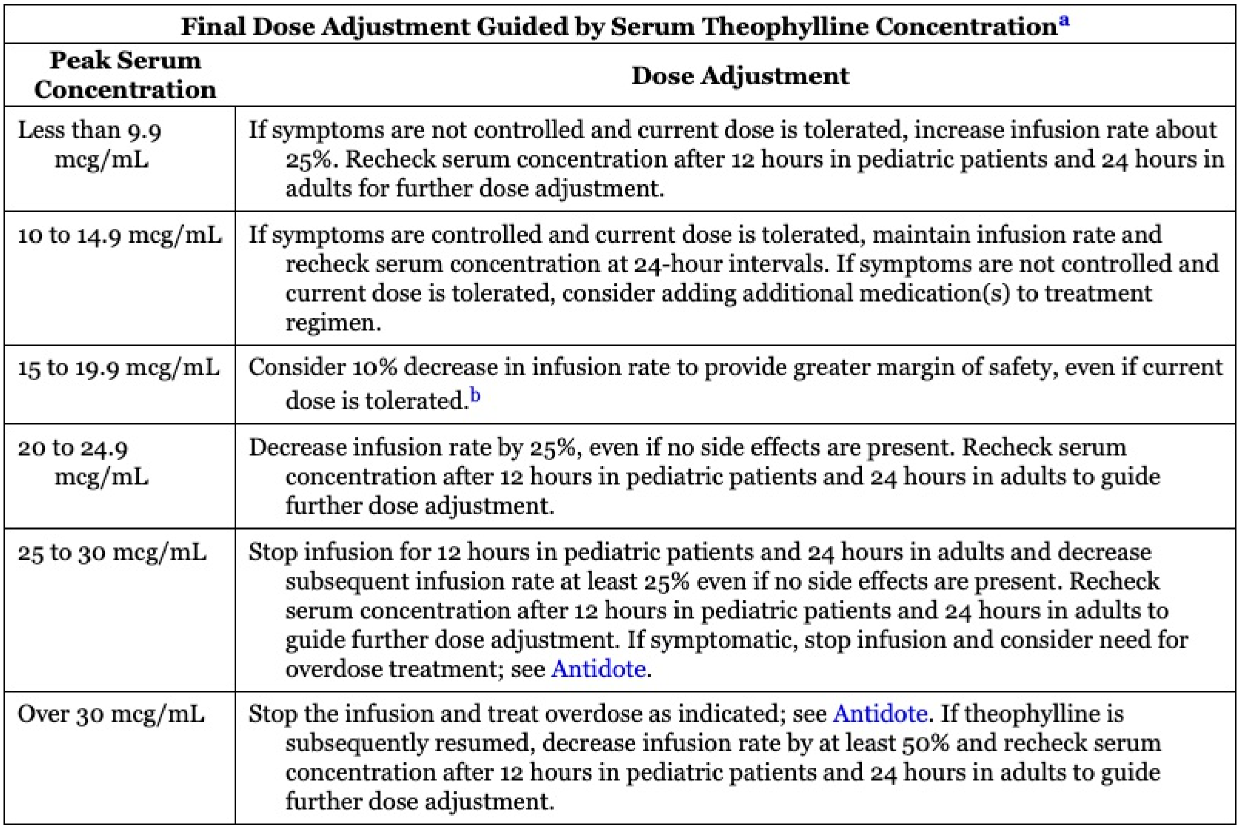
See Maintenance Infusion under Usual Dose. Manufacturer recommends keeping serum theophylline level at 7.5 mcg/mL.

DOSE ADJUSTMENTS

To determine if the concentration is accumulating or declining from the post-loading dose level, a serum concentration is recommended one expected half-life after starting the continuous infusion; see the following chart or see literature for a complete summary. If the level is declining (higher than average clearance), consider an additional loading dose or increasing the infusion rate. If the level is increasing, assume accumulation and decrease the infusion rate before the level exceeds 20 mcg/mL. In patients with reduced protein binding, measurement of unbound serum theophylline concentration provides a more reliable means of dose adjustment than measurement of total serum theophylline concentration. Concentrations of unbound theophylline should be maintained in a range of 6 to 12 mcg/mL.

Theophylline Half-Life (Approximate)	
Age	**Half-Life Mean (Range) in Hours**
Premature neonates, see Maternal/Child	
3 to 15 days	30 (17 to 43)
25 to 57 days	20 (9.4 to 30.6)
Term infants, see Maternal/Child	
1 to 2 days	25.7 (25 to 26.5)
3 to 30 weeks	11 (6 to 29)
Children	
1 to 4 years	3.4 (1.2 to 5.6)
4 to 12 years	Not reported in studies
13 to 15 years	Not reported in studies
6 to 17 years	3.7 (1.5 to 5.9)
Adults (16 to 60 years) and healthy nonsmoking asthmatics	8.7 (6.1 to 12.8)
Elderly (over 60 years); nonsmokers with normal cardiac, liver, and renal function	9.8 (1.6 to 18)

There are huge variances in patients with concurrent illness or altered physiologic states (e.g., acute pulmonary edema, COPD, cystic fibrosis, fever with acute viral respiratory illness in pediatric patients [9 to 15 years], liver disease, pregnancy, sepsis with multi-organ failure, thyroid disease); see package insert. ■ In patients with cor pulmonale, cardiac decompensation, liver dysfunction, or in those taking drugs that markedly reduce theophylline clearance (e.g., cimetidine [Tagamet]), the initial theophylline infusion rate should not exceed 17 mg/hr unless serum concentrations can be monitored every 24 hours. Up to 5 days may be required before steady state is reached in these patients; see Drug/Lab Interactions. ■ Theophylline clearance is increased and half-life decreased by low-carbohydrate/high-protein diets, parenteral nutrition, and daily consumption of charcoalbroiled beef. A high-carbohydrate/low-protein diet can decrease the clearance and prolong the half-life of theophylline. ■ Dose adjustments based on gender are not required; race has not been studied. ■ To decrease the risk of side effects associated with unexpected large increases in serum theophylline concentration, dose adjustment recommendations included in the following chart should be considered as the upper limit.



Final Dose Adjustment Guided by Serum Theophylline Concentration[a]	
Peak Serum Concentration	**Dose Adjustment**
Less than 9.9 mcg/mL	If symptoms are not controlled and current dose is tolerated, increase infusion rate about 25%. Recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults for further dose adjustment.
10 to 14.9 mcg/mL	If symptoms are controlled and current dose is tolerated, maintain infusion rate and recheck serum concentration at 24-hour intervals. If symptoms are not controlled and current dose is tolerated, consider adding additional medication(s) to treatment regimen.
15 to 19.9 mcg/mL	Consider 10% decrease in infusion rate to provide greater margin of safety, even if current dose is tolerated.[b]
20 to 24.9 mcg/mL	Decrease infusion rate by 25%, even if no side effects are present. Recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults to guide further dose adjustment.
25 to 30 mcg/mL	Stop infusion for 12 hours in pediatric patients and 24 hours in adults and decrease subsequent infusion rate at least 25% even if no side effects are present. Recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults to guide further dose adjustment. If symptomatic, stop infusion and consider need for overdose treatment; see Antidote.
Over 30 mcg/mL	Stop the infusion and treat overdose as indicated; see Antidote. If theophylline is subsequently resumed, decrease infusion rate by at least 50% and recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults to guide further dose adjustment.

[a] Dose increases should not be made in patients with an acute exacerbation of symptoms unless the steady-state serum theophylline concentration is less than 10 mcg/mL.

[b] Dose reduction and/or serum theophylline concentration measurement is indicated whenever side effects are present, physiologic abnormalities that can reduce theophylline clearance occur (e.g., sustained fever), or a drug that interacts with theophylline is added or discontinued; see Precautions and Drug/Lab Interactions.

DILUTION

Supplied pre-diluted in flexible plastic containers in various concentrations (0.4 mg/mL to 4 mg/mL) and amounts of D5W (50 mL to 1,000 mL). Follow manufacturer's directions to prepare for infusion. Do not use flexible containers in series connections.

Storage:

Store at 25° C (77° F). Avoid excessive heat; protect from freezing. Exposure to temperatures above 25° C (77° F) may lead to minor losses in moisture content. Discard unused portion if smaller doses are required.

COMPATIBILITY

Manufacturer states, "Do not mix with other drugs" and "Because dosages of theophylline are titrated to response, no additives should be made to theophylline in 5% dextrose." If S/S of theophylline toxicity are present, solutions containing dextrose without electrolytes should not be administered simultaneously with blood through the same infusion set because of the possibility of agglomeration of erythrocytes.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Most references suggest a single dose over a minimum of 30 minutes. Do not exceed an average rate of 25 mg/min. Rapid administration may cause cardiac arrhythmias. Discontinue primary infusion if theophylline administered by piggyback or additive tubing and a possible **incompatibility** problem exists.

Patients over 60 years of age, patients with cor pulmonale, cardiac decompensation, or liver dysfunction, or in those taking drugs that markedly reduce theophylline clearance (e.g., cimetidine [Tagamet]):

Unless serum concentrations can be monitored at 24-hour intervals, the initial rate should not exceed 17 mg/hr. Up to 5 days may be required to reach steady state in these patients.

ACTIONS

An alkaloid xanthine derivative. It relaxes smooth muscle in the airways (bronchodilation) and suppresses the response of the airways to stimuli (non-bronchodilator prophylactic effects). Cardiac output, urinary output, and sodium excretion are increased. The force of contraction of diaphragmatic muscles is increased. Skeletal and cardiac muscles are stimulated, as is the CNS to a lesser degree. There is peripheral vasodilation. It decreases pulmonary artery pressure and lowers the threshold of the respiratory center to CO_2. Well distributed throughout the body. In adults and children over 1 year of age, 90% of a dose is metabolized in the liver. Because of a large interpatient variability in theophylline clearance, half-life varies extensively based on age, concurrent illness, altered physiological state, or coadministration of other drugs; see Dose Adjustments, Precautions, Maternal/Child, and Elderly. Excreted in a changed form in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Adjunct to inhaled beta-2 selective agonists (e.g., albuterol) and systemic corticosteroids for the treatment of acute exacerbations of the symptoms and reversible airflow obstruction associated with asthma and other chronic lung diseases (e.g., emphysema, chronic bronchitis).

Unlabeled uses:

Apnea and bradycardia of prematurity. Aminophylline oral solutions or injection and theophylline oral solutions are preferred. ■ Reduce bronchospasm in cystic fibrosis and acute descending respiratory infections.

CONTRAINDICATIONS

Known sensitivity to theophylline or other product components; known allergy to corn or corn products.

PRECAUTIONS

There is an increase in the volume of distribution of theophylline (primarily due to reduction in plasma protein binding) in premature neonates, patients with hepatic cirrhosis, uncorrected acidemia, the elderly, and women during the third trimester of pregnancy. Toxicity may occur in the therapeutic range. ■ Theophylline clearance may be reduced based on age (e.g., neonates [term and premature], children under 1 year of age, elderly [over 60 years]) and concurrent diseases (e.g., infants under 3 months of age with reduced renal function; patients with acute pulmonary edema, congestive heart failure, cor pulmonale, hypothyroidism, liver disease [e.g., cirrhosis, acute hepatitis], sepsis with multi-organ failure, shock; patients with a fever of 102° F or more for 24 hours or more, or lesser temperature elevations for longer periods); in patients who have stopped smoking; and with the addition of drugs that inhibit or enhance theophylline metabolism (see Drug/Lab Interactions). Variances in clearance may be up to 50% or more. Risk of severe toxicity increased in these patient populations; dose reduction and more frequent monitoring may be required. ■ Saliva theophylline concentrations are not reliable for dose adjustment without special techniques. ■ Use with extreme caution in patients with active peptic ulcer disease, cardiac arrhythmias (not including bradyarrhythmias), or seizures; may exacerbate these conditions. ■ IV administration may cause fluid overloading, resulting in dilution of serum electrolyte concentrations, overhydration, congested states, or pulmonary edema. ■ Initiate oral therapy as soon as symptoms are adequately improved. ■ See Maternal/Child and Drug/Lab Interactions.

Monitor:

Monitor serum levels as directed in Usual Dose and Dose Adjustments to achieve maximum benefit with minimum risk. Each 0.5 mg/kg will increase serum theophylline by 1 mcg/mL. 10 mcg/mL to less than 20 mcg/mL is considered therapeutic. Peak serum level is best measured 20 to 30 minutes after initial loading dose, a half-life after the initial infusion, or 12 to 14 hours into continuous infusion. ■ Monitor vital signs, including lung sounds. ■ Monitor for all signs of toxicity; see Side Effects. Serious toxicity may not be preceded by less severe side effects. ■ Serum theophylline measurements are indicated before making a dose increase; whenever signs or symptoms of toxicity are present; whenever a new illness presents, an existing illness worsens, a change in treatment regimen is initiated that may alter theophylline clearance (e.g., sustained fever, hepatitis [see Precautions], or drugs that may interact are added or deleted [see Drug/Lab Interactions]); and every 24 hours throughout the infusion. ■ Stop the IV infusion and obtain a serum theophylline concentration immediately in any patient on theophylline who develops nausea or vomiting (particularly repetitive vomiting) or if any other signs of toxicity occur, even if another cause is suspected. ■ Dose increases should not be made in patients with an acute exacerbation of symptoms unless the steady-state serum theophylline concentration is less than 10 mcg/mL. ■ Patients with a very high initial clearance rate (low steady-state serum theophylline concentrations at above-average doses) are likely to experience large changes in serum concentration in response to dose changes. ■ Maintain hydration. ■

Monitor IV site; changing of IV administration equipment is recommended every 24 hours. ■ See Antidote, Precautions, Maternal/Child, Elderly, and Drug/Lab Interactions.

Patient Education:

Do not take or discontinue any prescription or over-the-counter medication, including herbal products, without physician's approval. ■ Promptly report S/S of toxicity (e.g., nausea and vomiting).

Maternal/Child:

Category C: use in pregnancy only if clearly indicated. Has been associated with fetal harm and malformations in animal studies. Elimination of theophylline is prolonged during the third trimester of pregnancy and may be prolonged in women on the twentieth day of their menstrual cycle. ■ Neonates may have therapeutic blood levels and may develop apnea from theophylline withdrawal. ■ Elimination of drug is prolonged in premature infants, neonates, and children up to 1 year. Use with extreme caution in children. Has caused fatal reactions. ■ Elimination reaches maximum values by 1 year of age, remains fairly constant to 9 years of age, and slowly decreases by approximately 50% to adult values at 16 years of age. ■ Children under the age of 1 year, as well as neonates with decreased renal function, require careful attention to dosing and frequent monitoring of serum theophylline concentrations. ■ Secreted in breast milk; some sources recommend discontinuing breast-feeding. If the decision is made to breast-feed, monitor infant for evidence of side effects.

Elderly:

Compared to healthy young adults, clearance of theophylline is decreased an average of 30% in healthy elderly. Monitor dosing carefully; frequent serum theophylline concentrations are recommended. See Dose Adjustments, Precautions, and Monitor.

DRUG/LAB INTERACTIONS

Review of patient drug profile by pharmacist imperative at time of initiation of aminophylline and with any change in medication regimen. ■ Do not use **one xanthine derivative concurrently with another xanthine derivative, ephedrine, or other sympathomimetic drugs.** ■ Xanthines antagonize or potentiate or are themselves antagonized or potentiated by many drug groups. Monitor serum levels as indicated. Theophylline clearance increased and serum levels decreased by **aminoglutenide, barbiturates, carbamazepine** (Tegretol), **isoproterenol** (Isuprel), **hydantoins** (e.g., phenytoin [Dilantin]), **rifampin** (Rifadin), **smoking, sulfinpyrazone** (Anturane). Theophylline clearance decreased and serum levels increased by **alcohol, allopurinol, beta-adrenergic blockers** (e.g., propranolol), **cimetidine** (Tagamet), **ciprofloxacin** (Cipro IV), **clarithromycin, disulfiram** (Antabuse), **enoxacin** (Penetrex), **erythromycin, estrogen-containing oral contraceptives, fluvoxamine** (Luvox), **interferon alfa-A, methotrexate, exiletine, pentoxifylline** (Trental), **propafenone** (Rythmol), **tacrine** (Cognex), **thiabendazole** (Mintezol), **troleandomycin** (TAO), **verapamil.** ■ Inhibits **pancuronium;** increased doses of pancuronium may be required to achieve neuromuscular blockade. ■ **Carbamazepine** (Tegretol) and **loop diuretics** (e.g., furosemide [Lasix]) may increase or decrease serum levels. ■ Reduces sedative effect of **benzodiazepines** (e.g., diazepam [Valium], midazolam [Versed]) **and of propofol** (Diprivan); increased doses of sedatives may be required. To avoid respiratory depression, reduce sedative dose if theophylline is discontinued or if dose is significantly reduced. ■ May decrease **lithium** levels. Dose adjustment and monitoring of lithium levels may be indicated. ■ Concurrent use with **halothane** may induce cardiac arrhythmias. ■ Concurrent use with **ketamine** may lower theophylline seizure level. ■ Concurrent use with **ephedrine** may increase nausea, nervousness, and insomnia. ■ May increase lab values for **free fatty acids, glucose, HDL, LDL, total cholesterol, uric acid, and urinary free cortisol excretion.** ■ Caffeine and xanthine metabolites in neonates or patients with renal dysfunction may cause readings **from some immunoassay techniques to be higher than the actual serum theophylline concentration.** ■ Interferes with **dipyridamole-assisted MI perfusion studies.** Theophylline blocks **adenosine** receptors; higher doses of adenosine may be required to achieve desired effects. ■ Interactions with other drugs may occur; package insert has a list of drugs documented not to interact with theophylline.

SIDE EFFECTS

Headache, insomnia, nausea, vomiting most common when peak serum concentrations are less than 20 mcg/mL. Rarely a severe allergic reaction of the skin (e.g., exfoliative dermatitis) may occur. Toxicity resulting in death may occur suddenly at levels less than

20 mcg/mL, especially in certain populations (see Precautions); may occur more frequently with serum levels above 20 mcg/mL. Anxiety, arrhythmias (e.g., atrial fibrillation, tachycardia, ventricular fibrillation), cardiac arrest, convulsions, delirium, dizziness, flushing, hyperpyrexia, intractable seizures, nausea, peripheral vascular collapse, persistent vomiting, restlessness, temporary hypotension. Reactions associated with the infusion may include extravasation, febrile response, hypervolemia, injection site infection, and venous thrombosis or phlebitis.

Post-Marketing:

Hypercalcemia was reported in a patient with hyperthyroid disease at therapeutic theophylline concentrations.

Overdose:

Acute: Acid/base disturbances, arrhythmias (e.g., sinus tachycardia), hyperglycemia, hypokalemia, seizures (usually with serum concentrations over 100 mcg/mL), vomiting, and death have occurred. ***Chronic:*** All of the above plus various arrhythmias, seizures (with serum concentration greater than 30 mcg/mL), and death.

ANTIDOTE

With onset of any side effect, discontinue drug and notify physician. ■ Stop the IV infusion and obtain a serum theophylline concentration immediately in any patient on theophylline who develops nausea or vomiting (particularly repetitive vomiting) or if any other signs of toxicity occur, even if another cause is suspected. ■ For mild symptoms the physician may choose to continue the drug at a decreased dose and rate of administration. All side effects will be treated symptomatically. Maintain adequate ventilation and adequate hydration. ECG monitoring may be indicated. Grand mal seizures may not respond to anticonvulsants, and treatment should be aggressive. Diazepam (Valium) may be most effective. Diazepam 0.1 to 0.2 mg/kg every 1 to 3 minutes until seizures are terminated is recommended. Treat repetitive seizures with a loading dose of phenobarbital 20-mg/kg infused over 30 to 60 minutes. These doses may cause respiratory arrest; provide assisted ventilation. Phenytoin is ineffective. If fluorinated volatile anesthetics for general anesthesia are required, use caution; may sensitize the myocardium and cause arrhythmias; enflurane has been used. The use of neuromuscular blocking agents abolishes the musculoskeletal tremors but does not terminate seizure activity in the brain. Treat atrial arrhythmias with verapamil, ventricular arrhythmias with lidocaine or procainamide. Use dopamine for hypotension. Do not use stimulants. Resuscitate as necessary.

MANUFACTURER’S SPECIFIC RECOMMENDATIONS FOR ACUTE AND CHRONIC OVERDOSE

In all cases of overdose, contact a regional poison control center to obtain updated information and advice on individualizing recommendations.

Acute overdose (e.g., excessive loading dose or excessive infusion rate for less than 24 hours) or chronic overdose (e.g., excessive infusion rate for

more than 24 hours): Serum concentration 20 to 30 mcg/mL:

Stop the infusion, monitor the patient, and obtain a serum theophylline concentration in 2 to 4 hours to ensure that the concentration is decreasing.

Acute overdose with a serum concentration of 30 to 100 mcg/mL or chronic overdose with serum concentrations greater than 30 mcg/mL in patients 60 years of age or older:

Stop the infusion. Administer multiple-dose oral activated charcoal and measures to control emesis. Monitor the patient and obtain serial theophylline concentrations every 2 to 4 hours to determine the effectiveness of therapy and to determine further treatment decisions. Institute extracorporeal removal if emesis, seizures, or cardiac arrhythmias cannot be adequately controlled.

Acute overdose with a serum concentration greater than 100 mcg/mL or chronic overdose with serum concentrations greater than 30 mcg/mL:

Stop the infusion. Consider prophylactic anticonvulsant therapy. Administer multiple-dose oral-activated charcoal and measures to control emesis. Consider extracorporeal removal, even if the patient has not experienced a seizure. Monitor the patient and obtain serial theophylline concentrations every 2 to 4 hours to determine the effectiveness of therapy and to determine further treatment decisions.

Extracorporeal removal:

Weigh risk versus benefits. Charcoal hemoperfusion is the most effective and increases theophylline clearance up to six-fold, but hypotension, hypocalcemia, and platelet consumption and bleeding diatheses may occur. Hemodialysis is about as efficient as multiple-dose oral-activated charcoal and has a lower risk of serious complications. Consider hemodialysis when charcoal hemoperfusion is not feasible and multiple-dose oral-activated charcoal is ineffective because of intractable emesis. Serum theophylline concentrations may rebound 5 to 10 mcg/mL after either treatment is discontinued due to redistribution of theophylline from the tissue compartment. Peritoneal dialysis is ineffective, and exchange transfusions in neonates have been minimally effective.

TERLIPRESSIN

(ter-li-**PRES**-sin)
Terlivaz
Antidiuretic hormone analog; hormone, posterior pituitary

USUAL DOSE

Initial dose:

0.85 mg IV every 6 hours for 3 days

Maintenance dose:

Beginning on day 4, adjust dose based on serum creatinine (SeCr) as follows:

- If SeCr has decreased by greater than or equal to 30% from baseline, continue 0.85 mg IV every 6 hours until 24 hours after patient achieves two consecutive SeCr values of less than or equal to 1.5 mg/dL or for a maximum of 14 days.
- If SeCr has decreased less than 30% from baseline, give 1.7 mg IV every 6 hours; continue until 24 hours after two consecutive SeCr values of less than or equal to 1.5 mg/dL or for a maximum of 14 days
- If SeCr is greater than or equal to baseline, discontinue terlipressin.

PEDIATRIC DOSE

Not established

DOSE ADJUSTMENTS

Renal:

No dosage adjustments are necessary for the initial dosage; subsequent dose adjustments should be determined based on SeCr response starting on day 4 (see dosing above). Patients with SeCr greater than 5 at the time of initiation are unlikely to experience benefit.

Hepatic:

No dosage adjustments are provided by the manufacturer.

Other dosage adjustments:

Fluid overload—Along with reducing fluid administration and judicious use of diuretics, temporarily interrupt, reduce, or stop terlipressin until the patient volume status improves.
Ischemic signs or symptoms—Stop terlipressin with signs of ischemia.
Respiratory effects—Stop terlipressin if patient develops hypoxia or increase in respiratory symptoms.

DILUTION

IV bolus:

Reconstitute each vial with 5 mL normal saline.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than normal saline.

RATE OF ADMINISTRATION

Give via IV bolus slowly over 2 minutes through a peripheral or central line. Flush line after administration.

ACTIONS

Terlipressin is a synthetic vasopressin analog; a majority of activity results from conversion to lysine–vasopressin via slow enzymatic cleavage, producing an extended duration of systemic vasoconstriction. Terlipressin reduces portal pressure and blood flow into portal vessels, increasing effective arterial blood volume and mean arterial pressure, thus increasing blood flow to the kidneys.

INDICATIONS AND USES

Hepatorenal syndrome, to improve kidney function in adults with hepatorenal syndrome with rapid reduction in kidney function

CONTRAINDICATIONS

Patients with ongoing coronary, peripheral, or mesenteric ischemia; hypoxia; or worsening respiratory symptoms.

PRECAUTIONS

Black Box Warning:

Terlipressin may cause serious or fatal respiratory failure. Patients with volume overload or with acute or chronic liver failure grade 3 are at increased risk. Assess oxygenation saturation before beginning. Do not start terlipressin if patient is experiencing hypoxia (SpO_2 less than 90%) until oxygenation levels improve. Monitor patients for hypoxia using continuous pulse oximetry during treatment, and stop terlipressin if SpO_2 decreases below 90%.

Monitor:

Serum creatinine, oxygen saturation (baseline and continuous during therapy); Acute-on Chronic Liver Failure Grade and volume status (baseline and periodically during treatment); signs and symptoms of fluid overload or ischemia.

Patient education:

Notify provider of swelling (fluid overload), any difficulty breathing, chest pain, or any signs of allergic reaction.

Maternal/child:

Terlipressin causes uterine contractions and endometrial ischemia. Based on its mechanism of action and animal data, in utero exposure may cause fetal harm. It is not know if terlipressin is present in breast milk. According to the manufacturer, the decision to breastfeed during therapy should consider risks to infant, the benefits of breastfeeding, and the benefits to treatment for the mother.

Elderly:

No specific recommendations; refer to adult dosing.

DRUG/LAB INTERACTIONS

Drugs that cause bradycardia; certinib, desmopressin, fexinidazole (avoid), fingolimod, ivabradine, lacosamide, midodrine, ozanimod, ponesimod (avoid), siponimod, tofacitinib

SIDE EFFECTS

Abdominal pain, diarrhea, nausea, dyspnea, respiratory failure, bradycardia, ischemia, hypervolemia, sepsis, pleural effusion, gangrene, hyponatremia, headache

ANTIDOTE

There is no antidote; stop terlipressin and treat supportively based on symptoms.

THIAMINE HYDROCHLORIDE

(**THIGH**-ah-min hy-droh-**KLOR**-eyed)
Vitamin B_1
Nutritional supplement (vitamin)
pH 2.5 to 4.5

USUAL DOSE

Transfer to PO doses when practical; see Precautions. Administer before dextrose solutions in the poorly nourished to avoid the development of acute symptoms of thiamine deficiency.

Thiamine deficiency (prophylaxis):

Administered as part of a TPN program and based on individual patient needs (average daily requirement in a normal healthy adult is 1 mg). Average supplementation in TPN is 6 mg/day; may be increased to 25 to 50 mg/day in patients with a history of alcohol abuse. In critically ill adults, an initial dose of up to 100 mg has been used. May be followed with 50 to 100 mg daily until a regular balanced diet can be eaten. IV dextrose solutions or high carbohydrate diets increase thiamine requirements and may worsen symptoms in patients who are thiamine deficient.

Beriberi:

5 to 30 mg IV or IM 3 times daily for up to 2 weeks. Continue PO for 1 month.

Alcohol withdrawal syndrome:

100 mg IV or IM daily for several days. Administer concurrently with IV glucose. Follow with 50 to 100 mg/day PO.

Wernicke’s encephalopathy:

An initial dose of 100 mg IV. Larger doses may be required in the first 24 hours with extreme caution. Follow with 50 to 100 mg daily until a normal diet is resumed.

PEDIATRIC DOSE

Thiamine deficiency (prophylaxis and/or treatment):

Administered as part of a TPN program and based on individual patient needs (average daily requirement in a normal healthy infant or child ranges from 0.2 mg in infants to 0.9 mg in 9- to 13-year-olds). Up to 10 to 25 mg/24 hr may be used in critically ill pediatric patients. See comments under Usual Dose.

Beriberi:

10 to 25 mg/24 hr. Follow with 10 to 50 mg PO daily for 2 weeks, then 5 to 10 mg PO daily for 1 month.

DILUTION

May be given by IV injection or added to most IV solutions and given as an infusion. See chart on inside back cover.

Storage:

Can be refrigerated; protect from freezing and from light.

COMPATIBILITY

Unstable in neutral or alkaline solutions. Do not use in combination with alkaline solutions (e.g., acetates, barbiturates, carbonates, citrates, copper ions). **Incompatible** with solutions containing sulfites and other oxidizing and reducing agents.

RATE OF ADMINISTRATION

100 mg or fraction thereof over 5 minutes. For 100 mg or larger doses, equal distribution over an extended time as an infusion is preferred.

ACTIONS

A water-soluble vitamin, thiamine is necessary to most metabolic processes in humans, especially carbohydrate metabolism. Widely distributed in all body tissues, metabolized in the liver, and excreted in urine.

INDICATIONS AND USES

Prophylaxis or treatment of thiamine deficiency syndromes including beriberi (wet or dry), Wernicke’s encephalopathy, or peripheral neuritis.

CONTRAINDICATIONS

Known hypersensitivity to thiamine hydrochloride.

PRECAUTIONS

Not commonly administered IV; PO or IM is preferred. ■ Rarely used alone, it is more often administered as a multiple B vitamin. ■ In thiamine deficiency, administer thiamine before giving any glucose load to prevent the sudden onset of Wernicke’s encephalopathy or add 100 mg to each of the first few liters of IV fluid to avoid precipitating heart failure. ■ Requirements may be increased in certain conditions (e.g., alcoholism, burns, GI disease, or malabsorption). ■ Supplementation is necessary in patients receiving total parenteral nutrition (usually administered as a multivitamin). ■ S/S of thiamine deficiency (e.g., ataxia, edema, heart failure, neuritis, ocular signs) may respond within hours of thiamine administration and disappear within days. Confusion and psychosis may be slower to respond and may not improve if nerve damage has occurred.

Patient Education:

Dietary consultation indicated to prevent relapse.

Maternal/Child:

Category A: use only if clearly needed. ■ Use caution in breast-feeding.

SIDE EFFECTS

Anaphylaxis and death caused by hypersensitivity reaction can occur with IV administration. Recent studies have shown that hypersensitivity reactions can occur with equal frequency by any route. Incidence after IV administration is less than 0.1%. May increase in frequency with repeat injections. Other reactions include feeling of warmth, nausea, pain, pruritus, sweating, urticaria, and weakness.

ANTIDOTE

Discontinue the drug, treat hypersensitivity reactions or resuscitate as necessary, and notify the physician.

THIOTEPA BBW

(thigh-oh-**TEP**-ah)
Tepadina
Antineoplastic (alkylating agent/nitrosurea)
pH 5.5 to 7.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Adenocarcinoma of the breast or ovary (thiotepa and Tepadina):

0.3 to 0.4 mg/kg every 1 to 4 weeks. Dose must be carefully individualized. A slow response does not necessarily indicate a lack of response. Increasing the frequency of dosing may only increase toxicity. Initially the higher dose in the given range is commonly administered. After maximum benefit is obtained by initial therapy, it is necessary to continue the patient on maintenance therapy (1- to 4-week intervals). The maintenance dose should be adjusted weekly on the basis of pretreatment control blood counts and subsequent blood counts. Maintenance doses should not be administered more frequently than weekly.

PEDIATRIC DOSE

Class 3 beta-thalassemia:

Tepadina:
Two administrations of 5 mg/kg IV approximately 12 hours apart on Day −6 before allogeneic hematopoietic progenitor (stem) cell transplantation (HSCT) in conjunction with high-dose busulfan and cyclophosphamide as outlined in the following chart. See busulfan and cyclophosphamide monographs.

Dosage Regimen for Allogeneic HSCT in Pediatric Patients With Class 3 Beta-Thalassemia											
	Day Before Transplantation										
Treatment	**Day 10**	**Day 9**	**Day 8**	**Day 7**	**Day 6**	**Day 5**	**Day 4**	**Day 3**	**Day 2**	**Day 1**	**Day 0**
Busulfan IV weight-based dose q 6 hr[a]	X X X X	X X X X	X X X X	X X X X							
Tepadina IV 5 mg/kg twice (approximately 12 hours apart)					X X						
Cyclophosphamide IV 40 mg/kg/day						X	X	X	X		
Stem cell infusion											X

[a] **Busulfan IV weight-based dose:** 1 mg/kg q 6 hr for patients less than 9 kg; 1.2 mg/kg q 6 hr for patients 9 to 16 kg; 1.1 mg/kg q 6 hr for patients 16.1 kg to 23 kg; 0.95 mg/kg q 6 hr for patients 23.1 to 34 kg; 0.8 mg/kg q 6 hr for patients more than 34 kg.

DOSE ADJUSTMENTS

Reduce dose or discontinue if WBC or platelet count falls rapidly. ■ To continue optimal effect and to preserve correlation between dose and blood counts, maintenance doses should not be administered more frequently than weekly. ■ ***Thiotepa:*** Usually contraindicated but can be used with extreme caution and in low doses in patients with existing hepatic, renal, or bone marrow damage if benefits outweigh risks and are accompanied by hepatic, renal, and hematopoietic function tests.

DILUTION

Specific techniques required; see Precautions. Each 15-mg vial is reconstituted with 1.5 mL of SWFI (10 mg/mL). Each 100-mg vial is reconstituted with 10 mL of SWFI (10 mg/mL). Mix manually by repeated inversions. A hypotonic solution; further dilute with NS before administration. Must be filtered through a 0.22-micron filter before administration. Final solution should be clear; may occasionally show opalescence. Do not use if hazy or opaque or if a precipitate is present.

Thiotepa:

May then be given through a Y-tube or three-way stopcock of a free-flowing IV infusion.

Tepadina:

Dilute to a final concentration between 0.5 and 1 mg/mL. Use of a central venous catheter is required when used for ***class 3 beta-thalassemia***.

Filters:

Filter through a 0.22-micron filter before administration. See Dilution.

Storage:

Thiotepa:

Must be refrigerated before and after reconstitution. Protect from light at all times. Use reconstituted solution within 8 hours. Use diluted solution immediately. ***Tepadina:*** Refrigerate before and after reconstitution; do not freeze. Use reconstituted solution within 8 hours. After dilution, ***Tepadina*** is stable for 24 hours refrigerated and for 4 hours at RT. Immediate use is preferred.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Thiotepa and Tepadina:

Use of a 0.22-micron filter required.

Adenocarcinoma of the breast or ovary (thiotepa and Tepadina):

A single dose of 0.3 to 0.4 mg/kg by rapid IV administration.

Class 3 beta-thalassemia:

Tepadina:

A single dose in a concentration of 0.5 to 1 mg/mL. Administer through a central venous catheter over 3 hours. Flush catheter with 5 mL of NS before and after infusion.

ACTIONS

An alkylating agent chemically and pharmacologically related to nitrogen mustard. Has antitumor activity and is cell-cycle phase–nonspecific. The radiomimetic action is thought to occur through the release of ethylenimine radicals which, like irradiation, disrupt DNA bonds. Results in inhibition of protein, RNA, and DNA synthesis. It is metabolized extensively in the liver and has one major active metabolite (TEPA). Half-life is 1.4 to 3.7 hours in adults. Some urinary excretion of drug and metabolite.

INDICATIONS AND USES

Tepadina:

To reduce the risk of graft rejection when used in conjunction with high-dose busulfan and cyclophosphamide as a preparative regimen for allogeneic hematopoietic progenitor (stem) cell transplantation (HPSCT) for pediatric patients with class 3 beta-thalassemia.

Thiotepa and Tepadina:

Treatment of adenocarcinoma of the breast and ovary. ■ For controlling intracavitary effusions secondary to diffuse or localized neoplastic diseases of various serosal cavities. ■ Treatment of superficial papillary carcinoma of the urinary bladder.

Thiotepa:

Although now largely superseded by other treatments, thiotepa has been effective against other lymphomas, such as lymphosarcoma and Hodgkin disease.

CONTRAINDICATIONS

Thiotepa and Tepadina:

Known hypersensitivity to thiotepa.

Tepadina:

Concomitant use with live or attenuated vaccines.

Thiotepa:

Hepatic, renal, or bone marrow damage unless need is greater than the risk.

PRECAUTIONS

Thiotepa and Tepadina:

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Can cause fetal harm; see Maternal/Child and Patient Education. ■ Hypersensitivity reactions (including anaphylaxis), laryngeal edema, rash, urticaria, and wheezing have been reported. ■ Some evidence of carcinogenicity; risk of secondary malignancy is increased.

Thiotepa:

Highly toxic to the hematopoietic system. Death from septicemia and hemorrhage has occurred as a direct result of hematopoietic depression. ■ Death has occurred after intravesical administration, caused by bone marrow depression from the systematically absorbed drug. ■ See Dose Adjustments and Side Effects.

Tepadina:

Risk of myelosuppression may be increased during treatment of breast and ovarian cancer if bone marrow is compromised by prior irradiation or chemotherapy.

Tepadina high-dose therapy:

Myelosuppression is profound and occurs in all patients treated with high doses of Tepadina together with other chemotherapy in the preparative regimen for class 3 beta-thalassemia. May cause bone marrow ablation with resulting infection or bleeding. Do not begin the preparative regimen if a stem cell donor is not available. ■ Tepadina or its active metabolites may be excreted in the skin of patients undergoing high-dose therapy. May cause blistering, desquamation, pruritus, skin discoloration, and peeling that may be more severe in the axillae, groin, neck area, skin folds, and under dressings. Skin reactions from accidental exposure may also occur. Wash skin thoroughly with soap and water. Flush mucous membranes. ■ Hepatic veno-occlusive disease may occur with high-dose therapy in conjunction with busulfan and cyclophosphamide. ■ Fatal encephalopathy has occurred in patients treated with high doses of thiotepa. Other CNS toxicities (e.g., amnesia, apathy, coma, confusion, disorientation, drowsiness, forgetfulness, hallucinations, headache, inappropriate behavior, psychomotor retardation, seizures, and somnolence) have occurred.

Monitor:

Thiotepa and Tepadina:

Obtain baseline and weekly CBC and platelet counts during therapy and for at least 3 weeks after therapy has been discontinued. ■ Obtain baseline SCr, BUN, and/or liver function tests in patients with renal or hepatic impairment and monitor during treatment. Patients with CrCl less than 30 mL/min and/or a bilirubin level greater than 1.5 to 3 times the ULN (with any AST) may be at increased risk for toxicity due to accumulation of drug and metabolite. ■ Be alert for signs of bone marrow suppression or infection. Use of prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Prophylactic antiemetics may increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for S/S of hypersensitivity reactions. ■ See Drug/Lab Interactions.

Tepadina high-dose therapy:

Monitor CBC and platelets and provide supportive care until hematopoietic recovery. Monitor for cutaneous toxicity. Change occlusive dressings and clean the covered skin at least twice daily through 48 hours after administration of Tepadina. Change bed sheets daily. ■ Monitor for hepatic veno-occlusive disease by physical examination, serum transaminases, and bilirubin daily through BMT Day +28. ■ Monitor for S/S of CNS toxicity, including intracranial hemorrhage and seizures.

Patient Education:

Verify pregnancy status before initiating therapy. Effective contraception should be used by females during therapy and for 6 months after the final dose. ■ Males should use effective contraception during therapy and for 1 year after the final dose. ■ Male and female fertility may be compromised. May damage spermatozoa and testicular tissue, resulting in possible genetic abnormalities; consider sperm conservation before therapy begins. ■ Promptly report S/S of bleeding (e.g., black stools, bruising, change in urine color, epistaxis), infection (e.g., fever, chills), or suspected pregnancy. ■ Promptly report S/S of hypersensitivity reaction (anaphylaxis, laryngeal edema, rash, urticaria, and wheezing). ■ Pediatric patients receiving high-dose therapy should shower or bathe with water at least twice daily through 48 hours after Tepadina administration. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy. Can cause fetal harm; see Patient Education. Has a mutagenic potential. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established except ***Tepadina*** for prevention of graft rejection in pediatric patients undergoing allogeneic HSCT. Safety and effectiveness of Tepadina in neonates have not been established.

Elderly:

Safety and effectiveness of Tepadina as a preparative regimen before HSCT for patients with class 3 beta-thalassemia have not been established in elderly patients. Clinical studies for this indication did not include subjects 65 years of age and older. For all other indications, studies did not include sufficient numbers of subjects over age 65 years to determine whether elderly subjects respond differently than younger subjects. Differences have not been seen. Dose selection should be cautious, taking into account age-related organ impairment and concomitant disease states or drug therapy.

DRUG/LAB INTERACTIONS

Thiotepa and Tepadina:

Possible pharmacokinetic interactions with any concomitantly administered medications have not been formally investigated. ■ **Other drugs that cause bone marrow suppression** (e.g., amphotericin B [all formulations], ganciclovir [Cytovene]) should be avoided. ■ In vitro studies suggest that thiotepa is metabolized by CYP3A4 and CYP2B6 to its active metabolite TEPA. Avoid coadministration of **strong CYP3A4 inhibitors** (e.g., itraconazole, clarithromycin, ritonavir) and **strong CYP3A4 inducers** (e.g., rifampin, phenytoin). May increase toxicity or reduce efficacy. Consider alternative medications with no or minimal potential to inhibit or induce CYP3A4. If use cannot be avoided, monitor closely for adverse drug reactions. ■ In vitro studies also suggest that thiotepa inhibits CYP2B6; clinical relevance unknown. Inhibition of CYP2B6 may reduce the conversion of **cyclophosphamide** to its active metabolite. Reduction in conversion appears to be sequence dependent, with a greater reduction in the conversion to the active metabolite when thiotepa is administered 1.5 hours before the IV administration of cyclophosphamide compared with administration of thiotepa after IV cyclophosphamide. ■ May potentiate **succinylcholine.** May cause prolonged apnea. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs.

Thiotepa:

Avoid combination, either simultaneously or sequentially, with **cancer chemotherapeutic agents or therapeutic modalities** (e.g., nitrogen mustard, cyclophosphamide, radiation therapy) that have the same mechanism of action. Will increase toxicity without increasing therapeutic benefit. Allow complete recovery verified by WBC count before using a second agent.

SIDE EFFECTS

Thiotepa and Tepadina for treatment of adenocarcinoma of the breast and ovary:

Abdominal pain, alopecia, amenorrhea, anaphylactic shock, anorexia, asthma, blurred vision, conjunctivitis, dermatitis, dizziness, dysuria, fatigue, fever, headache, interference with spermatogenesis, laryngeal edema, nausea, pain at injection site, rash, urinary retention, vomiting, and wheezing. Bone marrow suppression (anemia, leukopenia, thrombocytopenia) may be life threatening, is dose related, and can occur with usual doses.

Tepadina as part of the preparative regimen for class 3 beta-thalassemia:

Anemia; cytomegalovirus infection; diarrhea; elevated ALT, AST, and bilirubin; hematuria; hemorrhage; mucositis; neutropenia; thrombocytopenia; and rash are most common. Serious reactions include acute graft-versus-host disease, CNS toxicity (e.g., seizures), cutaneous toxicity (e.g., blistering, desquamation, peeling, pruritus, skin discoloration), hemorrhage (e.g., GI, intracranial, subarachnoid), hepatic veno-occlusive disease, hypersensitivity (e.g., anaphylaxis, asthma, laryngeal edema, rash, urticaria, wheezing), and infection (pneumonia, pseudomonas).

ANTIDOTE

Minor side effects will be treated symptomatically if necessary. Notify the physician of serious side effects. If platelet count falls below 150,000/mm^3 or WBCs fall below 3,000/mm^3, discontinue use and notify physician. Provide supportive care as needed for myelosuppression (e.g., bleeding, infections, symptomatic anemia, thrombocytopenia) until adequate hematopoietic recovery. Administration of whole blood products (e.g., packed RBCs, platelets, or leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Discontinue the drug for severe or life-threatening CNS toxicity and provide supportive care. Discontinue the drug and treat hypersensitivity reactions as indicated.

TICARCILLIN DISODIUM AND CLAVULANATE POTASSIUM

(tie-kar-**SILL**-in dye-**SO**-dee-um and klav-you-**LAN**-ate poe-**TASS**-ee-um)
Timentin
Antibacterial (extended-spectrum penicillin and β-lactamase inhibitor)

pH 5.5 to 7.5

USUAL DOSE

3.1 Gm of preparation available contains 3 Gm ticarcillin to 0.1 Gm clavulanate. Doses vary depending on the severity of the infection, susceptibility of the organism, and condition of the patient. Dose recommendations are based on the ticarcillin content. Treatment usually continued for 10 to 14 days; may be extended if required. Continue for at least 2 days after signs and symptoms of infection have disappeared.

Systemic and urinary tract infections:

60 kg (130 lb) or more:

3.1 Gm every 4 to 6 hours. Some sources extend interval to 6 to 8 hours.

Under 60 kg:

200 to 300 mg/kg of body weight/24 hr in equally divided doses every 4 to 6 hours (33.3 to 50 mg/kg every 4 hours or 50 to 75 mg/kg every 6 hours).

Moderate gynecologic infections:

200 mg/kg/day in divided doses every 6 hours (50 mg/kg every 6 hours).

Severe gynecologic infections:

300 mg/kg/day in divided doses every 4 hours (50 mg/kg every 4 hours).

Surgical prophylaxis (unlabeled):

3.1 Gm 30 to 60 minutes before start of surgery or as soon as the umbilical cord is clamped in cesarean section. Repeat at 4-hour intervals for 3 doses.

PEDIATRIC DOSE

Dose recommendations are based on the ticarcillin content.

Infants and other pediatric patients 3 months to 12 years of age and less than 60 kg:

50 mg/kg every 6 hours. In serious infections, increase to 50 mg/kg every 4 hours. See Contraindications.

Pediatric patients greater than 60 kg:

3.1 Gm every 6 hours for mild to moderate infections. Increase frequency to every 4 hours for severe infections.

Pediatric patients with cystic fibrosis (unlabeled):

300 to 600 mg/kg/24 hr. Give in equally divided doses every 4 to 6 hours (50 to 100 mg/kg every 4 hours or 75 to 150 mg/kg every 6 hours). Maximum dose is 24 Gm/24 hr.

NEONATAL DOSE

Safety for use in infants under 3 months of age not established but has been used. Base dose on ticarcillin component. See Contraindications.

7 days of age or less and weighing less than 2 kg:
75 mg/kg every 12 hours.

7 days of age or less and weighing 2 kg or more:
75 mg/kg every 8 hours.

Over 7 days of age and weighing less than 1.2 kg:
75 mg/kg every 12 hours.

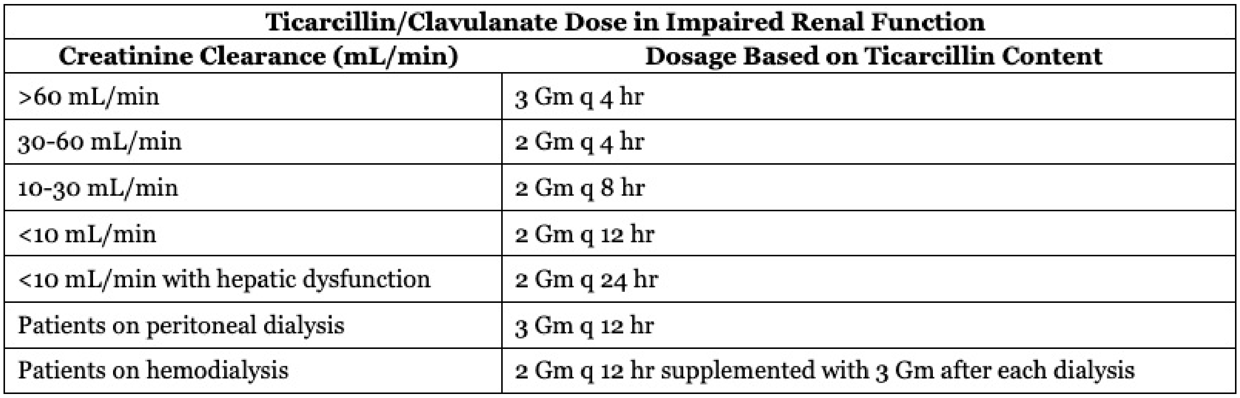
Over 7 days of age and weighing 1.2 to 2 kg:
75 mg/kg every 8 hours.

Over 7 days of age and weighing more than 2 kg:
100 mg/kg every 8 hours.

Term neonate and/or infant under 3 months of age:
50 mg/kg every 4 to 6 hours.

DOSE ADJUSTMENTS

After an initial loading dose of 3.1 Gm, reduce dose in impaired renal function according to the following chart.



Ticarcillin/Clavulanate Dose in Impaired Renal Function

Creatinine Clearance (mL/min)	Dosage Based on Ticarcillin Content
>60 mL/min	3 Gm q 4 hr
30-60 mL/min	2 Gm q 4 hr
10-30 mL/min	2 Gm q 8 hr
<10 mL/min	2 Gm q 12 hr
<10 mL/min with hepatic dysfunction	2 Gm q 24 hr
Patients on peritoneal dialysis	3 Gm q 12 hr
Patients on hemodialysis	2 Gm q 12 hr supplemented with 3 Gm after each dialysis

■ Reduce dose in impaired hepatic function. ■ Reduced dose may be indicated in the elderly.

DILUTION

Each 3.1 Gm or fraction thereof is reconstituted with 13 mL of SWFI or NS (200 mg/mL of ticarcillin). Shake well. A single dose must be further diluted to a final concentration between 10 and 100 mg/mL. Dilute in 50 to 100 mL or more of D5W, NS, or LR and given as an intermittent infusion. Also available prediluted and frozen (Galaxy bags), in

ADD-Vantage vials for use with ADD-Vantage infusion containers, and in pharmacy bulk packages.

Storage:

Store unopened vials at or below 24° C (75° F). Reconstituted solutions (200 mg/mL) and pharmacy bulk packages (300 mg/mL) are stable at room temperature for 6 hours or up to 72 hours under refrigeration (4° C [40° F]). Stability extended after further dilution and with specific diluents (see literature). Store frozen Galaxy containers at or below 20° C (−4° F). Thaw at room temperature or in the refrigerator. Do not force thaw in hot water bath or in microwave. Thawed Galaxy containers are stable for 24 hours at RT or for 7 days refrigerated. Do not refreeze.

COMPATIBILITY

May be inactivated in solution with aminoglycosides (e.g., amikacin, gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. Manufacturer recommends temporarily discontinuing the administration of other solutions at the same site during intermittent infusion and lists as **incompatible** with sodium bicarbonate. See Drug/Lab Interactions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Intermittent infusion:

A single dose over 30 minutes. May be given through Y-tube or three-way stopcock of infusion set. Discontinue primary IV during administration. Too-rapid injection may cause seizures. Slow infusion rate for pain along venipuncture site.

ACTIONS

An extended-spectrum penicillin combined with a β-lactamase inhibitor. Bactericidal for many gram-negative, gram-positive, and anaerobic organisms. Acts by disrupting bacterial cell wall development. This specific formulation extends activity by protecting ticarcillin from degradation by β-lactamase enzymes. Large doses with high blood levels are well tolerated. Widely distributed in body fluids and tissues. Distributes into cerebrospinal fluid only if inflammation is present. Peak serum levels achieved by end of infusion. Half-life is 1.1 hours. Crosses the placental barrier. Primarily excreted in the urine.

INDICATIONS AND USES

Treatment of infections caused by susceptible isolates of specific bacteria in the following conditions caused by β-lactamase–producing organisms: bacterial septicemia; acute and chronic infections of the lower respiratory tract, skin and skin structures, bone and joint, endometrium, and urinary tract; and peritonitis. Useful in mixed infections as presumptive therapy before identifying the causative organism, in infections complicated by impaired renal functions, or in patients receiving immunosuppressive or oncolytic drugs.

Unlabeled use:

Surgical prophylaxis.

CONTRAINDICATIONS

Known history of a hypersensitivity reaction (e.g., anaphylaxis or erythema multiforme) to ticarcillin or other β-lactam antibacterials (e.g., penicillins and cephalosporins [not absolute]); see Precautions.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients undergoing penicillin therapy; most likely to occur in patients with a history of penicillin allergy or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Specific sensitivity studies indicated to determine susceptibility of the causative organism to ticarcillin and clavulanate. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ticarcillin/clavulanate should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Superinfection caused by overgrowth of nonsusceptible organisms can occur. ■ Risk of bleeding associated with abnormalities in coagulation tests have occurred; more likely in patients with renal impairment. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ticarcillin/clavulanate. ■ Seizures have been reported. More common when recommended doses are exceeded, especially in patients with impaired renal function.

Monitor:

Periodic evaluation of renal, hepatic, and hematopoietic systems and serum potassium is recommended. Observe for electrolyte imbalance and cardiac irregularities. Observe for hypokalemia. Monitor serum potassium in patients with fluid and electrolyte imbalance and in patients receiving prolonged therapy. Contains 4.51 mEq sodium/Gm. May aggravate CHF. ■ Observe for increased bleeding tendencies in all patients but especially those with impaired renal function. Monitor coagulation tests as indicated (bleeding time, INR, PT). ■ May cause thrombophlebitis; observe carefully and rotate infusion sites. ■ See Drug/Lab Interactions.

Patient Education:

Report promptly: fever, rash, sore throat, unusual bleeding or bruising, seizures. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ May require alternate birth control.

Maternal/Child:

Category B: use only if clearly needed. Studies in rats have not shown adverse effects on the fetus. ■ Use with caution in breast-feeding. May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ If meningitis is suspected or documented in pediatric patients, an alternative agent should be used; see literature. ■ Safety and effectiveness established for use in pediatric patients between 3 months and 16 years of age. Has been used in infants under 3 months of age but safety for use not established.

Elderly:

Safety and effectiveness similar to that seen in younger adults; however, greater sensitivity of some elderly patients cannot be ruled out. ■ Monitoring of renal function suggested. ■ Use care in dose selection. Consider age-related organ function and concomitant disease or drug therapy; see Dose Adjustments. ■ At the recommended dose, patients may receive 1,285 to 1,927 mg/day (56 to 84 mEq) of sodium. Elderly patients may respond with blunted natriuresis to salt loading. Monitor patients with CHF closely.

DRUG/LAB INTERACTIONS

Probenecid decreases rate of ticarcillin elimination, resulting in higher and more prolonged blood levels of ticarcillin; will not affect clavulanate levels. May be desirable or may cause toxicity. ■ Synergistic when used in combination with **aminoglycosides** (e.g., amikacin, gentamicin). Synergism may be inconsistent; see Compatibility. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Use caution with **anticoagulants** (e.g., heparin), **thrombolytic agents** (e.g., alteplase [tPA]), **platelet aggregation inhibitors** (e.g., aspirin, NSAIDs, dextran, dipyridamole, **glycoprotein GPIIb/IIIa receptor antagonists** [e.g., abciximab (ReoPro), eptifibatide (Integrilin), tirofiban (Aggrastat)], plicamycin). Risk of bleeding may be increased. Monitoring of coagulation tests may be indicated. ■ May inhibit effectiveness of **oral contraceptives;** breakthrough bleeding or pregnancy could result. ■ May decrease clearance and increase toxicity of **methotrexate.** ■ Clavulanic acid may cause a **false-positive Coombs' test.** ■ May cause **false urine protein reactions** with various tests; see Side Effects and/or literature.

SIDE EFFECTS

Diarrhea, nausea, phlebitis at injection site, and rash are most common. The most common laboratory abnormalities included elevations in eosinophils, AST, and ALT. Other reported side effects include anaphylaxis; anemia; arthralgia; CDAD; chest discomfort; chills; disturbances of taste and smell; elevated alkaline phosphatase, BUN, LDH, serum bilirubin, and serum creatinine; fever; flatulence; epigastric pain; headache; hemorrhagic cystitis; hypernatremia; hypokalemia; increased bleeding time; leukopenia; myalgia; neutropenia; phlebitis; prolonged clotting time or PT; pruritus; skin rash; stomatitis; thrombocytopenia; urticaria; vomiting. Higher than normal doses may cause neurologic adverse reactions, including convulsions, especially with impaired renal function.

Post-Marketing:

Stevens-Johnson syndrome, toxic epidermal necrolysis.

ANTIDOTE

Notify the physician immediately of any adverse symptoms. For severe symptoms, discontinue the drug; treat hypersensitivity reactions (epinephrine, antihistamines, corticosteroids), and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of ticarcillin/clavulanate. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Discontinue the drug if symptoms of bleeding manifestations appear, and treat as indicated. Hemodialysis may be indicated in overdose.

TIGECYCLINE FOR INJECTION BBW

(tye-ge-**SYE**-kleen)
Tygacil
Antibacterial (glycylcycline)
pH 7.8

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Precautions and Monitor.

Tigecycline:

100 mg as an initial dose. Follow with 50 mg every 12 hours. Recommended duration of treatment is 5 to 14 days for complicated skin and skin structure infections and complicated intra-abdominal infections and 7 to 14 days for community-acquired bacterial pneumonia. Duration of treatment is based on the severity and site of the infection and the patient's clinical and bacteriologic progress.

PEDIATRIC DOSE

See Maternal/Child.

DOSE ADJUSTMENTS

In patients with severe impaired liver function (Child-Pugh Class C), the initial dose remains the same, but subsequent doses should be reduced to 25 mg every 12 hours. ■ No dose adjustment is indicated for impaired renal function, for mild to moderate impaired liver function (Child-Pugh Class A and Child-Pugh Class B), or in patients undergoing hemodialysis. ■ No dose adjustment is indicated based on age, gender, or race. ■ There are no data to provide dosing recommendations in pediatric patients with hepatic impairment; see Maternal/Child.

DILUTION

Reconstitute each 50-mg vial with 5.3 mL of NS, D5W, or LR (yields 10 mg/mL). Use 2 vials for the 100-mg dose. Swirl gently until lyophilized powder is dissolved. Reconstituted solution should be yellow to orange in color. Immediately withdraw 5 mL from each of two vials for the 100-mg dose (vials have overfill) or from one vial for the 50-mg dose and add to a 100-mL IV bag of D5W, NS, or LR for infusion. Maximum concentration should be 1 mg/mL.

Filters:

No data available from manufacturer.

Storage:

Store unopened vials at CRT. Reconstituted solution may be stored at RT for up to 6 hours. Fully diluted solution in the IV bag may be stored at RT for up to 24 hours or for 6 hours in the vial and the remaining time in the IV bag, or the fully diluted solution in either D5W or NS may be refrigerated at 2° to 8° C (36° to 46° F) for up to 48 hours following immediate transfer of the reconstituted solution into the IV bag.

COMPATIBILITY

The following drugs ***should not*** be administered simultaneously through the same **Y-site** as tigecycline: amphotericin B (conventional), amphotericin B lipid complex, diazepam, esomeprazole, and omeprazole.

Y-site:

Compatible at the **Y-site** when used with NS or D5W: amikacin, aminophylline, dobutamine, dopamine, gentamicin, LR solution, lidocaine, metoclopramide, morphine, norepinephrine, piperacillin/tazobactam, potassium chloride, propofol, and tobramycin.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Flush IV line with D5W, NS, or LR before and after infusion of tigecycline if other drugs are administered through the same line; see Compatibility. Consider **compatibility** of other drugs when flushing the line.

A single dose as an infusion over 30 to 60 minutes.

ACTIONS

A broad-spectrum tetracycline class antibacterial agent that is bacteriostatic against specific aerobic gram-positive and gram-negative microorganisms and specific anaerobic microorganisms; see prescribing information. Inhibits protein translation in bacteria by binding to a specific ribosomal subunit and blocking entry of specific molecules into the A site of the ribosome, thereby inhibiting protein synthesis. Plasma protein binding is approximately 71% to 89%. Extensively distributed beyond the plasma volume and into tissues. For example, concentrations have been identified in the bone, colon, gallbladder, synovial fluid, and lung. Mean half-life is 42.4 hours. Not extensively metabolized. 59% of a dose is excreted in bile and feces, and 33% is excreted in urine.

INDICATIONS AND USES

Treatment of patients 18 years of age and older with infections caused by susceptible strains of designated microorganisms in complicated skin and skin structure infections, complicated intra-abdominal infections, and community-acquired bacterial pneumonia.

Limitations of use:

Tigecycline is not indicated for treatment of diabetic foot infections. ■ Tigecycline is not indicated for treatment of hospital-acquired or ventilator-associated pneumonia. In a comparator clinical trial, greater mortality and decreased efficacy were reported in the patients treated with tigecycline.

CONTRAINDICATIONS

Known hypersensitivity to tigecycline. Contains no excipients or preservatives.

PRECAUTIONS

An increase in all-cause mortality has been observed in a meta-analysis of Phase 3 and 4 clinical trials in tigecycline-treated patients versus comparator-treated patients. The cause of this increase has not been established. Tigecycline should be reserved for use in situations in which alternative treatments are not suitable. ■ A trial of patients with hospital-acquired (including ventilator-associated) pneumonia failed to demonstrate the efficacy of tigecycline; see Limitations of Use. ■ Sensitivity studies are indicated to determine susceptibility of the causative organism to tigecycline. Treatment may begin after culture and sensitivity studies are drawn. Re-evaluate after results are known. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, tigecycline should be used to treat only those infections proven or strongly suspected to be caused by bacteria. ■ Cross-resistance and/or antagonism between tigecycline and other antibiotics have not been observed. ■ Not affected by resistance mechanisms seen with other antibiotics (e.g., β-lactamases or ribosomal protection and efflux seen with other tetracyclines). However, some ESBL-producing isolates may confer resistance to tigecycline via other resistance mechanisms. ■ Structurally similar to the tetracycline class of antibiotics; may have similar side effects (e.g., antianabolic action [which has led to acidosis, azotemia, hyperphosphatemia, and increased BUN], photosensitivity, and pseudotumor cerebri). ■ Anaphylactic reactions have been reported. Should be avoided in patients with a history of hypersensitivity to tetracyclines; may have cross-sensitivity. ■ Acute pancreatitis, including fatalities, has been reported. ■ Monotherapy with tigecycline should be avoided in patients with complicated intra-abdominal infections secondary to clinically apparent intestinal perforation; sepsis/septic shock has occurred. ■ Abnormalities in total bilirubin, PT, and transaminases have been seen in patients treated with tigecycline. Isolated cases of significant hepatic dysfunction and hepatic failure have also been reported; see Monitor. ■ May cause permanent discoloration of the teeth during tooth development; see Maternal/Child. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with severe liver impairment. Reduced dose and monitoring for treatment response are indicated; see Dose Adjustments. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with tigecycline.

Monitor:

Monitor vital signs carefully. ■ Obtain baseline CBC with differential, and monitor as indicated. ■ Monitor liver function. If abnormal liver function tests develop, monitor closely for worsening hepatic function and evaluate for risk/benefit of continuing therapy. Hepatic dysfunction may occur after tigecycline is discontinued. ■ Monitor patients with severe hepatic impairment for treatment response; see Precautions and Dose Adjustments. ■ Monitor for S/S or laboratory abnormalities suggestive of acute pancreatitis. ■ Observe for signs of hypersensitivity reactions (e.g., chills, fever, hives, rash, shortness of breath). ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Avoid pregnancy; use effective contraceptive measures; see Drug/Lab Interactions. Should pregnancy occur, notify physician immediately and discuss potential hazards. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Promptly report S/S of hypersensitivity (e.g., chills, fever, hives, rash, shortness of breath) and/or S/S of liver dysfunction (e.g., jaundice or yellow sclera).

Maternal/Child:

Use during the second and third trimester of pregnancy may cause permanent discoloration of deciduous teeth and reversible inhibition of bone growth. Use of effective contraception required; see Drug/Lab Interactions. ■ Use during tooth development (the last half of pregnancy, infancy, and childhood to the age of 8 years) may cause permanent discoloration of the teeth and is not recommended. ■ Because of the risk of dental discoloration and inhibition of bone growth, avoid breast-feeding if taking tigecycline for longer than 3 weeks. Consider interrupting breast-feeding and pumping and discarding breast milk during treatment and for 9 days after the last dose to minimize drug exposure to breast-fed infant. ■ Safety and effectiveness for use in pediatric patients under 18 years of age have not been evaluated due to the observed increase in mortality associated with tigecycline in adult patients. Tigecycline should not be used in pediatric patients unless no alternative antibacterial drugs are available. Under these circumstances, the following doses are suggested: ***Pediatric patients 8 to 11 years of age*** should receive 1.2 mg/kg every 12 hours (not to exceed 50 mg every 12 hours). ***Pediatric patients 12 to 17 years of age*** should receive 50 mg every 12 hours.

Elderly:

Response similar to that seen in younger adults; however, the potential for greater sensitivity to side effects cannot be disregarded.

DRUG/LAB INTERACTIONS

May decrease clearance of warfarin. INR should be monitored if tigecycline is administered with warfarin. ■ May render **oral contraceptives** less effective, resulting in pregnancy or breakthrough bleeding. ■ Tigecycline is a substrate of P-glycoprotein (P-gp). Clinical relevance is not known. Coadministration of **P-gp inhibitors** (e.g., ketoconazole or cyclosporine) or **P-gp inducers** (e.g., rifampin) could affect the pharmacokinetics of tigecycline. ■ No reported interactions with lab tests.

SIDE EFFECTS

Nausea and vomiting are the most common side effects and are the primary reason for discontinuing therapy. Other commonly reported side effects include abdominal pain, diarrhea, headache, and increased ALT. Less commonly reported side effects include abnormal healing; abscess; anemia; asthenia; bilirubinemia; CDAD; dizziness; dyspepsia; hyponatremia; hypoproteinemia; increased alkaline phosphatase, amylase, AST, and BUN; infection; phlebitis; pneumonia; rash. Sepsis/septic shock and death occurred in a few patients with complicated infections.

Post-Marketing:

Acute pancreatitis, anaphylactic reactions, hepatic cholestasis, jaundice, severe skin reactions (including Stevens-Johnson syndrome), and symptomatic hypoglycemia in patients with and without diabetes.

Overdose:

Increased incidence of nausea and vomiting.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically; monitor closely. If minor side effects are progressive or if any major side effect occurs, discontinue the drug, treat hypersensitivity reactions, or resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of tigecycline. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Not removed by hemodialysis.

TIROFIBAN HYDROCHLORIDE

(ty-roh-**FYE**-ban hy-droh-**KLOR**-eyed)
Aggrastat
Antiplatelet agent
pH 5.5 to 6.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Tirofiban:

A ***loading infusion*** of 25 mcg/kg administered within 5 minutes followed by a ***maintenance infusion (CrCl over 60 mL/min)*** of 0.15 mcg/kg/min for up to 18 hours; see Dose Adjustments for dosing in patients with a CrCl equal to or less than 60 mL/min. See Rate of Administration for additional administration information. Has been used in combination with aspirin, clopidogrel (Plavix), and heparin or bivalirudin (Angiomax).

DOSE ADJUSTMENTS

After loading dose of 25 mcg/kg administered within 5 minutes, reduce maintenance dose to 0.075 mcg/kg/min for up to 18 hours in patients with a CrCl equal to or less than 60 mL/min. ■ No dose adjustment indicated based on age, race, gender, or hepatic impairment.

DILUTION

Multiple forms and strengths available. Available as an infusion solution in a 5 mg/100 mL vial or a 12.5 mg/250 mL bag (50 mcg/mL) or as a bolus vial containing 3.75 mg/15 mL (250 mcg/mL). Remove overwrap of the infusion bag. Plastic may be somewhat opaque due to sterilization process. Opacity should diminish. Squeeze inner container to check for leak. Discard if leakage noted; sterility is impaired.

Bolus dose:

Withdraw bolus dose of tirofiban from the 15-mL premixed bolus vial into a syringe. Alternatively, the bolus dose may be administered from the 100-mL premixed vial or from the 250-mL premixed bag. Do not dilute. Refer to the following equations to calculate bolus volume.

The recommended bolus volume using the 15-mL premixed bolus vial:

$$\underset{(\text{mL})}{\textbf{Bolus Volume}} = \frac{25\ \text{mcg/kg} \times \text{body weight (kg)}}{250\ \text{mcg/mL}}$$

The recommended bolus volume using the 100-mL premixed vial or 250-mL premixed bag:

$$\underset{(\text{mL})}{\textbf{Bolus Volume}} = \frac{25\ \text{mcg/kg} \times \text{body weight (kg)}}{50\ \text{mcg/mL}}$$

Storage:

Store unopened containers at 25° C (77° F). Variations from 15° to 30° C (59° to 86° F) are acceptable (CRT). Protect from light during storage. Do not freeze. Discard unused solution.

COMPATIBILITY

Do not add other drugs or remove solution directly from the bag with a syringe. Should not be administered in the same IV line as diazepam.

Compatibile at the **Y-site** with amiodarone, argatroban, atropine, bivalirudin, dobutamine, dopamine, epinephrine, famotidine, furosemide, heparin, lidocaine, midazolam, morphine, nitroglycerin IV, potassium chloride, propranolol.

RATE OF ADMINISTRATION

Loading infusion:

25 mcg/kg administered within 5 minutes via a syringe or IV pump. For patients weighing 167 kg or more, it is recommended that the bolus dose be administered via syringe from the 15-mL premixed bolus vial to ensure delivery time does not exceed 5 minutes.

Maintenance infusion:

CrCl greater than 60 mL/min:

0.15 mcg/kg/min for up to 18 hours.

CrCl equal to or less than 60 mL/min:

0.075 mcg/kg/min for up to 18 hours.

Administer the maintenance infusion from the 100-mL premixed vial or 250-mL premixed bag via an IV pump immediately following the bolus dose.

Infusion rate for CrCl greater than 60 mL/min using the 100-mL premixed vial or 250-mL premixed bag can be calculated as follows:

$$\begin{array}{c}\text{Infusion Rate for CrCl}\\ \text{>60 mL/min (mL/hr)}\end{array} = \frac{0.15\ \text{mcg/kg/min} \times \text{Body weight (kg)} \times 60\ \text{min/hr}}{50\ \text{mcg/mL}}$$

Example calculation of infusion rate for 60-kg patient with CrCl greater than 60 mL/min using the 100-mL premixed vial or 250-mL premixed bag:

$$\begin{array}{c}\text{Infusion Rate for CrCl}\\ \text{>60 mL/min (mL/hr)}\end{array} = \frac{0.15\ \text{mcg/kg/min} \times 60\ \text{kg} \times 60\ \text{min/hr}}{50\ \text{mcg/mL}} = 10.8\ \text{min/hr}$$

Infusion rate for CrCl 60 mL/min or less using the 100-mL premixed vial or 250-mL premixed bag can be calculated as follows:

$$\text{Infusion Rate for CrCl} \leq 60 \text{ mL/min (mL/hr)} = \frac{0.075 \text{ mcg/kg/min} \times \text{Body weight (kg)} \times 60 \text{ min/hr}}{50 \text{ mcg/mL}}$$

ACTIONS

A nonpeptide antagonist of the platelet glycoprotein GPIIb/IIIa receptor. It inhibits platelet aggregation by preventing the binding of fibrinogen to the receptor site on activated platelets. Inhibits platelet aggregation in a dose- and concentration-dependent manner. When given according to the recommended regimen, greater than 90% inhibition is attained within 10 minutes. Bleeding time is prolonged. Inhibition is reversible, with aggregation returning to baseline in more than 90% of patients within 4 to 8 hours following cessation of the infusion. Half-life is approximately 2 hours. Cleared from the plasma primarily by renal excretion, with about 65% of the unchanged drug appearing in the urine and about 25% appearing in feces. Metabolism is limited.

INDICATIONS AND USES

Indicated to reduce the rate of thrombotic cardiovascular events (combined end point of death, myocardial infarction, or refractory ischemia/repeat cardiac procedure) in patients with non–ST elevation acute coronary syndrome (NSTE-ACS).

CONTRAINDICATIONS

Severe hypersensitivity (e.g., anaphylaxis) to tirofiban. ■ A history of thrombocytopenia following prior exposure to tirofiban. ■ Active internal bleeding or a history of bleeding diathesis, major surgical procedure, or severe physical trauma within the previous month.

PRECAUTIONS

For intravenous use only. ■ Bleeding is the most common complication encountered during therapy. Most bleeding associated with tirofiban occurs at the arterial access site for cardiac catheterization; see Monitor. Fatal bleeding events have been reported. ■ Concomitant use of fibrinolytics, oral anticoagulants, and antiplatelet drugs increases the risk of bleeding; see Drug/Lab Interactions. ■ Profound thrombocytopenia has been reported. Previous exposure to GPIIb/IIIa receptor antagonists (e.g., eptifibatide, tirofiban) may increase the risk of developing thrombocytopenia. ■ Patients treated with tirofiban plus heparin were more likely to experience decreases in platelet counts than were patients on heparin alone. ■ Plasma clearance is decreased in patients with moderate to severe renal insufficiency; see Dose Adjustments. Safety and effectiveness not established for use in patients on hemodialysis. ■ Hypersensitivity reactions, including anaphylaxis, have been reported in post-marketing. They have occurred during initial infusion and during readministration.

Monitor:

Obtain platelet count, hemoglobin, and hematocrit before therapy, within 6 hours following the loading infusion, and at least daily thereafter. More frequent monitoring may be indicated. ■ If platelet count drops to below 90,000/mm^3, additional platelet counts should be performed to exclude pseudothrombocytopenia. If thrombocytopenia is confirmed, heparin and tirofiban should be discontinued and appropriate therapy initiated. ■ Obtain an aPTT before treatment and carefully monitor the anticoagulant effects of heparin by repeated determinations of aPTT; adjust heparin dose accordingly. ■ Monitor for S/S of hypersensitivity or infusion-related reactions (e.g., anaphylaxis, hypotension, pruritus, rash, urticaria, or wheezing). ■ Monitor the patient for signs of bleeding; take vital signs (avoiding automatic BP cuffs); observe any invaded sites at least every 15 minutes (e.g., sheaths, IV sites, cutdowns, punctures, epidural sites, Foleys, NGs); watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, muscle weakness. Perform neuro checks frequently. If during therapy bleeding cannot be controlled with pressure, tirofiban and heparin infusions should be discontinued. ■ Use care in handling patient; minimize use of urinary catheters, nasotracheal intubation, and nasogastric tubes. Avoid arterial puncture, venipuncture, epidural procedures, and IM injection. Use extreme precautionary methods and only compressible sites if these procedures are absolutely necessary (i.e., avoid subclavian or jugular veins). Apply pressure for 30 minutes to any invaded site and then apply pressure dressings. Saline or heparin locks suggested to facilitate blood draws.

Patient Education:

Compliance with all measures to minimize bleeding (e.g., strict bed rest, positioning) is imperative. ■ Avoid use of razors, toothbrushes, and other sharp items. ■ Use caution while moving to avoid excessive bumping. ■ Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face) and all episodes of bleeding, and apply local pressure if indicated. ■ Expect oozing from IV sites.

Maternal/Child:

Although published data cannot definitively establish the absence of risk, available case reports have not established an association between tirofiban use during pregnancy and major birth defects, miscarriage, or adverse maternal or fetal outcomes. Myocardial infarction is a medical emergency in pregnancy and can be fatal to the pregnant woman and fetus if left untreated. ■ No data on the presence of tirofiban in human milk, the effects of the drug on the breast-fed infant, or the effects of the drug on human milk production. Consider risk versus benefit. ■ Safety and efficacy for use in pediatric patients not established.

Elderly:

Effectiveness similar to that seen in younger patients. ■ Dose adjustment based solely on age is not necessary. Consider age-related renal impairment; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Use caution when given with drugs that affect hemostasis (e.g., **anticoagulants** [e.g., apixaban, heparin, rivaroxaban, warfarin], **NSAIDs**, **platelet aggregation inhibitors** [e.g., clopidogrel, dipyridamole], or **thrombolytic agents** [e.g., alteplase, reteplase, streptokinase]). Risk of bleeding is increased.

SIDE EFFECTS

Bleeding is the most frequent adverse event. Laboratory findings related to bleeding include decrease in hemoglobin, hematocrit, and platelet count and occult blood in urine and feces. Other side effects that occur at an incidence of greater than 1%, regardless of drug relationship, are bradycardia, dissection of the coronary artery, dizziness, edema, hypersensitivity reactions (e.g., hives, rash), leg pain, nausea, pelvic pain, sweating, thrombocytopenia, and vasovagal reflex.

Post-Marketing:

Hypersensitivity reactions (including anaphylaxis), severe thrombocytopenia. Fatal bleeding events have been reported.

ANTIDOTE

Keep physician informed of laboratory values and side effects. Discontinue the infusion of tirofiban and heparin if any serious bleeding not controllable with pressure occurs. If platelet count drops to below 90,000 mm^3, obtain additional platelet counts to exclude pseudothrombocytopenia. If thrombocytopenia is confirmed, discontinue tirofiban and heparin. Platelet transfusion may be required. If a hypersensitivity reaction should occur, discontinue the infusion and treat as indicated by severity (e.g., epinephrine, dopamine, theophylline, antihistamines [e.g., diphenhydramine], and/or corticosteroids as necessary).

No specific antidote is available. Overdosage should be treated by assessment of the patient's clinical condition and cessation or adjustment of the drug infusion as appropriate. Hemodialysis may be useful in an overdose situation.

TISAGENLECLEUCEL BBW

(**TIS**-a-**JEN**-lek-**LOO**-sel)
Kymriah
Chimeric antigen receptor T-cell (CAR-T)
Immunotherapy
Antineoplastic

USUAL DOSE

Pretreatment:

Screen patients for HBV, HCV, and HIV before leukapheresis procedure. See Precautions and Drug/Lab Interactions. Confirm the availability of tisagenlecleucel before starting the lymphodepleting chemotherapy regimen. See Maternal/Child.

Treatment course consists of fludarabine and cyclophosphamide lymphodepleting chemotherapy followed by infusion of tisagenlecleucel.

Lymphodepleting chemotherapy:

Fludarabine (30 mg/M² IV daily for 4 days) and ***cyclophosphamide*** (500 mg/M² IV daily for 2 days starting with the first dose of fludarabine). See fludarabine and cyclophosphamide monographs.

Premedication:

Premedicate with acetaminophen and diphenhydramine or another H_1-antihistamine 30 to 60 minutes before tisagenlecleucel infusion. Ensure tocilizumab and emergency equipment are available.

Tisagenlecleucel:

Provided in a single-dose unit containing chimeric antigen receptor (CAR)–positive viable T-cells[a] based on patient weight reported at the time of leukapheresis. Patient's identity must match the patient identifiers on the tisagenlecleucel infusion bag. Patient identifier number may be preceded by the letters DIN or Aph ID. Do not infuse if the information on the patient-specific label does not match the intended patient.

Target dose of tisagenlecleucel:

Infuse 2 to 14 days after completion of the lymphodepleting chemotherapy. Coordinate the timing of thaw of tisagenlecleucel and infusion; see Dilution.

Patients weighing 50 kg or less:

0.2 to 5 × 10^6 CAR-positive viable T-cells per kg body weight.

Patients weighing more than 50 kg:

0.1 to 2.5 × 10^8 CAR-positive viable T-cells per kg body weight.

PEDIATRIC DOSE

See Usual Dose.

DOSE ADJUSTMENTS

Delay tisagenlecleucel infusion for unresolved serious adverse reactions from preceding chemotherapies (including pulmonary reactions, cardiac reactions, or hypotension), active uncontrolled infection, active graft-versus-host disease (GVHD), or worsening of leukemia burden after lymphodepleting chemotherapy.

DILUTION

Special handling required; see Precautions. Confirm the infusion time in advance, and adjust the start time for thaw so that tisagenlecleucel is available for infusion when the recipient is ready. Provided in a single-dose unit containing CAR-positive viable T-cells based on patient weight reported at the time of leukapheresis (volume in the infusion bag ranges from 10 to 50 mL). Confirm patient identity. Inspect the infusion bag for breaks or cracks before thawing; if compromised, do not infuse. Before thawing, place the infusion bag inside a second sterile bag in case of a leak and to protect ports from contamination. Thaw tisagenlecleucel at 37° C using either a water bath or dry thaw method until there is no visible ice. Remove bag from thawing device immediately; do not store product bag at 37° C. Once thawed and at room temperature, tisagenlecleucel should be infused within 30 minutes. Do not wash, spin down, and/or resuspend in new media before infusion. Inspect thawed infusion bag for visible cell clumps. If visible cell clumps remain, gently mix the contents of the bag. Small clumps should disperse with gentle manual mixing. Do not infuse if clumps are not dispersed or if the infusion bag is damaged or leaking or otherwise appears to be compromised. The thawed product is colorless to slightly yellow.

Filters:

DO NOT use a leukodepleting filter.

Storage:

Each infusion bag is individually packed for a specific patient and stored in the vapor phase of liquid nitrogen and supplied in a liquid nitrogen dry shipper. Store frozen in the vapor phase of liquid nitrogen (−120° C or below) in a temperature-monitored system. Once thawed, tisagenlecleucel may be stored at RT (20° to 25° C) for up to 30 minutes.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

For IV use only. ***DO NOT use*** a leukodepleting filter. Prime tubing with NS. Infuse the entire contents of the product bag at a rate of 10 to 20 mL/min. Adjust as appropriate for smaller pediatric patients and smaller volumes. After completion, rinse the infusion bag with 10 to 30 mL NS and administer at the same infusion rate to ensure all product is delivered.

ACTIONS

A CD19-directed, genetically modified, autologous T-cell immunotherapy. To prepare tisagenlecleucel, a patient’s own T-cells are harvested through a standard leukapheresis procedure and genetically modified. The patient’s T-cells are reprogrammed with a transgene encoding a chimeric antigen receptor (CAR) to identify and eliminate CD19-expressing malignant and normal cells. The CAR is made up of a murine single-chain antibody fragment that recognizes CD19 and is fused to intracellular signaling domains from 4-1BB (CD137) and CD3zeta. When tisagenlecleucel is then administered to the specific patient, it binds to his or her CD19-expressing cancer cells, and the CAR transmits a signal to promote T-cell expansion, activation, target cell elimination, and persistence of the tisagenlecleucel cells. Following the infusion of tisagenlecleucel in pediatric and young adult patients with relapsed/refractory B-cell acute lymphoblastic leukemia (AKK), it exhibited an initial rapid expansion followed by a biexponential decline. Tisagenlecleucel was present in the blood and bone marrow and was measurable beyond 2 years.

INDICATIONS AND USES

Treatment of patients up to 25 years of age with B-cell precursor acute lymphoblastic leukemia (ALL) that is refractory or in second or later relapse.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For autologous use only. ■ ***For IV use only.*** ■ Contains human blood cells capable of transmitting infectious disease; follow local biosafety guidelines for handling and disposal. ■ Administer under the direction of a physician knowledgeable in its use in a certified health care facility with the ability to monitor the patient and respond to any medical emergency. Tocilizumab (Actemra) (at least 2 doses) and emergency drugs and equipment must be available before the infusion and during the recovery period. ■ Cytokine release syndrome (CRS), including fatal or life-threatening reactions, has occurred in patients receiving tisagenlecleucel Do not administer to patients with active infection or inflammatory disorders. Other risk factors for severe CRS are high preinfusion tumor burden (greater than 50% blasts in bone marrow) and uncontrolled or accelerating tumor burden following lymphodepleting chemotherapy. Treat severe or life-threatening CRS with tocilizumab or tocilizumab and corticosteroids; see Monitor. ■ Severe or life-threatening neurologic toxicities can occur in patients receiving tisagenlecleucel. ■ Available only through a restricted program under a Risk Evaluation and Mitigation Strategy (REMS) called the KYMRIAH REMS; see prescribing information. ■ Serious hypersensitivity reactions, including anaphylaxis, may occur. May be due to dimethyl sulfoxide (DMSO) or dextran 40 in tisagenlecleucel. ■ Serious infections, including life-threatening or fatal infections, have occurred. Bacterial and viral infections, fungal infections, and infections caused by unspecified pathogens have been reported. ■ Hepatitis B virus (HBV) reactivation (in some cases resulting in fulminant hepatitis, hepatic failure, and death) can occur. ■ Prolonged cytopenias, including anemia, neutropenia, and thrombocytopenia, have been reported. Prolonged neutropenia has been associated with increased risk of infection. ■ B-cell aplasia and hypogammaglobulinemia can occur. ■ Secondary malignancies may develop; see prescribing information to obtain instructions on patient samples to collect for testing. ■ Has the potential to induce immunogenicity (antiproduct antibodies).

Monitor:

Patients are to remain within 2 hours of the certified health care facility for at least 4 weeks after infusion. ■ Screen patients for HBV, HCV, and HIV before the leukapheresis procedure. ■ Monitor CBC and platelets after the tisagenlecleucel infusion. ■ Monitor for S/S of infection before and after infusion and treat appropriately. Prophylactic antibiotics may be indicated. ■ Manage febrile neutropenia with broad-spectrum antibiotics, fluids, and supportive care as medically indicated. ■ Monitor for S/S of CRS (e.g., chills, dyspnea, fever, hypotension, hypoxia, tachycardia). Median time to onset was 3 days (range 1 to 22 days), and median duration was 8 days. Serious events that may be associated with CRS include cardiac, hepatic, and renal dysfunction and coagulopathy. Treat severe or life-threatening CRS with tocilizumab or tocilizumab and corticosteroids. Monitor for S/S of CRS for at least 4 weeks after treatment with tisagenlecleucel. CRS is identified based on clinical presentation. Evaluate for and treat other causes of fever, hypotension, or hypoxia. If CRS is suspected, immediately evaluate the patient for hospitalization and institute treatment with supportive care, tocilizumab, and/or corticosteroids as indicated in the following chart.

Treatment of Cytokine Release Syndrome (CRS)	
CRS Severity	**Management**
Prodromal Syndrome: • Anorexia • Fatigue • Low-grade fever	Observe in person; exclude infection; administer antibiotics per local guidelines if neutropenic; provide symptomatic support.
Overt CRS (one or more of the following): • High fever • Hypoxia • Mild hypotension	Administer antipyretics, oxygen, IV fluids, and/or low-dose vasopressors as needed.
Severe or Life-Threatening CRS (one or more of the following): • Hemodynamic instability despite IV fluids and vasopressor support • Worsening respiratory distress, including pulmonary infiltrates; increasing oxygen requirements, including high-flow oxygen and/or need for mechanical ventilation • Rapid clinical deterioration	Administer high-dose or multiple vasopressors, oxygen, mechanical ventilation, and/or other supportive care as needed. Administer tocilizumab: • *Patients weighing less than 30 kg:* 12 mg/kg IV over 1 hour • *Patients weighing 30 kg or more:* 8 mg/kg IV over 1 hour (maximum dose 800 mg)
Resistant CRS: No clinical improvement in 12 to 18 hours (or worsening at any time) despite prior management	Administer multiple vasopressors, oxygen, mechanical ventilation, and/or other supportive care as needed. Administer methylprednisolone 2 mg/kg as an initial dose, then 2 mg/kg per day until vasopressors and high-flow oxygen are no longer needed, then taper quickly. If no response to steroids within 24 hours, repeat the administration of tocilizumab: • *Patients weighing less than 30 kg:* 12 mg/kg IV over 1 hour • *Patients weighing 30 kg or more:* 8 mg/kg IV over 1 hour (maximum dose 800 mg) If no response to the second dose of tocilizumab within 24 hours, consider a third dose of tocilizumab, or pursue alternative measures for treatment of CRS.

■ Monitor immunoglobulin levels after the tisagenlecleucel infusion. Manage using infection precautions, antibiotic prophylaxis, and immunoglobulin replacement. ■ Monitor life-long for secondary malignancies. ■ Monitor for S/S of neurologic toxicities (e.g., anxiety, delirium, encephalopathy, headache, tremor). Other neurologic toxicities included agitation, aphasia, confusion, disturbances in consciousness, disorientation, mutism, and seizures. Most occur within the first 8 weeks after the initial infusion and resolved within 12 days. Onset of neurologic toxicity can be concurrent with CRS after resolution of CRS or in the absence of CRS. Rule out other causes of neurologic symptoms. Provide supportive care as needed. ■ Monitor for S/S of a hypersensitivity reaction (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing).

Patient Education:

Read the FDA-approved patient medication guide. ■ Patients should discuss all medical problems and all medications, including prescription and over-the-counter medications, with their health care provider. ■ Patients must remain within 2 hours of the certified health care facility for at least 4 weeks after infusion. ■ Periodic monitoring of blood counts is required. ■ Seek immediate medical attention for S/S of CRS (e.g., chills, fatigue, fever, nausea, tachycardia, hypotension, hypoxia). ■ Promptly report S/S of infection (e.g., fever, chills). Screening for HBV, HCV, and HIV indicated before treatment. ■ Immunoglobulin replacement may be indicated for an indefinite time after treatment. ■ Promptly report S/S of neurologic toxicities (e.g., changes in level of consciousness, confusion, delirium, loss of balance, speech disorders, seizures, tremors). Refrain from driving and engaging in hazardous occupations or activities for at least 8 weeks after the infusion. ■ Verify pregnancy status of females with reproductive potential before starting treatment with tisagenlecleucel. ■ Effective contraception recommended for patients receiving lymphodepleting chemotherapy. See cyclophosphamide and fludarabine monographs for additional information. ■ Inform health care provider treating you if you develop secondary malignancies ■ Inform any health care provider treating you that you have received tisagenlecleucel.

Maternal/Child:

Not recommended for women who are pregnant, and pregnancy after the infusion should be discussed with the treating physician. Based on the mechanism of action, the transduced cells may cause fetal toxicity, including B-cell lymphocytopenia, if they cross the placenta. ■ Safety for use during breast-feeding not established; effects unknown. ■ Pregnant women who have received tisagenlecleucel may have hypogammaglobulinemia. Assess immunoglobulin levels in newborns of mothers treated with tisagenlecleucel. ■ Safety and effectiveness for use in pediatric patients have not been established.

Elderly:

Safety and effectiveness for use in elderly patients not established. Clinical studies did not include patients 65 years of age or older.

DRUG/LAB INTERACTIONS

Safety of immunization with live virus vaccines during or after treatment with tisagenlecleucel has not been studied. Vaccination with **live virus vaccines** is not recommended for at least 2 weeks before the start of lymphodepleting chemotherapy, during treatment, and until immune recovery after treatment. ■ Some commercial HIV nucleic acid test (NAT) tests may yield false-positive results in patients who have received tisagenlecleucel. ■ Additional specific information on Drug/Lab Interactions not available.

SIDE EFFECTS

Acute kidney injury, bleeding episodes, cytokine release syndrome, decreased appetite, delirium, diarrhea, encephalopathy, fatigue, fever, headache, hypogammaglobulinemia, hypotension, infections (pathogens unspecified), hypoxia, nausea, tachycardia, viral infectious disorders, and vomiting are the most common adverse reactions. Other adverse events that occurred in at least 10% of patients include abdominal pain, anxiety, arthralgia, chills, constipation, cough, edema, elevated INR, fluid overload, hypertension, hypokalemia, hypophosphatemia, hypoxia, increased liver function tests, myalgia, nasal congestion, pain, pleural effusions, pulmonary edema, and tachypnea. All patients experienced anemia, neutropenia, and thrombocytopenia. Potentially serious reactions include cytokine release syndrome, hypersensitivity reactions, hypogammaglobulinemia, infections, neurologic toxicities, and prolonged cytopenias.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Treat side effects aggressively. Treat severe or life-threatening CRS with tocilizumab or tocilizumab and corticosteroids. See chart in Monitor for treatment of CRS at varying degrees of severity. Patients with CRS or neurologic toxicities may require monitoring with continuous cardiac telemetry and pulse oximetry. Consider intensive care supportive therapy for severe or life-threatening CRS or neurologic toxicities. Consider nonsedating antiseizure medicines (e.g., levetiracetam [Keppra]) for seizure prophylaxis in neurologic toxicities. Treating prolonged neutropenia with myeloid growth factors, particularly GM-CSF, is not recommended during the first 3 weeks after tisagenlecleucel infusion or **until CRS has resolved**. Treat hypersensitivity reactions as necessary (e.g., antihistamines, epinephrine, corticosteroids). Resuscitate if indicated.

TOBRAMYCIN SULFATE BBW

(toe-brah-**MY**-sin **SUL**-fayt)
Antibacterial (aminoglycoside)
pH 3 to 6.5

USUAL DOSE

Pretreatment:

See Maternal/Child.

Tobramycin:

3 mg/kg of body weight/24 hr equally divided into 3 doses and given every 8 hours (1 mg/kg every 8 hours). Up to 5 mg/kg equally divided into 3 or 4 doses may be given in life-threatening infections (1.25 mg/kg every 6 hours or 1.67 mg/kg every 8 hours). Reduce to usual dose as soon as feasible. For obese patients, the dosing weight used to calculate the mg/kg dose is achieved by adding the ideal or lean body weight (IBW) to 40% of the excess over IBW.

$$\text{Dosing weight} = \text{IBW} + 0.4\,(\text{Total body weight} - \text{IBW})$$

Do not exceed 5 mg/kg/day unless serum levels are monitored.

Studies suggest that in certain populations a single daily dose of 5 to 7 mg/kg (instead of divided into 2 to 3 doses) may provide higher peak levels and enhance drug effectiveness while actually reducing or having no adverse effects on risk of toxicity. Various procedures for monitoring blood levels are in use. Some health facilities are monitoring with trough levels; others may draw levels at predetermined times and plot the concentration on nomograms. Depending on the protocol in place, doses or intervals may be adjusted. See Dose Adjustments and Precautions.

Patients with cystic fibrosis:

One source suggests 7.5 to 10.5 mg/kg/24 hr equally divided into 3 doses and given every 8 hours for 7 to 21 days (2.5 to 3.5 mg/kg every 8 hours).

PEDIATRIC DOSE

In pediatric and neonatal patients, monitor serum levels. Wide interpatient variability; see Monitor and Maternal/Child.

Over 1 week of age:

6 to 7.5 mg/kg of body weight/24 hr in 3 or 4 equally divided doses (1.5 to 1.89 mg/kg every 6 hours or 2 to 2.5 mg/kg every 8 hours). Another source suggests the same as adult dose.

A single daily dose is also being used in pediatric patients. See comments under Usual Dose.

Severe cystic fibrosis:

10 mg/kg/day in equally divided doses every 6 hours (2.5 mg/kg every 6 hours).

NEONATAL DOSE

1 week of age or less:

Up to 4 mg/kg of body weight/24 hr in two equal doses every 12 hours (up to 2 mg/kg every 12 hours). Lower doses may be safer because of immature kidney function. 2.5 mg/kg every 18 hours or 3 mg/kg every 24 hours may provide acceptable peak and trough levels in neonates weighing less than 2,000 Gm. See Maternal/Child.

DOSE ADJUSTMENTS

Reduce daily dose commensurate with amount of renal impairment and/or increase intervals between injections. Measurement of serum concentrations following a loading dose of 1 mg/kg is suggested. Adjust subsequent doses accordingly. ■ Once-daily dosing is not usually used in patients with ascites, burns covering more than 20% of the total body surface area, CrCl less than 40 mL/min (including patients requiring dialysis), CrCl greater than 120 mL/min, cystic fibrosis, endocarditis, mycobacterium infections, or in infants or during pregnancy. ■ Reduced doses or extended intervals may be required in the elderly. ■ See Drug/Lab Interactions.

DILUTION

Prepared solutions equal 10 or 40 mg/mL. Further dilute each single dose in 50 to 100 mL of NS or D5W and administer through an additive tubing. Also available in ADD-Vantage vials for use with ADD-Vantage infusion containers. Reduce volume of diluent proportionately for pediatric patients.

Storage:

Store at CRT.

COMPATIBILITY

Manufacturer states, “Do not physically premix with other drugs; administer separately.” Inactivated in solution with beta-lactam antibiotics (e.g., cephalosporins, penicillins) and vancomycin; do not mix in the same solution. Appropriate spacing required because of physical **incompatibilities.** See Drug/Lab Interactions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each single dose, properly diluted, over a minimum of 20 and a maximum of 60 minutes.

ACTIONS

An aminoglycoside antibiotic with potential neuromuscular blocking action. Inhibits protein synthesis in bacterial cells. Bactericidal against specific gram-negative bacilli, including *Escherichia coli, Klebsiella, Proteus,* and *Pseudomonas*. Well distributed through all body fluids. Usual half-life is 2 to 2.5 hours. Half-life is prolonged in infants, postpartum females, fever, liver disease and ascites, spinal cord injury, cystic fibrosis, and the elderly; shorter in severe burns. Crosses the placental barrier. Excreted in the kidneys.

INDICATIONS AND USES

Short-term treatment of serious infections caused by susceptible organisms. Indicated infections include septicemia; lower respiratory tract infections; CNS infections (meningitis); intra-abdominal infections (including peritonitis); skin, bone, and skin structure infections; and complicated and recurrent urinary tract infections. ■

Primarily used when penicillin and other less toxic antibiotics are ineffective or contraindicated. ■ Concurrent therapy with a penicillin or cephalosporin sometimes indicated.

CONTRAINDICATIONS

Known tobramycin or aminoglycoside sensitivity. Sulfite sensitivity may be a contraindication.

PRECAUTIONS

Use extreme caution if therapy is required over 7 to 10 days. ■ Sensitivity studies necessary to determine susceptibility of causative organism to tobramycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, tobramycin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ Use caution in infants, children, the elderly, and patients with congestive heart failure, extensive burns, or muscular disorders. ■ May contain sulfites; use caution in patients with asthma. ■ Potentially nephrotoxic, ototoxic, and neurotoxic. Risk for neurotoxicity (e.g., auditory and vestibular ototoxicity) increased in patients with pre-existing renal damage or in normal renal function with prolonged use. Partial or total irreversible deafness may continue to develop after tobramycin is discontinued. ■ Aminoglycosides are nephrotoxic; risk for nephrotoxicity increased in patients with impaired renal function and in patients who receive high doses or prolonged therapy. ■ Single daily dosing has been used effectively in abdominal, pelvic inflammatory, and GU infections in patients with normal renal function. Not recommended in bacteremia caused by *Pseudomonas aeruginosa,* endocarditis, meningitis, during pregnancy, or in patients less than 6 weeks postpartum. Limited data available for use in all other situations (e.g., burns, pediatric patients or the elderly, cystic fibrosis, renal impairment). ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with tobramycin.

Monitor:

Watch for decrease in urine output, rising BUN and SCr, and declining CrCl levels. Dose may need to be reduced. ■ Closely monitor renal and eighth cranial nerve function, especially in patients with known or suspected reduced renal function at onset of therapy and in patients who develop signs of renal dysfunction during therapy. Monitor urine for decreased specific gravity, increased protein, and the presence of cells or casts. Serial audiograms are recommended, particularly in high-risk patients. ■ Closely monitor patients with impaired renal function for nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity, convulsions, muscle twitching, numbness, tingling); nephrotoxicity may be reversible. ■ Routine evaluation of hearing is recommended. ■ Narrow range between toxic and therapeutic levels. Periodically monitor peak and trough concentrations to avoid peak serum concentrations above 12 mcg/mL and trough concentrations above 2 mcg/mL (indicates accumulation). With traditional dosing, therapeutic levels are between 4 and 8 mcg/mL depending on site and severity of infection. Accumulation, excessive peak concentrations, advanced age, cumulative doses, and dehydration may contribute to ototoxicity and nephrotoxicity. ■ Maintain good hydration. ■ Monitor serum calcium, magnesium, potassium, and sodium; levels may decline. ■ In extended treatment, monitoring of serum levels, electrolytes, renal, auditory, and vestibular functions daily is recommended. ■ See Drug/Lab Interactions.

Patient Education:

Report promptly dizziness, hearing loss, weakness, or any changes in balance. ■ Effective birth control required. Avoid pregnancy. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category D: avoid pregnancy; use during pregnancy and breast-feeding only when absolutely necessary. Potential hazard to fetus. ■ Peak concentrations are generally lower in infants and young children. ■ Use extreme caution in premature infants and neonates; immature kidney function will result in prolonged half-life. ■ See Precautions.

Elderly:

Consider less toxic alternatives. ■ Monitor renal function and drug levels carefully. Measurement of CrCl more useful than BUN or SCr to assess renal function. ■ Half-life prolonged; longer intervals between doses may be more important than reduced doses. ■ See Precautions, Dose Adjustments, and Side Effects.

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **beta-lactam antibiotics** (e.g., cephalosporins, penicillins) **and vancomycin.** Synergism may be inconsistent; see Compatibility. ■ Concurrent and/or sequential use topically or systemically with any other neurotoxic, ototoxic, or nephrotoxic agents should be avoided. May have dangerous additive effects with **anesthetics and other neuromuscular blocking antibiotics** (e.g., other aminoglycosides). ■ **Neuromuscular blocking muscle relaxants** (e.g., atracurium, succinylcholine) are potentiated by aminoglycosides. ***Apnea can occur.*** ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, and tetracycline); bactericidal action may be affected. ■ **Magnesium sulfate** may reduce the antibiotic activity of tobramycin. ■ Aminoglycosides are potentiated by **anticholinesterases** (e.g., edrophonium), **antineoplastics** (e.g., nitrogen mustard, cisplatin). ■ See Side Effects.

SIDE EFFECTS

Occur more frequently with impaired renal function, higher doses, prolonged administration, dehydration, in the elderly, and in patients receiving other ototoxic or nephrotoxic drugs.

Dizziness; fever; headache; increased AST, ALT, and serum bilirubin; itching; lethargy; rash; roaring in the ears; seizures; urticaria; vomiting.

Major:

Apnea; blood dyscrasias; CDAD; cylindruria; elevated BUN, nonprotein nitrogen (NPN), and creatinine; hearing loss; leukocytosis; neuromuscular blockade; oliguria; proteinuria; seizures (large doses); tinnitus; vertigo.

ANTIDOTE

Notify the physician of all side effects. If minor side effects persist or any major symptom appears, discontinue the drug and notify the physician. Evidence of impaired renal, vestibular, or auditory function requires discontinuation of tobramycin or a dose adjustment. Treatment is symptomatic or a reduction in dose may be required. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. In overdose hemodialysis may be indicated. Monitor fluid balance, CrCl, and plasma levels carefully. Complexation with ticarcillin may be as effective as hemodialysis. Consider exchange transfusion in the newborn. Calcium salts or neostigmine may reverse neuromuscular blockade. Resuscitate as necessary.

TOCILIZUMAB BBW

(**TOE**-si-**LIZ**-oo-mab)
Actemra
Antirheumatic; disease-modifying anti-rheumatic drug (DMARD)
Monoclonal antibody
pH 6.5

USUAL DOSE

Pretreatment:

Pretesting and baseline studies required and prescreening may be indicated; see Monitor.

Before initial use, the absolute neutrophil count (ANC) should be equal to or greater than $2,000/mm^3$, platelet count should be equal to or greater than $100,000/mm^3$, and ALT and AST should be no more than 1.5 times the ULN.

Rheumatoid arthritis (RA): Initial adult dose in rheumatoid arthritis:

4 mg/kg as an IV infusion once every 4 weeks. Increase dose to 8 mg/kg every 4 weeks based on clinical response. May be used as monotherapy or in combination with methotrexate or other nonbiologic DMARDs as an IV infusion or SC injection. Doses above 800 mg per infusion are not recommended. See prescribing information for SC dosing, intervals, and dose adjustments. When transitioning from IV to SC administration, administer the first SC dose instead of the next scheduled IV dose.

Polyarticular juvenile idiopathic arthritis (PJIA):

Weight less than 30 kg:

10 mg/kg.

Weight at or above 30 kg:

8 mg/kg. Administer as an IV infusion once every 4 weeks. May be used alone or in combination with methotrexate. Do not adjust dose based on a single-visit body weight; weight may fluctuate. See prescribing information for SC dosing and intervals. When transitioning from IV to SC administration, administer the first SC dose instead of the next scheduled IV dose

Systemic juvenile idiopathic arthritis (SJIA):

Weight less than 30 kg:

12 mg/kg.

Weight equal to or more than 30 kg:

8 mg/kg. Administer as an IV infusion once every 2 weeks. May be used as an IV infusion or as a SC injection alone or in combination with methotrexate. Do not adjust dose based on a single-visit body weight; weight may fluctuate. See prescribing information for SC dosing and intervals. When transitioning from IV to SC administration, administer the first SC dose instead of the next scheduled IV dose

Cytokine release syndrome (CRS):

Weight less than 30 kg:

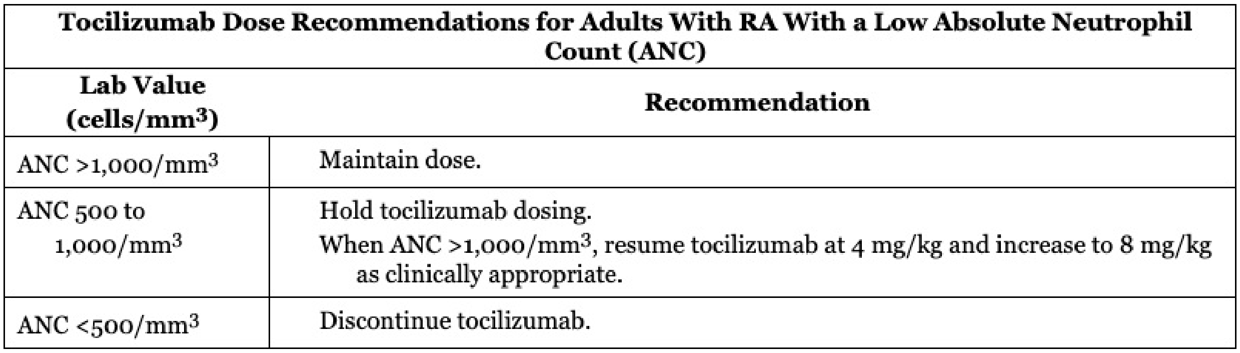
12 mg/kg.

Weight 30 kg or more:

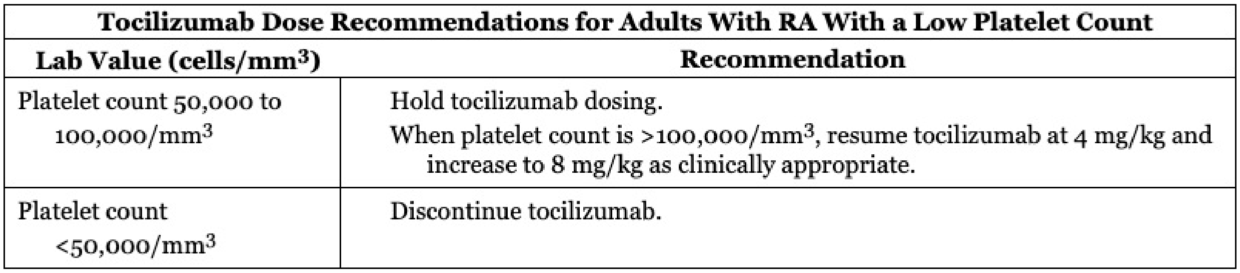
8 mg/kg. Administer as an IV infusion over 60 minutes. May be used alone or in combination with corticosteroids. If no clinical improvements in the S/S of CRS occur after the first dose, up to 3 additional doses may be administered. The interval between consecutive doses should be at least 8 hours. Doses exceeding 800 mg per infusion are not recommended. For IV administration only; SC administration is not approved for CRS.

DOSE ADJUSTMENTS

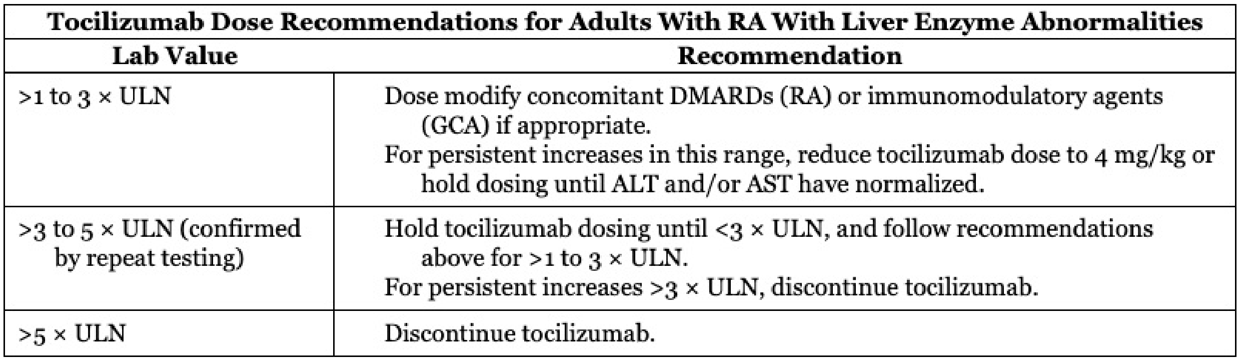
When given IV on a mg/kg basis, patients with a body weight 100 kg or greater are predicted to have a mean steady-state exposure higher than mean values for the patient population. Therefore doses exceeding 800 mg are not recommended; see Usual Dose. No specific dose adjustments required based on age, gender, race, or mild or moderate renal impairment. ■ Hold therapy in patients with severe infections until infection is controlled. ■ Dose reduction has not been studied in PJIA or SJIA. Dose interruptions are recommended for liver enzyme abnormalities, low neutrophil counts, and low platelet counts in patients with PJIA or SJIA at levels similar to those outlined in the following charts for patients with rheumatoid arthritis (RA). May require interruption or discontinuation of tocilizumab and/or dose modification, interruption, or discontinuation of other concomitant medications (e.g., methotrexate) until evaluation of the clinical situation. The decision to discontinue tocilizumab for a lab abnormality should be based on medical assessment of the individual. ■ The effects of severe renal impairment or hepatic impairment have not been studied. ■ The following charts outline dose adjustments for adults with RA based on ANC, platelets, and liver function tests.



Tocilizumab Dose Recommendations for Adults With RA With a Low Absolute Neutrophil Count (ANC)	
Lab Value (cells/mm^3)	**Recommendation**
ANC >1,000/mm^3	Maintain dose.
ANC 500 to 1,000/mm^3	Hold tocilizumab dosing. When ANC >1,000/mm^3, resume tocilizumab at 4 mg/kg and increase to 8 mg/kg as clinically appropriate.
ANC <500/mm^3	Discontinue tocilizumab.



Tocilizumab Dose Recommendations for Adults With RA With a Low Platelet Count	
Lab Value (cells/mm^3)	**Recommendation**
Platelet count 50,000 to 100,000/mm^3	Hold tocilizumab dosing. When platelet count is >100,000/mm^3, resume tocilizumab at 4 mg/kg and increase to 8 mg/kg as clinically appropriate.
Platelet count <50,000/mm^3	Discontinue tocilizumab.



Tocilizumab Dose Recommendations for Adults With RA With Liver Enzyme Abnormalities	
Lab Value	**Recommendation**
>1 to 3 × ULN	Dose modify concomitant DMARDs (RA) or immunomodulatory agents (GCA) if appropriate. For persistent increases in this range, reduce tocilizumab dose to 4 mg/kg or hold dosing until ALT and/or AST have normalized.
>3 to 5 × ULN (confirmed by repeat testing)	Hold tocilizumab dosing until <3 × ULN, and follow recommendations above for >1 to 3 × ULN. For persistent increases >3 × ULN, discontinue tocilizumab.
>5 × ULN	Discontinue tocilizumab.

ULN, Upper limit of normal.

DILUTION

Available as a solution for single use (20 mg/mL). For patients weighing 30 kg or more, the solution must be further diluted to 100 mL in NS or 0.45 NS. For patients weighing less than 30 kg, dilute to 50 mL in NS or 0.45 NS. From a 100-mL (or 50-mL) infusion bag or bottle, withdraw a volume of NS or 0.45 NS equal to the volume of solution required for the calculated dose. Slowly add tocilizumab and avoid foaming by gently inverting the bag or bottle. Bring fully diluted solution to RT before administration.

For Intravenous Use: Volume of Tocilizumab Injection per kg of Body Weight		
Dose	**Indication**	**Volume of Tocilizumab Injection per kg of Body Weight**
4 mg/kg	Adult RA	0.2 mL/kg
8 mg/kg	Adult RA PJIA, SJIA, and CRS (≥30 kg of body weight)	0.4 mL/kg
10 mg/kg	PJIA (<30 kg of body weight)	0.5 mL/kg
12 mg/kg	SJIA and CRS (<30 kg of body weight)	0.6 mL/kg

Filters:

Specific information not available.

Storage:

Refrigerate unopened vials in original carton at 2° to 8° C (36° to 46° F). Do not use beyond expiration date. Protect from light. Do not freeze. Fully diluted solutions for infusion using NS may be refrigerated at 2° to 8° C (36° to 46° F) or stored at RT for up to 24 hours. Fully diluted solutions for infusion using 0.45 NS may be refrigerated at 2° to 8° C (36° to 46° F) for up to 24 hours or stored at RT for up to 4 hours. Protect from light. Discard unused solution.

COMPATIBILITY

Manufacturer states, “Fully diluted solutions are **compatible** with polypropylene, polyethylene, and polyvinyl chloride infusion bags and with polypropylene, polyethylene, and glass infusion bottles. Tocilizumab should not be infused concomitantly in the same intravenous line with other drugs.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 60 minutes. Do not administer as an IV push or bolus.

ACTIONS

A recombinant humanized antihuman interleukin 6 (IL-6) receptor monoclonal antibody. Binds specifically to both soluble and membrane-bound IL-6 receptors. Inhibits IL-6–mediated signaling through these receptors. IL-6 is a pro-inflammatory cytokine produced by a variety of cell types. IL-6 is also produced by synovial and endothelial cells leading to local production of IL-6 in joints affected by inflammatory processes such as rheumatoid arthritis. IL-6 has been shown to be involved in diverse physiologic processes such as T-cell activation, induction of immunoglobulin secretion, initiation of hepatic acute-phase protein synthesis, and stimulation of hematopoietic precursor cell proliferation and differentiation. Following administration, increases in hemoglobin and decreases in C-reactive protein, rheumatoid factor, erythrocyte sedimentation rate, and serum amyloid A were observed. ANC counts decreased to the nadir 3 to 5 days after administration, and neutrophils recovered toward baseline in a dose-dependent manner. Half-life is concentration dependent and ranges from 11 to 13 days in adults depending on the dose administered. Half-life in pediatric patients ranges from 16 to 17 days.

INDICATIONS AND USES

Treatment of adults with moderately to severely active rheumatoid arthritis who have had an inadequate response to one or more disease-modifying antirheumatic drugs (DMARDs), such as methotrexate, and biologics (e.g., adalimumab, etanercept, infliximab, rituximab). ■ Treatment of patients 2 years of age and older with active polyarticular juvenile idiopathic arthritis (PJIA). ■ Treatment of patients 2 years of age and older with active systemic juvenile idiopathic arthritis (SJIA). ■ Treatment of adult and pediatric patients 2 years of age and older with chimeric antigen receptor (CAR), T-cell–induced, severe or life-threatening cytokine release syndrome. ■ Subcutaneous administration is approved for treatment of adult patients with giant cell arteritis (GCA).

CONTRAINDICATIONS

Known hypersensitivity to tocilizumab.

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patients and respond to any medical emergency. ■ Patients treated with tocilizumab are at increased risk for serious and sometimes fatal infections. Patients were often taking concomitant immunosuppressants such as methotrexate or corticosteroids, which may have predisposed them to infection. The most common serious infections included bacterial arthritis, cellulitis, diverticulitis, gastroenteritis, herpes zoster, pneumonia, sepsis, and UTIs. Reported infections include active tuberculosis (which may present with pulmonary or extrapulmonary disease), invasive fungal infections (e.g., aspergillosis, candidiasis, cryptococcus, pneumocystosis, which may present with disseminated rather than localized disease), and bacterial, viral, and other infections caused by opportunistic pathogens. ■ Do not administer tocilizumab to patients with an active infection, including localized infections. Assess the risks and benefits of tocilizumab before initiating in patients with chronic or recurrent infection, patients who have been exposed to tuberculosis, patients with a history of a serious or an opportunistic infection, patients who have resided or traveled in areas of endemic tuberculosis or endemic mycoses, or patients with underlying conditions that may predispose them to infection. ■ Evaluate patients for TB risk factors and latent TB before initiating therapy; see Monitor. ■ Viral reactivation has been reported with immunosuppressive biologic therapies. Cases of herpes zoster exacerbation have been reported with tocilizumab. Cases of hepatitis B reactivation have not been reported, but patients who screened positive for hepatitis were excluded from studies. ■ Serious cases of hepatic injury have been observed. Some of these cases have resulted in liver transplant and death. Time to onset ranged from months to years after treatment initiation. ■ Has not been studied in patients with active hepatic disease or hepatic impairment, including patients with positive HBV (hepatitis B virus) or HCV (hepatitis C virus) serology. Use is not recommended. ■ Has not been studied in patients with severe renal impairment. ■ Use caution in patients who may be at risk for GI perforation (e.g., diverticulitis) and in patients with pre-existing or recent-onset demyelinating disorders (e.g., multiple sclerosis, chronic inflammatory demyelinating polyneuropathy). ■ Hypersensitivity reactions, including anaphylaxis and death, have been reported. Emergency medical equipment and medications for treating these reactions must be readily available. ■ Tocilizumab is associated with a higher incidence of neutropenia and elevated transaminases, a reduction in platelet counts, and increases in lipids; see Monitor and Dose Adjustments. ■ Infusion-related reactions have occurred; see Side Effects. ■ As with all therapeutic proteins, there is the potential for immunogenicity. ■ Treatment may result in an increased risk of malignancy. ■ Do not administer live virus vaccines. All patients, especially PJIA and SJIA patients and elderly patients, should be brought up-to-date with immunizations before beginning therapy. ■ Patients with severe or life-threatening CRS often have cytopenias or elevated ALT or AST resulting from lymphodepleting chemotherapy or the CRS. The decision to administer should take into account the potential benefit of treating the CRS versus the risk of short-term treatment; see Usual Dose/Pretreatment.

Monitor:

Evaluate patients for TB risk factors and latent TB with a TB skin test before tocilizumab use and during therapy. Patients testing positive in TB screening should be treated with a standard TB regimen before initiating therapy with tocilizumab. Consider treatment in patients with a history of latent or active TB when an adequate course of treatment cannot be confirmed and in patients who have a negative test for latent TB but have risk factors for TB. Consultation with a specialist in TB diagnosis and treatment is encouraged. Closely monitor all patients for S/S of tuberculosis. May present with pulmonary or extrapulmonary disease. ■ Screening for viral hepatitis may be indicated. ■ In RA patients, obtain baseline CBC, platelets, and liver function tests (e.g., ALT, AST, alkaline phosphatase, total bilirubin). ■ Monitor neutrophils and platelets 4 to 8 weeks after start of therapy and then every 3 months thereafter; see Dose Adjustments. ■ Monitor liver function tests every 4 to 8 weeks after start of therapy for the first 6 months and then every 3 months thereafter. Initiating therapy in patients with elevated transaminases ALT or AST greater than 1.5 times the ULN is not recommended; see Dose Adjustment. ■ Measure liver function tests promptly in patients who report symptoms that may indicate liver injury (e.g., anorexia, dark urine, fatigue, jaundice, right upper abdominal discomfort). Interrupt therapy if liver function tests are abnormal. Tocilizumab should be restarted only in patients with another explanation for liver test abnormalities and after normalization of liver tests. ■ In PJIA and SJIA patients, obtain baseline CBC, platelets, and liver function tests. Monitor neutrophils, platelets, ALT, and AST before the second infusion and every 4 to 8 weeks for PJIA and every 2 to 4 weeks for SJIA. ■ In RA, PJIA, and SJIA patients, obtain baseline lipid studies (e.g., cholesterol [HDL, LDL, and total], triglycerides). Repeat in 4 to 8 weeks. Manage patients according to clinical guidelines for management of hyperlipidemia. ■ Closely monitor for S/S of infection during and after treatment with tocilizumab; S/S may be lessened due to suppression of the acute-phase reactants. Hold tocilizumab if a serious infection, an opportunistic infection, or sepsis develops, and appropriate evaluation and treatment should be initiated promptly. ■ Monitor for S/S of hypersensitivity or infusion-related reactions (e.g., anaphylaxis, generalized erythema, hypotension, pruritus, rash, urticaria, or wheezing); most hypersensitivity reactions have occurred between the second and fourth infusion but can occur at any time, even if they have not occurred with earlier infusions. Have occurred in patients who received premedication; see Side Effects. ■ Monitor for S/S of GI perforation (e.g., new-onset abdominal pain). ■ Monitor for S/S potentially indicative of demyelinating disorders. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Read FDA-approved medication guide before starting therapy. ■ Promptly report S/S of an allergic reaction (e.g., rash, itching, wheezing), infusion reaction (e.g., dizziness, headache), or infection (e.g., chill, cough, with or without a fever). Report severe, persistent abdominal pain promptly. ■ Discuss previous infections, current infections, or exposure to TB. ■ May cause fetal harm. Report suspected or known pregnancy. Pregnancy registry has been established. ■ Routine laboratory monitoring required. ■ All vaccinations should be brought up-to-date before starting tocilizumab.

Maternal/Child:

Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. Monoclonal antibodies are increasingly transported across the placenta as pregnancy progresses, with the largest amount transferred during the third trimester. ■ A pregnancy registry has been established; contact manufacturer. ■ Consider risk versus benefit with breast-feeding. ■ Safety and effectiveness have been established for use only in pediatric patients 2 years of age or older with SJIA, PJIA, and CRS. ■ Risks and benefits should be considered before administering live or live-attenuated vaccines to infants exposed to tocilizumab in utero.

Elderly:

Incidence of infection is higher in elderly patients. Clinical studies for CRS did not include sufficient numbers of patients 65 years of age and older to determine whether they respond differently from younger patients. Use caution; see Precautions.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Avoid concurrent use with **biological DMARDS** such as TNF antagonists (e.g., adalimumab, etanercept, infliximab), IL-1R antagonists, anti-CD20 monoclonal antibodies, and selective costimulation modulators; may increase immunosuppression and risk of infection. ■ Increased frequency and magnitude of LFT elevations may be seen when tocilizumab is coadministered with other potentially **hepatotoxic medications** (e.g., methotrexate). ■ Inhibition of IL-6 signaling in patients treated with tocilizumab may restore CYP450 activities to higher levels, resulting in an increased metabolism of drugs that are CYP450 substrates. Concurrent use showed an increase in metabolism and lower serum concentrations of **omeprazole** and **simvastatin**. This effect may be clinically relevant with CYP450 substrates with a narrow therapeutic index, in which the dose is individually adjusted (e.g., **warfarin**, **cyclosporine**, **theophylline**). Therapeutic monitoring of effect (INR) and/or serum concentrations is indicated to adjust the dose of these drugs with initiation or termination of tocilizumab. Use caution with CYP3A4 substrate drugs in which a decrease in effectiveness is undesirable (e.g., **atorvastatin, oral contraceptives**). The effect of tocilizumab on CYP450 enzyme activity may persist for several weeks after therapy is discontinued. ■ Do not administer **live virus vaccines.**

SIDE EFFECTS

RA:

The most common adverse reactions include headache, hypertension, increased ALT, injection site reactions, nasopharyngitis, and upper respiratory tract infections. The most common serious infections include bacterial arthritis, cellulitis, diverticulitis, gastroenteritis, herpes zoster, pneumonia, sepsis, and UTIs. The most common side effects that required discontinuation of therapy were increased hepatic transaminase values and serious infections. Infusion-related reactions have been reported. Hypertension frequently occurred during infusion, and headache and skin reactions (e.g., pruritus, rash, urticaria) were reported within the next 24 hours. Hypersensitivity reactions (e.g., anaphylactoid and anaphylactic) did occur in a few patients. Other side effects reported include bronchitis, conjunctivitis, cough, dizziness, dyspnea, elevated lipids, gastric ulcer, gastritis, GI perforation (seen primarily in patients taking concomitant NSAIDs, corticosteroids, or methotrexate), hypothyroidism, increased total bilirubin, increased weight, leukopenia, mouth ulceration, nephrolithiasis, neutropenia, oral herpes simplex, peripheral edema, stomatitis, thrombocytopenia, and upper abdominal pain.

PJIA:

Side effects consistent with those seen in RA and SJIA patients.

SJIA:

The most common adverse reactions included diarrhea, headache, nasopharyngitis, and upper respiratory tract infections. Anaphylaxis, decreased platelet count, development of anti-tocilizumab antibodies, increased liver function tests and lipids, infections, infusion reactions, macrophage activation syndrome (MAS), and neutropenia have been reported.

CRS:

No adverse reactions related to tocilizumab were reported in a retrospective analysis.

Post-Marketing:

Drug-induced liver injury, fatal anaphylaxis, hepatitis, hepatic failure, jaundice, pancreatitis, Stevens-Johnson syndrome.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. During clinical studies, most infusion-related reactions were mild to moderate. Interrupt therapy for decreases in ANC and platelets and increases in liver function studies as outlined in Dose Adjustments. Therapy may need to be interrupted in patients who develop infections. Discontinue tocilizumab for any serious reaction or infection. Treat infusion and hypersensitivity reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Resuscitate as necessary.

TOPOTECAN HYDROCHLORIDE BBW

(toh-poh-**TEE**-kan hy-droh-**KLOR**-eyed)
Hycamtin
Antineoplastic (topoisomerase I inhibitor)
pH 2.5 to 3.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Verify dose using body surface area before dispensing. Recommended dose should generally not exceed 4 mg IV. Before giving the initial dose, the baseline neutrophil count must be at least 1,500/mm^3 and baseline platelet count must be at least 100,000/mm^3.

Ovarian cancer and small-cell lung cancer:

1.5 mg/M^2 as an infusion each day for 5 consecutive days (Days 1 through 5 of a 21-day course). Begin the second course on Day 22. See Dose Adjustments.

Cervical cancer:

0.75 mg/M^2 as an infusion on Days 1, 2, and 3. On Day 1 follow with cisplatin 50 mg/M^2. Repeat every 21 days. See cisplatin monograph for prehydration requirements.

Non–small-cell lung cancer (unlabeled):

1.5 mg/M^2 as an infusion each day for 5 consecutive days. Repeat every 21 days.

DOSE ADJUSTMENTS

Do not begin subsequent courses of topotecan until neutrophils recover to more than 1,000/mm^3, platelets recover to 100,000/mm^3, and hemoglobin recovers to 9 mg/dL (with transfusion if necessary). ■ **For single-agent use,** reduce dose to 1.25 mg/M^2 for (1) neutrophil counts less than 500 cells/mm^3, or administer granulocyte-colony stimulating factor (G-CSF) starting no sooner than 24 hours after the last dose of topotecan; or (2) platelet counts less than 25,000 cells/mm^3 during the previous cycle. ■ **For combination use with cisplatin,** reduce dose to 0.6 mg/M^2 (and further to 0.45 mg/M^2 if necessary) for (1) febrile neutropenia (defined as neutrophil counts less than 1,000 cells/mm³ with temperature greater than or equal to 38° C [100.4° F]), or administer G-CSF starting no sooner than 24 hours after the last dose of topotecan; or (2) platelet counts less than 25,000 cells/mm³ during the previous cycle. See cisplatin monograph for specific dose adjustments. ■ **For single-agent use,** reduce dose to 0.75 mg/M² in patients with moderate impaired renal function (CrCl 20 to 39 mL/min). There are inadequate data at this time to recommend a dose in severe renal impairment. ■ Dose adjustment may be required in the elderly because of age-related renal impairment.

DILUTION

Specific techniques required; see Precautions. Available as a 4-mg lyophilized powder in a single-dose vial. Reconstitute each 4-mg vial with 4 mL of SWFI (1 mg/mL). Also available as a generic in a 4 mg/4 mL solution in a single-use vial. Withdraw the calculated dose and further dilute in NS or D5W.

Filters:

No data available from manufacturer.

Storage:

Hycamtin:

Store unopened vials in cartons protected from light between 20° and 25° C (68° and 77° F). Reconstituted solutions contain no preservative; use immediately. Solutions diluted for infusion are stable at room temperature in soft light for 24 hours. ***Generic:*** Store unopened vials in cartons protected from light and refrigerated between 2° and 8° C (36° and 46° F). Solutions diluted for infusion are stable for no more than 4 hours at RT or for 12 hours if refrigerated.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion evenly distributed over 30 minutes.

ACTIONS

A class of antineoplastic agent that inhibits the enzyme topoisomerase I required for DNA replication. It is a semi-synthetic derivative of camptothecin. Causes cell death by damaging DNA produced during the S-phase of the cell cycle. Undergoes pH-dependent hydrolysis in plasma, and minor additional metabolism occurs in the liver. Terminal half-life is 2 to 3 hours. Moderately bound to plasma protein (35%). Excreted in urine and, to a lesser extent, in feces.

INDICATIONS AND USES

As a single agent for treatment of patients with metastatic carcinoma of the ovary after disease progression on or after initial or subsequent chemotherapy. ■ As a single agent for treatment of patients with small-cell lung cancer with platinum-sensitive disease who progressed at least 60 days after initiation of first-line chemotherapy. ■ In combination with cisplatin for treatment of patients with stage IV-B, recurrent, or persistent carcinoma of the cervix not amenable to curative treatment.

Unlabeled uses:

Treatment of non–small-cell lung cancer.

CONTRAINDICATIONS

History of severe hypersensitivity reactions to topotecan.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be available to meet any medical emergency. ■ May cause severe myelosuppression. Bone marrow suppression (primarily neutropenia) is the dose-limiting toxicity. Severe myelotoxicity has been reported when topotecan is administered in combination with cisplatin. Anemia, neutropenia, febrile neutropenia, pancytopenia, and thrombocytopenia have been reported; see Monitor. ■ Use with caution in impaired renal function; clearance decreased. ■ Neutropenic enterocolitis (typhlitis) has been reported. Fatalities have occurred; see Monitor. ■ Interstitial lung disease (ILD), including fatalities, has occurred; risk increased in patients with a history of ILD, lung cancer, pulmonary fibrosis, thoracic irradiation, and the use of pneumotoxic drugs and/or colony-stimulating factors; see Monitor.

Monitor:

Baseline neutrophil count must be at least 1,500/mm^3 and platelets at least 100,000/mm^3 before the initial dose. ■ Obtain a baseline CBC with differential and platelets. ■ Monitor before each course and frequently during treatment. Platelet count must be 100,000/mm^3, neutrophils 1,000/mm^3, and hemoglobin 9 mg/dL before a course of therapy can be repeated. Anemia is frequent and transfusion is often indicated. ■ Baseline CrCl and BUN suggested. ■ Monitor vital signs. ■ Maintain adequate hydration. ■ Nausea and vomiting can be frequent and may be severe; use prophylactic administration of antiemetics to increase patient comfort. ■ Observe closely for S/S of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Not a vesicant, but monitor injection site for inflammation and/or extravasation. Severe cases have been reported. If S/S of extravasation occur, discontinue infusion and manage as indicated. ■ Monitor for S/S of ILD (e.g., cough, dyspnea, fever, and/or hypoxia). ■ Monitor for signs of neutropenic colitis (e.g., fever, neutropenia, and abdominal pain). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Platelet transfusions may be required. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Females should use effective contraception during treatment and for at least 1 month after the last dose of topotecan. ■ May damage spermatozoa. Males with a female sexual partner of reproductive potential should use effective contraception during and for 3 months after treatment with topotecan. ■ Potential risk for impaired fertility in both male and female patients. Discuss family planning options if appropriate. ■ Report any unusual or unexpected symptoms or side effects as soon as possible (e.g., signs of infection [e.g., chills, fever, night sweats] or signs of bleeding [e.g., bruising, black tarry stools]). ■ May cause loss of strength or fatigue. Use caution when driving or operating machinery. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy; can cause fetal harm; see Patient Education. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Safety and effectiveness similar to younger adults. ■ Consider age-related renal impairment; see Dose Adjustments. Monitoring of renal function may be useful.

DRUG/LAB INTERACTIONS

May cause severe prolonged myelosuppression and Grade 3 or 4 nonhematologic effects (e.g., diarrhea, lethargy, nausea, vomiting) with **cisplatin.** ■ Concurrent administration of **G-CSF (filgrastim)** can prolong the duration of neutropenia. If used, do not administer until at least 24 hours after the final dose of topotecan. ■ Concurrent or consecutive administration of **other bone marrow suppressants** (e.g., cyclophosphamide, paclitaxel) **or radiation therapy** may produce additive bone marrow suppression. Dose reduction may be required based on blood cell counts. ■ Concurrent use with **hydantoins** (e.g., phenytoin) may decrease plasma concentrations of topotecan. Specific guidelines for topotecan dose adjustment are not available. Consider alternatives to phenytoin when possible. ■ Do not administer **palifermin** within 24 hours before or after topotecan; coadministration may increase the severity and duration of oral mucositis. ■ Do not administer **live virus vaccines.**

SIDE EFFECTS

Bone marrow suppression, primarily neutropenia, is the dose-limiting toxicity of topotecan.

Ovarian cancer:

The most common hematologic adverse reactions were anemia (Grade 3 and 4), febrile neutropenia, neutropenia (Grade 4), and thrombocytopenia (Grade 4). The most common nonhematologic adverse reactions were diarrhea, dyspnea, fatigue, nausea, and vomiting. Other reported reactions included abdominal pain, asthenia, constipation, elevated bilirubin and hepatic enzymes, intestinal obstruction, pain, and sepsis.

Small-cell lung cancer:

The most common hematologic adverse reactions were anemia (Grade 3 and 4), febrile neutropenia, neutropenia (Grade 4), and thrombocytopenia (Grade 4). The most common nonhematologic adverse reactions were abdominal pain, asthenia, dyspnea, fatigue, nausea, and pneumonia. Other reported reactions included elevated bilirubin and hepatic enzymes, pain, and sepsis.

Cervical cancer:

The most common hematologic adverse reactions were anemia (Grade 3 and 4), neutropenia (Grade 3 and 4), and thrombocytopenia (Grade 3 and 4). The most common nonhematologic adverse reactions were infection/febrile neutropenia, pain, and vomiting. Other reported reactions included asthenia, chills, fatigue, fever, lethargy, malaise, rigors, stomatitis-pharyngitis, sweating, and weight gain or loss.

Post-Marketing:

Abdominal pain associated with neutropenic enterocolitis, extravasation, hypersensitivity reactions (including anaphylaxis), interstitial lung disease, severe bleeding, skin and subcutaneous tissue disorders (e.g., angioedema, severe dermatitis, severe pruritus).

ANTIDOTE

Keep physician informed of all side effects. Withhold topotecan until myelosuppression has improved to minimum requirements. Neutropenia recovery may be aided by G-CSF (filgrastim, pegfilgrastim) under specific conditions; see Dose Adjustments or Drug/Lab Interactions. Anemia often required RBC or whole blood transfusions. Thrombocytopenia may require platelet transfusion. Death can result from the progression of many side effects. Discontinue topotecan if a new diagnosis of ILD is confirmed. No known antidote for overdose. If an overdose is suspected, monitor for bone marrow suppression and institute supportive care measures (e.g., prophylactic G-CSF and antibiotic therapy) as appropriate. Treat hypersensitivity reactions with oxygen, epinephrine, corticosteroids, and antihistamines.

TRABECTEDIN

(tra-**BEK**-te-din)
Yondelis
Antineoplastic
(alkylating agent)
pH 3.6 to 4.2

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies and pretesting required; see Monitor.

Premedication:

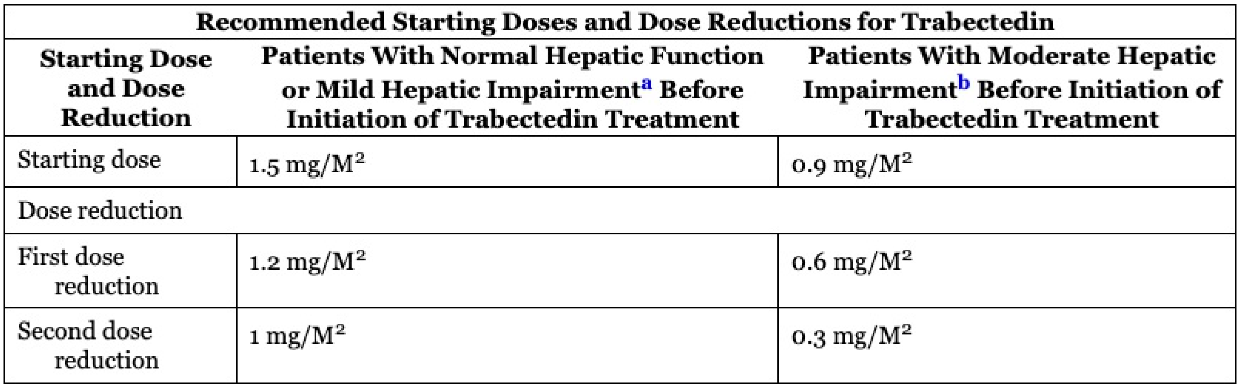
Dexamethasone 20 mg IV 30 minutes before each dose of trabectedin.

Trabectedin:

1.5 mg/M^2 administered as an infusion over 24 hours through a central venous line every 21 days (3 weeks), until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

Reduce dose to 0.9 mg/M^2 in patients with moderate hepatic impairment (bilirubin levels 1.5 to 3 times the ULN, and AST and ALT less than 8 times the ULN). Do not administer to patients with severe hepatic impairment (bilirubin levels above 3 to 10 times the ULN, and any AST and ALT). ■ No dose adjustment is recommended in patients with mild (CrCl 60 to 89 mL/min) or moderate (CrCl 30 to 59 mL/min) renal impairment or mild hepatic impairment. ■ The recommended starting doses and dose reductions for trabectedin are listed in the following chart.

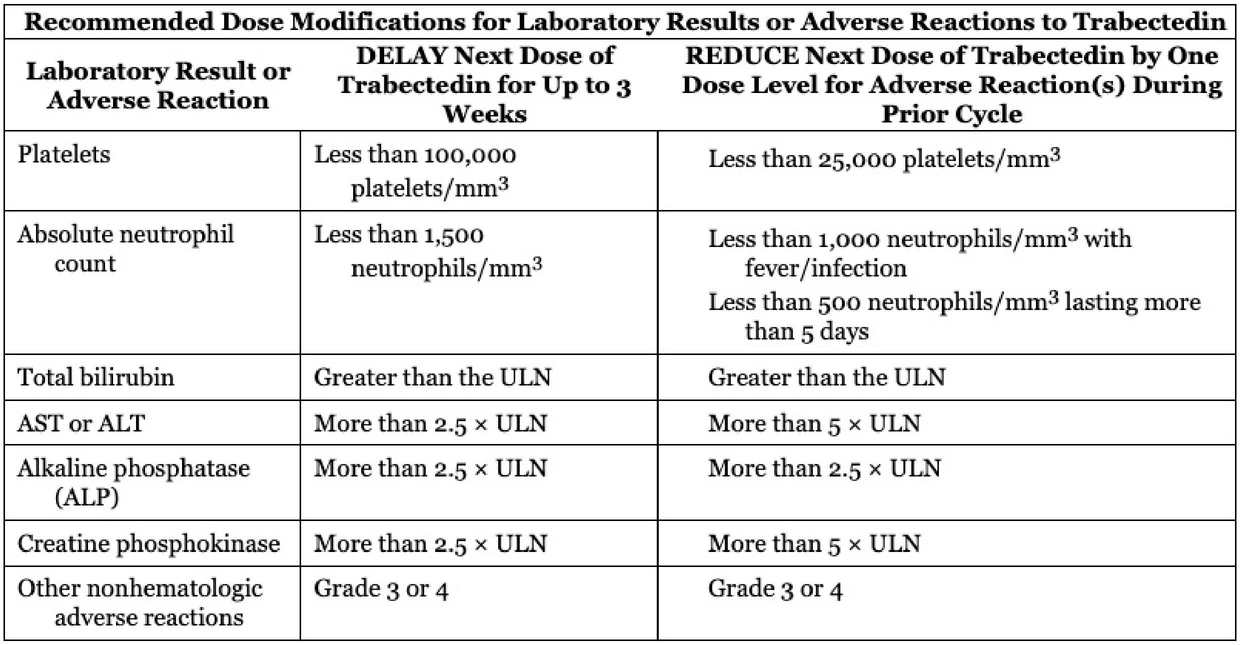


Recommended Starting Doses and Dose Reductions for Trabectedin		
Starting Dose and Dose Reduction	**Patients With Normal Hepatic Function or Mild Hepatic Impairment[a] Before Initiation of Trabectedin Treatment**	**Patients With Moderate Hepatic Impairment[b] Before Initiation of Trabectedin Treatment**
Starting dose	1.5 mg/M^2	0.9 mg/M^2
Dose reduction		
First dose reduction	1.2 mg/M^2	0.6 mg/M^2
Second dose reduction	1 mg/M^2	0.3 mg/M^2

[a] Including patients with bilirubin 1 to 1.5 times the ULN and any AST or ALT.

[b] Including patients with bilirubin greater than 1.5 to 3 times the ULN, and AST or ALT less than 8 times the ULN.

Once reduced, the dose of trabectedin should not be increased in subsequent treatment cycles. ■ Recommended dose modifications for laboratory results and adverse reactions are listed in the following chart.



Recommended Dose Modifications for Laboratory Results or Adverse Reactions to Trabectedin		
Laboratory Result or Adverse Reaction	**DELAY Next Dose of Trabectedin for Up to 3 Weeks**	**REDUCE Next Dose of Trabectedin by One Dose Level for Adverse Reaction(s) During Prior Cycle**
Platelets	Less than 100,000 platelets/mm^3	Less than 25,000 platelets/mm^3
Absolute neutrophil count	Less than 1,500 neutrophils/mm^3	Less than 1,000 neutrophils/mm^3 with fever/infection Less than 500 neutrophils/mm^3 lasting more than 5 days
Total bilirubin	Greater than the ULN	Greater than the ULN
AST or ALT	More than 2.5 × ULN	More than 5 × ULN
Alkaline phosphatase (ALP)	More than 2.5 × ULN	More than 2.5 × ULN
Creatine phosphokinase	More than 2.5 × ULN	More than 5 × ULN
Other nonhematologic adverse reactions	Grade 3 or 4	Grade 3 or 4

- Permanently discontinue trabectedin for (1) persistent adverse reactions requiring a delay in dosing of more than 3 weeks, (2) adverse reactions requiring a dose reduction after trabectedin administration at 1 mg/M^2 for patients with normal hepatic function or at 0.3 mg/M^2 for patients with pre-existing moderate hepatic impairment, (3) severe liver dysfunction: bilirubin 2 times the ULN and AST or ALT 3 times the ULN with alkaline phosphatase less than 2 times the ULN in the previous treatment cycle for patients with normal liver function at baseline, (4) exacerbation of liver dysfunction in patients with pre-existing moderate hepatic impairment, (5) capillary leak syndrome, (6) rhabdomyolysis, or (7) Grade 3 or 4 cardiac adverse events indicative of cardiomyopathy or for subjects with LVEF that decreases below the lower limit of normal.

DILUTION

Specific techniques required; see Precautions. Available as a lyophilized powder in a single-dose vial containing 1 mg of trabectedin. Using aseptic technique, inject 20 mL of SWFI into the vial. Shake the vial until complete dissolution. The reconstituted solution is clear, colorless to pale brownish-yellow, and contains 0.05 mg/mL of trabectedin. Inspect for particulate matter and discoloration before further dilution. Discard vial if particles or discoloration are observed. Immediately following reconstitution, withdraw the calculated volume of trabectedin and further dilute in 500 mL of NS or D5W.

Filters:

Use of a 0.2-micron polyethersulfone (PES) in-line filter is recommended to reduce the risk of exposure to adventitious pathogens that may be introduced during solution preparation.

Storage:

Before use, store vials in a refrigerator at 2° to 8° C (36° to 46° F). Discard any unused portion of the reconstituted solution, and discard any remaining diluted solution within 30 hours of reconstituting the lyophilized powder.

COMPATIBILITY

Manufacturer states, “Do not mix trabectedin with other drugs.” Trabectedin diluted solution is **compatible** with Type I colorless glass vials; polyvinylchloride (PVC) and polyethylene (PE) bags and tubing; PE and polypropylene (PP) mixture bags; polyethersulfone (PES) in-line filters; titanium, platinum, or plastic ports; silicone and polyurethane catheters; and pumps having contact surfaces made of PVC, PE, or PE/PP.

RATE OF ADMINISTRATION

Infuse the reconstituted, diluted solution over 24 hours through a central venous line using an infusion set with a 0.2-micron PES in-line filter. Complete infusion within 30 hours of initial reconstitution.

ACTIONS

Trabectedin is an alkylating drug that binds guanine residues in the minor groove of DNA, forming adducts and resulting in a bending of the DNA helix toward the major groove. Adduct formation triggers a cascade of events that can affect the subsequent activity of DNA binding proteins, resulting in perturbation of the cell cycle and eventual cell death. Highly protein bound (97%). Terminal elimination half-life is approximately 175 hours. No accumulation in plasma is observed with repeated administrations every 3 weeks. Extensively metabolized with negligible unchanged drug in urine and feces following administration.

INDICATIONS AND USES

Treatment of patients with unresectable or metastatic liposarcoma or leiomyosarcoma who received a prior anthracycline-containing regimen.

CONTRAINDICATIONS

Known severe hypersensitivity, including anaphylaxis, to trabectedin.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Neutropenic sepsis, including fatal cases, can occur. Grade 3 or 4 neutropenia, febrile neutropenia, and sepsis have been reported. ■ Rhabdomyolysis and musculoskeletal toxicity have occurred. Has led to renal failure and death in some cases. ■ Hepatotoxicity, including hepatic failure, has occurred. Patients with serum bilirubin levels above the ULN or AST or ALT levels greater than 2.5 times the ULN were excluded from clinical trials. ■ Cardiomyopathy, including cardiac failure, congestive heart failure, decreased ejection fraction, diastolic dysfunction, or right ventricular dysfunction, has been reported. Patients with LVEF less than the lower limit of normal, prior cumulative anthracycline doses of 300 mg/M^2 or greater, age 65 years or older, or a history of cardiovascular disease may be at increased risk of cardiac dysfunction. Patients with a history of New York Heart Association Class II to IV heart failure or abnormal left ventricular ejection fraction (LVEF) at baseline were excluded from clinical trials. ■ Capillary leak syndrome (CLS) characterized by edema, hypoalbuminemia, and hypotension has been reported. Serious CLS resulting in death has occurred. ■ Extravasation resulting in tissue necrosis and requiring debridement can occur. Evidence of tissue necrosis can occur more than 1 week after the extravasation. Use of a central venous line required.

Monitor:

Premedication required; see Usual Dose. ■ Obtain baseline CBC with differential and platelets, and liver function tests (LFTs). ■ Obtain CBC, including differential and platelet count, before each dose of trabectedin and periodically throughout the treatment cycle. Withhold trabectedin for neutrophil counts of less than 1,500 cells/mm^3 on the day of dosing. Permanently reduce the dose of trabectedin for life-threatening or prolonged, severe neutropenia in the preceding cycle; see Dose Adjustments. ■ Obtain creatine phosphokinase (CPK) levels before each dose of trabectedin. Withhold trabectedin for serum CPK levels more than 2.5 times the ULN. Permanently discontinue trabectedin if rhabdomyolysis occurs; see Dose Adjustments. ■ Assess LFTs before each dose of trabectedin and as clinically indicated based on underlying severity of pre-existing hepatic impairment. Monitor for S/S of hepatotoxicity (e.g., abdominal pain [upper right], jaundice, lethargy, nausea, vomiting). Manage elevated LFTs with treatment interruption, dose reduction, or permanent discontinuation based on severity and duration of LFT abnormality; see Dose Adjustments. ■ Assess left ventricular ejection fraction (LVEF) by echocardiogram or multigated acquisition (MUGA) scan before initiation of trabectedin and at 2- to 3-month intervals thereafter until trabectedin is discontinued. Monitor for S/S of cardiomyopathy (e.g., chest pain; dyspnea; edema of the legs, ankles, or feet; heart palpitations). Permanently discontinue trabectedin for Grade 3 or 4 cardiac adverse events indicative of cardiomyopathy or for subjects with an LVEF that decreases below the lower limit of normal; see Dose Adjustments. ■ Monitor for S/S of CLS (e.g., edema, hypoalbuminemia, and hypotension). Discontinue trabectedin and promptly initiate management for patients with CLS. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, hypotension, pruritus, rash, urticaria, or wheezing). ■ Monitor IV site for any sign of extravasation. ■ Effects of severe renal impairment, or ESRD on trabectedin exposure is unknown.

Patient Education:

Review manufacturer's medication guide. ■ Females of reproductive potential must use effective contraception during therapy and for at least 2 months after the last dose of trabectedin. Notify your health care provider if you become pregnant or suspect a pregnancy. ■ Males with female partners of reproductive potential must use effective contraception during therapy and for at least 5 months after the last dose of trabectedin.

May damage spermatozoa, resulting in possible genetic and fetal abnormalities. ■ May result in decreased fertility in males and females. ■ Immediately report S/S of a hypersensitivity reaction (e.g., difficulty breathing, chest tightness, wheezing, severe dizziness or light-headedness, swelling of the lips, or skin rash). ■ Promptly report discomfort, itchiness, leaking, redness, or swelling at the injection site. ■ Promptly report fever, unusual bruising, bleeding, severe muscle pain or weakness, tiredness, or paleness. ■ Promptly report S/S of CLS (e.g., dizziness, light-headedness with or without a sudden drop in blood pressure, and swelling). ■ Promptly report S/S of hepatotoxicity (e.g., yellowing of the skin and eyes [jaundice], pain in the upper right quadrant, severe nausea or vomiting, difficulty concentrating, disorientation, or confusion). ■ Promptly report new-onset chest pain, shortness of breath, fatigue, lower extremity edema, or heart palpitations. ■ See Appendix D.

Maternal/Child:

Based on its mechanism of action, trabectedin can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Numbers insufficient to determine differences in response in elderly patients compared with younger adults.

DRUG/LAB INTERACTIONS

Coadministration of trabectedin with **strong CYP3A inhibitors** increases the systemic exposure of trabectedin. Avoid the use of strong CYP3A inhibitors (e.g., boceprevir [Victrelis], clarithromycin [Biaxin], conivaptan [Vaprisol], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], lopinavir/ritonavir [Kaletra], nefazodone, nelfinavir [Viracept], posaconazole [Noxafil], ritonavir [Norvir], saquinavir [Invirase], telaprevir [Incivek], telithromycin [Ketek], and voriconazole [VFEND]). If a **strong CYP3A inhibitor** must be used for a short time (fewer than 14 days), wait to administer until 1 week after the trabectedin infusion, and discontinue the day before the next scheduled infusion. ■ Coadministration with **strong CYP3A inducers** decreases the systemic exposure of trabectedin. Avoid the use of strong CYP3A inducers (e.g., phenobarbital [Luminal], rifampin [Rifadin], St. John’s wort).

SIDE EFFECTS

The most common adverse reactions are constipation, decreased appetite, diarrhea, dyspnea, fatigue, headache, nausea, peripheral edema, and vomiting. Other clinically important adverse reactions include hypoesthesia, paresthesia, peripheral neuropathy, and pulmonary embolism. The most common laboratory abnormalities are anemia; hypoalbuminemia; increased AST, ALT, alkaline phosphatase, CPK, and creatinine; neutropenia; and thrombocytopenia. The most common adverse reactions resulting in permanent discontinuation of trabectedin in clinical trials were decreased ejection fraction, fatigue, increased creatine phosphokinase, liver function tests, and thrombocytopenia.

Post-Marketing:

Capillary leak syndrome.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Withhold or discontinue trabectedin based on adverse reaction or clinical picture as indicated in Dose Adjustments. Discontinue administration at the first sign of a serious hypersensitivity reaction and treat as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). See Precautions and Monitor. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen, Zarxio], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. There is no specific antidote for trabectedin. Hemodialysis is not expected to enhance the elimination of trabectedin because trabectedin is highly bound to plasma proteins and not significantly renally excreted. Resuscitate as indicated.

USUAL DOSE

Available as single elements, selected combined elements in various strengths, and in combination with electrolytes. *Some preparations may contain aluminum; see Precautions*. Selection of correct product based on minimum daily requirement and individual needs.

Chromium:

10 to 15 mcg/day. Increase to 20 mcg/day with intestinal fluid loss.

Copper:

0.5 to 1.5 mg/day.

Iodine:

1 to 2 mcg/kg of body weight/day. Increase to 2 to 3 mcg/kg/day in growing children, pregnant and lactating women.

Manganese:

0.15 to 0.8 mg/day. May contain up to 100 mcg/L of aluminum; see Precautions.

Molybdenum:

20 to 120 mcg/day. Increase to 163 mcg/day for 21 days in deficiency states resulting from prolonged TPN.

Selenium:

20 to 40 mcg/day. Increase to 100 mcg/day for 31 days in deficiency states resulting from prolonged TPN.

Zinc:

2.5 to 4 mg/day; add 2 mg in acute catabolic states. Increase to 12.2 mg/L of total parenteral nutrition (TPN) if there is fluid loss from the small bowel. May contain aluminum.

PEDIATRIC DOSE

Chromium:

0.14 to 0.2 mcg/kg/day.

Copper:

20 mcg/kg/day.

Manganese:

2 to 10 mcg/kg/day. May contain up to 100 mcg/L of aluminum; see Precautions.

Molybdenum:

Must calculate dosage by extrapolation; consult pharmacist.

Selenium:

3 mcg/kg/day.

Zinc:

100 mcg/kg/day for full-term infants and other pediatric patients up to 5 years of age. 300 mcg/kg/day for premature infants with birth weights from 1,500 Gm to 3 kg. May contain aluminum.

DOSE ADJUSTMENTS

Reduce or omit dose in impaired renal function. ■ Caution and lower-end dosing may be appropriate in the elderly; consider decreased organ function and concomitant disease or drug therapy.

DILUTION

Must be added to daily volume of IV infusion fluids including TPN. Check labels for aluminum content; see Precautions.

COMPATIBILITY

Specific trace metals may present **compatibility** problems. Check **incompatibilities** of each agent to be admixed or delivered to the **Y-site.** Consult a pharmacist.

RATE OF ADMINISTRATION

Administer properly diluted at rate prescribed for IV infusion fluids or TPN.

ACTIONS

All are basic elements present in the human body. Specific amounts required to initiate, facilitate, or maintain appropriate body systems.

INDICATIONS AND USES

Nutritional supplement to IV solutions given for total parenteral or central nutrition.

CONTRAINDICATIONS

Do not give direct IV; hypersensitivity to any component (especially iodides). Manganese contraindicated in presence of high manganese levels. Molybdenum without copper supplementation contraindicated in copper-deficient patients.

PRECAUTIONS

Selenium enhances vitamin E and decreases the toxicity of mercury, cadmium, and arsenic. ■ Patients with biliary tract obstruction may retain copper and manganese. ■ Avoid copper in patients with Wilson’s disease (genetic disorder of copper metabolism). ■ Assess possibility of diabetes mellitus when giving chromium supplements to maintain normal glucose metabolism. ■ Some solutions may contain aluminum (e.g., manganese, zinc). In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation.

Monitor:

Monitor serum trace metal concentration to avoid accumulation. Results will also determine use of a single element or a combined product.

Maternal/Child:

Category C: use in pregnancy only if clearly indicated. Use manganese with caution in the nursing mother. ■ May contain benzyl alcohol; may cause fatal “gasping” syndrome in premature infants.

Elderly:

Differences in response compared to younger adults not identified. ■ Dosing should be cautious; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Therapeutic serum levels of **copper and zinc** will decrease if not given together.

SIDE EFFECTS

Toxicity is rare at recommended doses. Iodine may cause anaphylaxis.

ANTIDOTE

Dosage will be adjusted based on serum levels. Keep physician informed. Resuscitate as necessary.

TRANEXAMIC ACID

(**TRAN**-eks-am-ik **AS**-id)
Cyklokapron
Antifibrinolytic
Antihemorrhagic
pH 6.5 to 8

USUAL DOSE

Dental extraction in adults and pediatric patients with hemophilia:

Preoperative: Normal renal function required. 10 mg/kg IV immediately before surgery. ***Postoperative:*** 10 mg/kg IV every 6 to 8 hours for 2 to 8 days.

Trauma-associated hemorrhage (unlabeled):

A loading dose of 1,000 mg IV over 10 minutes followed by an infusion of 1,000 mg over 8 hours. Treatment should begin within 8 hours of injury.

Total knee replacement surgery, blood loss reduction (unlabeled):

Several regimens have been studied and include:

10 mg/kg IV over 30 minutes before inflation of the tourniquet followed by 10 mg/kg IV 3 hours after the first dose

OR

10 mg/kg IV administered 30 minutes before deflation of the tourniquet followed by an infusion of 1 mg/kg/hr. Infusion begins at the end of surgery and continues for 6 hours postoperatively.

DOSE ADJUSTMENTS

Lower-end initial and/or reduced doses may be indicated in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy. ■ Reduce dose in impaired renal function according to the following chart.

Tranexamic Dose Guidelines in Impaired Renal Function

Serum Creatinine (mg/dL)	Dose
1.36-2.83 mg/dL	10 mg/kg two times per day
2.83-5.66 mg/dL	10 mg/kg once per day
>5.66 mg/dL	10 mg/kg every 48 hours or 5 mg/kg every 24 hours

DILUTION

100 mg equals 1 mL of prepared solution. Further dilute a single dose with at least 50 mL **compatible** infusion solutions (e.g., NS, dextrose solutions in water or various concentrations of NS); see Compatibility. Prepare solution immediately before use; discard any unused solution.

Storage:

Store ampules at CRT. Prepare the same day it is to be administered.

COMPATIBILITY

Do not mix with blood and do not mix with solutions containing penicillins. See Drug/Lab Interactions.

Solutions:

May be mixed with IV solutions, including solutions containing electrolytes, carbohydrates, amino acids, or dextran.

Additive:

Compatible with heparin.

RATE OF ADMINISTRATION

100 mg or fraction thereof over at least 1 minute. Too-rapid infusion may cause hypotension.

ACTIONS

An inhibitor of fibrinolysis. Inhibits plasminogen activation and, at higher concentrations, inhibits plasmin. About 10 times more potent than aminocaproic acid. Onset of action is prompt. Half-life approximately 2 hours. Excreted in urine primarily as unchanged drug. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Reduce or prevent hemorrhage and reduce the need for replacement therapy in hemophilia patients during and following tooth extraction.

Unlabeled uses:

Trauma-associated hemorrhage, prevention of perioperative bleeding associated with cardiac surgery and spinal surgery, reduction of blood loss associated with orthopedic surgery or cesarean section.

CONTRAINDICATIONS

Acquired defective color vision, active intravascular clotting, subarachnoid hemorrhage, and hypersensitivity to tranexamic acid or its ingredients.

PRECAUTIONS

For short-term use only (2 to 8 days). ■ Focal areas of retinal degeneration have been seen in animals, and visual abnormalities have been noted in post-marketing reports; see Monitor. ■ Rapid administration in any form may cause hypotension. ■ Whole blood transfusions may be given if necessary but must be given through a second infusion site. ■ In patients with upper urinary tract bleeding, ureteral obstruction due to clot formation has been reported. ■ Risk of venous or arterial thrombosis increased in patients with a previous history of thromboembolic disease. ■ Thromboembolic events (e.g., central retinal artery and vein obstruction, cerebral thrombosis, deep vein thrombosis, pulmonary embolism) have been reported rarely in patients receiving tranexamic acid for indications other than hemorrhage prevention in patients with hemophilia. ■ Patients with DIC being treated with tranexamic acid require the strict supervision of a physician specialist. ■ Convulsions have been reported with tranexamic acid treatment. ■ See Compatibility and Drug/Lab Interactions.

Monitor:

Use only in conjunction with general and specific tests to determine the amount of fibrinolysis present. ■ In repeated treatment or if treatment will last more than several (2 to 3) days, a complete ophthalmologic examination (visual acuity, color vision, eyeground, visual fields) should be done before and at regular intervals during treatment. Discontinue use if changes are found.

Patient Education:

May produce dizziness; request assistance with ambulation and use caution performing tasks that require alertness (e.g., driving or operating machinery).

Maternal/Child:

Category B: use caution and only if clearly needed in pregnancy and breast-feeding. ■ Use in pediatric patients has been limited. Available data suggest that the mg/kg dose for adults can be used.

Elderly:

Lower-end initial or reduced doses may be indicated; see Dose Adjustments. ■ Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

No formal Drug Interaction studies between tranexamic acid and other drugs have been conducted. ■ Concomitant use with **factor IX complex** (e.g., AlphaNine SD, Mononine, Konyne) or **anti-inhibitor coagulant concentrates** (e.g., Feiba) is not recommended; may increase the risk for venous or arterial thrombosis.

SIDE EFFECTS

Allergic dermatitis, diarrhea, giddiness, hypotension, nausea and vomiting. Thromboembolic events (e.g., central retinal artery and vein obstruction, cerebral thrombosis, deep vein thrombosis, pulmonary embolism) have been reported rarely.

Post-Marketing:

Chromatopsia and visual impairment, convulsions, and thromboembolic events as above have been reported.

ANTIDOTE

All side effects may subside with reduced dosage or rate of administration. Discontinue use of drug if any changes are found during follow-up ophthalmologic examinations. Resuscitate as necessary.

TRASTUZUMAB BBW ■ TRASTUZUMAB-dkst[a] BBW ■ TRASTUZUMAB-dttb[a] BBW ■ TRASTUZUMAB-pkrb[a] BBW ■ TRASTUZUMAB-anns[a] BBW ■ TRASTUZUMAB-qyyp[a] BBW

(traz-**TOO**-zah-mab)
Herceptin, Ogivri[a]**, Ontruzant**[a]**, Herzuma**[a]**, Kanjinti**[a]**, Trazimera**[a]
Monoclonal antibody
Antineoplastic
pH 6

USUAL DOSE

Trastuzumab-dkst (Ogivri)[a]**, trastuzumab-pkrb (Herzuma)**[a]**, trastuzumab-dttb (Ontruzant)**[a]**, trastuzumab-anns (Kanjinti)**[a]**, and trastuzumab-qyyp (Trazimera)**[a] **are biosimilar drugs of trastuzumab (Herceptin). Unless specifically stated otherwise, monograph information and the use of the name *trastuzumab*** or *trastuzumab product(s)* applies to all six formulations.

DO NOT substitute trastuzumab products for or with ado-trastuzumab emtansine.

Pretreatment:

Verify pregnancy status. Preassessment required to determine appropriate patient selection, and baseline studies indicated; see Precautions and Monitor.

Premedication:

Pretreatment with antihistamines (e.g., diphenhydramine) and/or corticosteroids (e.g., dexamethasone) may be indicated and is suggested for patients being retreated after a hypersensitivity reaction or a severe infusion reaction; see Precautions. Pretreatment may not be successful; hypersensitivity reaction and/or infusion reaction may recur. Combination therapies may require additional premedication; refer to product monographs.

Adjuvant treatment of breast cancer:

Administer according to one of the following dose regimens and schedules for a total of

52 weeks of trastuzumab therapy (extending adjuvant treatment beyond 1 year is not recommended):

1. ***During and following paclitaxel, docetaxel, or docetaxel/carboplatin:*** Administer an initial dose of ***trastuzumab*** 4 mg/kg as an infusion over 90 minutes. Follow with a dose of 2 mg/kg as an infusion over 30 minutes at weekly intervals for the first 12 weeks when given in combination with ***paclitaxel or docetaxel*** or for 18 weeks when given in combination with ***docetaxel/carboplatin.*** Beginning 1 week after the last 2-mg/kg weekly dose of ***trastuzumab,*** administer ***trastuzumab*** 6 mg/kg as an infusion over 30 to 90 minutes every 3 weeks.
2. ***As a single agent within 3 weeks of completion of multimodality, anthracycline-based chemotherapy regimens,*** administer an initial dose of ***trastuzumab*** 8 mg/kg as an infusion over 90 minutes. Follow with a dose of 6 mg/kg as an infusion over 30 to 90 minutes every 3 weeks.
3. See clinical studies in prescribing information for different treatment regimens used. In all studies, ***trastuzumab*** was initiated ***after completion of the doxorubicin and cyclophosphamide treatment cycles.***

Metastatic breast cancer:

Initial dose:

4 mg/kg as an infusion over 90 minutes. Follow with a ***maintenance dose*** of 2 mg/kg as an infusion over 30 minutes at weekly intervals. Trastuzumab is administered until tumor progression.

Metastatic breast cancer in combination therapy with paclitaxel:

Trastuzumab dose as above. ***Paclitaxel dose:*** 175 mg/M^2 over 3 hours every 21 days for at least 6 cycles. See paclitaxel monograph.

Metastatic gastric cancer in combination with cisplatin and capecitabine or 5-fluorouracil:

Initial dose:

8 mg/kg as an infusion over 90 minutes. Follow with a dose of 6 mg/kg as an infusion over 30 to 90 minutes every 3 weeks until disease progression. See individual monographs and/or prescribing information and specific protocol for doses of cisplatin and capecitabine or 5-fluorouracil.

DOSE ADJUSTMENTS

Withhold trastuzumab dose for at least 4 weeks for either (1) equal to or greater than a 16% absolute decrease in left ventricular ejection fraction (LVEF) from baseline assessment, or (2) LVEF below institutional limits of normal and equal to or greater than 10% absolute decrease in LVEF from baseline assessment.

May resume trastuzumab if within 4 to 8 weeks the LVEF returns to normal limits and the absolute decrease from baseline is equal to or less than 15%. Discontinue permanently for a persistent (more than 8 weeks) LVEF decline or for suspension of trastuzumab dosing on more than three occasions for cardiomyopathy. ■ See prescribing information for recommended actions if a dose is missed by either 1 week or less or by more than 1 week.

DILUTION

Check vial labels to ensure use of trastuzumab and **not** ado-trastuzumab emtansine.

420-mg multiple-dose vial (Herceptin, Ogivri, Herzuma, Kanjinti, and Trazimera):

Manufacturers with the exception of Kanjinti supply a vial of bacteriostatic water for injection (BWFI) for dilution. Confirm content of vial; 20 mL is required to obtain the correct concentration. Inject diluent slowly directed at the lyophilized cake. Swirl gently; ***do not shake***. Allow vial to stand for 5 minutes; slight foaming is permissible. Will yield a multidose solution containing 21 mg/mL. Label vial immediately with a "do not use after" date 28 days from date of reconstitution. SWFI may be used to reconstitute trastuzumab for patients with a known hypersensitivity to benzyl alcohol, but the calculated dose must be withdrawn, used immediately, and the balance of the reconstituted solution discarded. Reconstituted solution must be further diluted and given as an infusion. Withdraw the calculated dose from the reconstituted vial (21 mg/mL) and add it to an infusion bag containing 250 mL of NS. Gently invert to mix the solution.

150-mg single-dose vial (Herceptin, Herzuma, Ogivri, and Ontruzant):

Reconstitute each vial with 7.4 mL of SWFI (SWFI not supplied). Inject diluent slowly at the lyophilized cake. Swirl gently; ***do not shake***. Allow vial to stand for 5 minutes; slight foaming is permissible. Will yield a single-dose solution containing 21 mg/mL. Use immediately after reconstitution.

Filters:

In-line filters are not necessary but may be used (0.2-micron filters were evaluated with ***Herceptin***).

Storage:

Refrigerate unopened and reconstituted vials at 2° to 8° C (36° to 46° F). Vials reconstituted with supplied diluent are stable for 28 days after reconstitution. Discard remaining diluent. Discard reconstituted trastuzumab product after expiration date written or stamped on vial. Immediate use preferred if reconstituted with SWFI. However, it may be stored for up to 24 hours refrigerated at 2° to 8° C (36° to 46° F). Discard unused portion whether used immediately or refrigerated for up to 24 hours. Solutions diluted in NS, including those diluted in polyvinyl chloride or polyethylene bags, may be refrigerated for no more than 24 hours before use. This storage time is in addition to the time allowed for the reconstituted vials. Do not freeze reconstituted or diluted trastuzumab products. If needed, refrigerated and unopened 420 mg vials of Trazimera may be removed from the refrigerator and stored at RT up to 30° C (86° F) for a single period of up to 3 months in the original carton to protect from light. Once removed, do not return to the refrigerator, and discard after 3 months or by the expiration date stamped on the vial, whichever occurs first. Write the revised expiration date in the space provided on the carton labeling.

COMPATIBILITY

Manufacturer states, "Do not reconstitute with drugs other than BWFI or SWFI. Further dilute infusion with NS. ***Infusions should not be administered or mixed with dextrose solutions. Do not mix trastuzumab products with other drugs.***" Is **compatible** with polyethylene and polyvinylchloride infusion bags and tubing.

RATE OF ADMINISTRATION

For infusion only; do not administer as an IV push or bolus. Use of a microdrip (60 gtt/min) or other IV controller suggested. Decrease rate of infusion for mild or moderate infusion reactions.

Initial dose:

A single dose as an infusion over a minimum of 90 minutes. Observe for chills, fever, or other infusion-associated symptoms; see Precautions/Monitor.

Maintenance dose:

If the initial dose was well tolerated, administer a single dose as an infusion over 30 to 90 minutes (based on regimen; see Usual Dose).

ACTIONS

A recombinant DNA–derived humanized monoclonal antibody that selectively binds with high affinity to the extracellular domain of the human epidermal growth factor receptor 2 (HER2) protein. Inhibits proliferation and mediates an antibody-dependent cellular toxicity in cancer cells that overexpress the HER2 protein. Half-life increases and clearance decreases with increasing doses. May cross the placental barrier. May be secreted in breast milk.

INDICATIONS AND USES

Indicated for adjuvant treatment of breast cancer that is HER2-overexpressing, node-positive or node-negative (ER/PR-negative or with one high-risk feature). May be used as part of a treatment regimen that may consist of (1) doxorubicin (Adriamycin), cyclophosphamide (Cytoxan), and either paclitaxel (Taxol) or docetaxel (Taxotere); (2) part of a treatment regimen with docetaxel and carboplatin; or (3) a single agent following multimodal anthracycline-based therapy ***(Herceptin, Ogivri, and Ontruzant only)***. ■ As a single agent for treatment of patients with metastatic breast cancer whose tumors overexpress the HER2 protein and who have received one or more chemotherapy regimens for their metastatic disease. ■ In combination with paclitaxel (Taxol) for the first-line treatment of patients with metastatic breast cancer whose tumors overexpress the HER2 protein and who have not received chemotherapy for their metastatic disease. ■ In combination with cisplatin and capecitabine (Xeloda) or 5-fluorouracil (5-FU) for treatment of patients with HER2-overexpressing metastatic gastric or gastroesophageal junction adenocarcinoma who have not received prior treatment for metastatic disease ***(Herceptin, Ogivri, and Ontruzant only)***. ■ Select patients for therapy based on an FDA-approved companion diagnostic for trastuzumab.

CONTRAINDICATIONS

None known when used as indicated; see Precautions.

PRECAUTIONS

Do not administer as an IV push or bolus. ■ Trastuzumab should be used only in patients whose tumors have HER2 overexpression or HER2 gene amplification in tumor specimens. Tumor histology differs; use FDA-approved tests for specific tumor type (breast or gastric cancers) to assess HER2 overexpression and HER2 gene amplification. Must be performed in laboratories with demonstrated proficiency in the specific technology. ■ Administered by or under the direction of the physician specialist. May be given on an outpatient basis. ■ Adequate laboratory and supportive medical resources must be available. ■ Emergency equipment and drugs for treatment of left ventricular dysfunction and/or infusion reactions must be immediately available; see Antidote. ■ Use with caution in patients with known hypersensitivity to trastuzumab, Chinese hamster ovary cell proteins, benzyl alcohol, or any component of this product. ■ Serious and fatal infusion reactions and pulmonary toxicity have been reported. Retreatment after full recovery from an infusion reaction has been tried following pretreatment with antihistamines and/or corticosteroids. Some tolerated treatment; others had another severe reaction. ■ Can cause subclinical and clinical cardiac failure. Incidence of cardiac dysfunction was highest in patients who received trastuzumab with an anthracycline-containing chemotherapy regimen (e.g., doxorubicin [Adriamycin]) and in elderly patients; see Drug/Lab Interactions. ■ Can cause left ventricular cardiac dysfunction, arrhythmias, hypertension, disabling cardiac failure, cardiomyopathy, and cardiac death. May also cause asymptomatic decline in left ventricular ejection fraction (LVEF). ■ Use extreme caution in treating patients with pre-existing cardiac dysfunction or pulmonary compromise. Pre-existing cardiac disease or prior cardiotoxic therapy (e.g., anthracyclines), radiation therapy to the chest, or pre-existing pulmonary compromise secondary to intrinsic lung disease and/or malignant pulmonary involvement may decrease ability to tolerate trastuzumab. ■ May exacerbate chemotherapy-induced neutropenia.

Monitor:

Select patients based on HER2 protein overexpression or HER2 gene amplification in tumor specimens. Assessment of HER2 protein overexpression and HER2 gene amplification should be performed using FDA-approved tests specific for breast or gastric cancers. Improper assay performance can lead to unreliable results. ■ Obtain baseline CBC with differential and platelet count and repeat as needed. ■ Monitor all vital signs before and during therapy. ■ Treatment with trastuzumab can result in the development of ventricular dysfunction and CHF. Evaluate left ventricular function before and during treatment. For all treatment regimens (monotherapy and/or combination therapies), patients should have a thorough baseline cardiac assessment, including a history and physical exam and determination of LVEF by an echocardiogram or a MUGA scan. Monitoring and assessment may not identify all patients at risk for developing cardiotoxicity. ■ Monitor closely throughout treatment for S/S of deteriorating cardiac function (e.g., cough, dyspnea, paroxysmal nocturnal dyspnea, peripheral edema, S_3 gallop, or reduced ejection fraction [symptomatic or asymptomatic]). Suggested monitoring schedule includes a repeat evaluation of left ventricular function (echocardiogram or MUGA scan) every 3 months during treatment with trastuzumab and at least every 6 months for 2 years after completion of treatment if trastuzumab was used as a component of adjuvant therapy. More frequent monitoring should be used for patients with pre-existing cardiac dysfunction and/or if S/S of deteriorating cardiac function develop; see Dose Adjustments. ■ Onset and clinical course of infusion reactions are variable. Most occur during or immediately following the infusion or within 24 hours. Monitor patient until symptoms completely resolve. Chills and/or fever occur in 40% of patients during the first infusion. May be treated with acetaminophen, diphenhydramine, and meperidine with or without reduction in the rate of infusion. During infusion, monitor closely; asthenia, bronchospasm, dizziness, dyspnea, headache, hypotension (may be severe), hypoxia, nausea, pain (may be at tumor site), rash, rigors, and vomiting have also occurred. ■ Monitor closely; in addition to the symptoms of infusion reaction previously noted, severe and sometimes fatal hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, hypotension, urticaria) and pulmonary reactions (e.g., dyspnea, interstitial pneumonitis, pulmonary infiltrates, pleural effusions, noncardiogenic pulmonary edema, pulmonary fibrosis, pulmonary insufficiency, hypoxia, and ARDS) have occurred during and after the infusion. ■ Monitor for thrombocytopenia (platelet count less than $50,000/mm^3$). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Not a vesicant; if extravasation occurs, discontinue infusion and restart using another vein.

Patient Education:

During infusion, promptly report chills and/or fever and other S/S of infusion reaction. ■ Promptly report cough, difficulty breathing, weight gain, and swelling of extremities. ■ Avoid pregnancy; use effective contraception during treatment and for at least 7 months after the last dose of trastuzumab. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy. Verify pregnancy status of females of reproductive potential before initiating trastuzumab. Can cause fetal harm. Increases the risk for oligohydramnios and oligohydramnios sequence manifesting as pulmonary hypoplasia, skeletal abnormalities, and neonatal death. Pregnant women who receive ***Herceptin*** are encouraged to enroll in the MotHER Pregnancy Registry and to report the trastuzumab exposure to the manufacturer (Genentech). ■ There is no information on the presence of trastuzumab in human milk, the effects on the breast-fed infant, or the effects on milk production. Consider the developmental and health benefits of breast-feeding along with the mother's clinical need for trastuzumab treatment and any potential adverse effects on the breast-fed child from trastuzumab or from the underlying maternal condition. This consideration should also take into account the trastuzumab washout period of 7 months. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Advanced age may increase the risk of cardiac dysfunction.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been done. Use with **paclitaxel** may decrease trastuzumab clearance and increase serum levels. Paclitaxel concentration is not affected. ■ The plasma concentration of capecitabine, carboplatin, cisplatin, docetaxel, doxorubicin, and paclitaxel was not altered when used in combination with trastuzumab. ■ Risk of cardiotoxicity increased with concurrent use or previous use of **anthracyclines** (e.g., doxorubicin). Patients who receive anthracycline after stopping trastuzumab may also be at increased risk for cardiac dysfunction. If possible, physicians should avoid anthracycline-based therapy for up to 7 months after stopping trastuzumab. If anthracyclines are used, carefully monitor the patient's cardiac function. ■ Bone marrow toxicity may be additive with **other antineoplastic agents** (e.g., anthracyclines, cyclophosphamide).

SIDE EFFECTS

Cardiomyopathy, pulmonary toxicity, infusion reactions, and exacerbation of chemotherapy-induced neutropenia are the most serious side effects. Anemia, chills, cough, diarrhea, dysgeusia, dyspnea, fatigue, fever, headache, infections, infusion reactions, insomnia, mucosal inflammation, myalgia, nasopharyngitis, nausea, neutropenia, rash, stomatitis, thrombocytopenia, upper respiratory tract infections, vomiting, and weight loss are most common. Side effects that cause interruption or discontinuation of therapy include severe infusion reactions, pulmonary toxicity, congestive heart failure, and a decline in left ventricular cardiac function. Abdominal pain, accidental injury, acne, anorexia, arthralgia, asthenia, back pain, bone pain, depression, dizziness, edema, flu syndrome, headache, herpes simplex, hypersensitivity reactions, hypotension, neuropathy, pain (may be at tumor site), paresthesia, peripheral edema, peripheral neuritis, pharyngitis, rash, rhinitis, sinusitis, and tachycardia have been reported in more than 5% of patients. Many other serious side effects have been reported in some patients (e.g., cardiac arrest, coagulation disorder, death, hypersensitivity reactions [e.g., angioedema, bronchospasm, dyspnea, urticaria, wheezing], hypertension, hypotension, noncardiogenic pulmonary edema, pancytopenia, pericardial or pleural effusion, pulmonary infiltrates, pulmonary insufficiency and hypoxemia requiring O_2 and/or ventilatory support, shock arrhythmia, syncope, vascular thrombosis).

Post-Marketing:

Serious adverse events including hypersensitivity reactions and infusion reactions, including some with a fatal outcome; and pulmonary events including ARDS and death. Symptoms occurred most commonly during the infusion, but some occurred 24 hours or more after the infusion. Renal toxicity (glomerulopathy) and immune thrombocytopenia have also been reported. Cases of possible tumor lysis syndrome have been reported. Cases of oligohydramnios and oligohydramnios sequence manifesting as pulmonary hypoplasia, skeletal abnormalities, and neonatal death have been reported when trastuzumab has been administered to pregnant women.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Decrease rate of infusion for mild or moderate infusion reactions. Interrupt infusion if dyspnea or clinically significant hypotension occurs. Discontinue trastuzumab for severe or life-threatening infusion reactions. Discontinue infusion in patients who develop anaphylaxis, angioedema, ARDS, and interstitial pneumonitis. Discontinue trastuzumab in patients receiving adjuvant therapy, and withhold therapy in patients with metastatic disease for clinically significant decrease in left ventricular function; see Dose Adjustments. Safety of continuation or resumption of therapy has not been studied. Treatment may include diuretics, ACE inhibitors, inotropic agents, beta-blockers, and/or supplemental oxygen. Infusion reaction is treated with acetaminophen, diphenhydramine, and meperidine. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity from concurrent antineoplastics. Treat hypersensitivity reactions (may be more frequent with coadministration of paclitaxel) with epinephrine, antihistamines, corticosteroids, bronchodilators, and oxygen. To treat extravasation, apply cold compresses and elevate extremity. Resuscitate as indicated.

TREPROSTINIL

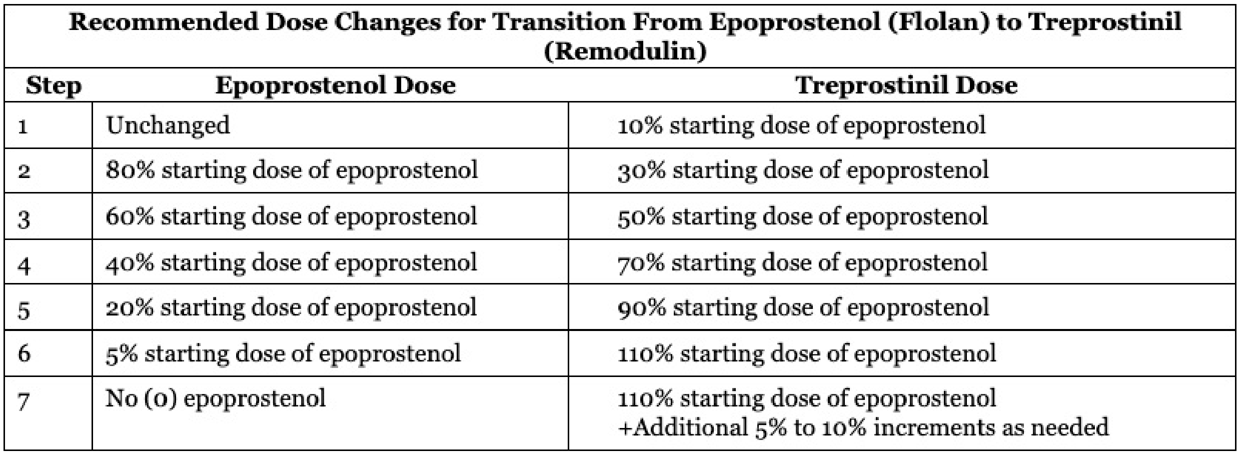
(treh-**PROS**-tin-il)
Remodulin
Prostacyclin; Prostaglandin
Vasodilator
pH 6 to 7.2

USUAL DOSE

Preferred route of administration is SC; see prescribing information for SC administration. IV route indicated if the SC route is not tolerated. Dosing by the SC route (undiluted) and by the IV route (must be diluted) are considered bioequivalent at steady state at a dose of 10 ng/kg/min. Administered IV by continuous infusion via a surgically placed indwelling central venous catheter, using an infusion pump designed for IV drug delivery. See Monitor for infusion pump specifications. If clinically necessary, a peripheral IV, preferably placed in a large vein, may be used for temporary short-term administration of treprostinil. Risk of thrombophlebitis is increased if used for more than a few hours. The infusion rate is initiated at 1.25 ng/kg/min. Ideal body weight is used to calculate the dose. The goal of therapy is to establish a dose at which symptoms of pulmonary arterial hypertension (PAH) are improved while minimizing excessive systemic effects (e.g., anxiety, emesis, headache, infusion site pain or reaction, nausea, restlessness); see Dose Adjustments.

Transition from epoprostenol (Flolan) to treprostinil:

Accomplished by initiating the infusion of treprostinil and increasing it, while simultaneously reducing the dose of IV epoprostenol. Transition should take place in the hospital with constant observation of response (e.g., walk distance and S/S of disease progression). Dose is individually titrated to a dose that allows transition while balancing prostacyclin-limiting side effects (e.g., anxiety, diarrhea, dizziness, edema, flushing, headache, hypotension, jaw pain, nausea, restlessness, syncope). During the transition treat symptoms of PAH with increases in the dose of treprostinil (Remodulin); treat side effects associated with prostacyclin and prostacyclin analogs by decreasing the dose of epoprostenol (Flolan). Recommended starting dose of treprostinil is 10% of the current epoprostenol dose. The treprostinil dose is then increased gradually as the epoprostenol dose is decreased based on constant observation of response. See the following chart for recommended transition dose changes.



Recommended Dose Changes for Transition From Epoprostenol (Flolan) to Treprostinil (Remodulin)

Step	Epoprostenol Dose	Treprostinil Dose
1	Unchanged	10% starting dose of epoprostenol
2	80% starting dose of epoprostenol	30% starting dose of epoprostenol
3	60% starting dose of epoprostenol	50% starting dose of epoprostenol
4	40% starting dose of epoprostenol	70% starting dose of epoprostenol
5	20% starting dose of epoprostenol	90% starting dose of epoprostenol
6	5% starting dose of epoprostenol	110% starting dose of epoprostenol
7	No (0) epoprostenol	110% starting dose of epoprostenol +Additional 5% to 10% increments as needed

DOSE ADJUSTMENTS

Goal of chronic dose adjustments is to establish a dose at which pulmonary hypertension (PAH) symptoms are improved while excessive pharmacologic effects of treprostinil (e.g., anxiety, emesis, headache, infusion site pain or reaction, nausea, restlessness) are minimized. ■ If the initial dose of 1.25 ng/kg/min cannot be tolerated because of systemic effects, the initial infusion rate should be reduced to 0.625 ng/kg/min. ■ Reduce the initial dose to 0.625 ng/kg/min of ideal body weight in patients with mild or moderate hepatic insufficiency, increase cautiously, and monitor closely. Has not been studied in patients with severe hepatic insufficiency. ■ Depending on clinical response, the infusion rate may be increased in increments of no more than 1.25 ng/kg/min per week for the first 4 weeks, and then no more than 2.5 ng/kg/min per week for the remaining duration of therapy. Dose may be adjusted more often if tolerated. ■ Dose should be increased for a lack of improvement in or worsening of symptoms, and it should be decreased for excessive systemic effects or unacceptable infusion site symptoms. ■ Avoid abrupt cessation of infusion; see Precautions. ■

Restarting a treprostinil infusion within a few hours after an interruption can be done using the same dose rate. Interruptions for longer periods may require the dose of treprostinil to be retitrated. ■ Dosing should be cautious if used in the elderly; see Elderly. ■ Dose adjustment may be necessary if inhibitors or inducers of CYP2C8 are added or withdrawn; see Drug/Lab Interactions.

DILUTION

Available in several concentrations. May be administered as supplied for SC administration. Must be diluted for IV infusion with either SW, NS, or sterile diluent for Flolan or sterile diluent for epoprostenol sodium. When used along with catheter care guidelines, the use of a high-pH glycine diluent such as sterile diluent for Flolan or sterile diluent for epoprostenol sodium has been associated with a lower incidence of bloodstream infections compared with neutral diluents (SWFI, NS). The desired length of an infusion between changeovers is up to 48 hours, and reservoirs typically have volumes of 50 or 100 mL. With this information, select a predetermined infusion rate.

Dilution requires a two-step process.

Step 1: Calculate the required concentration of treprostinil with the following formula.

$$\begin{array}{c}\textbf{Diluted Intravenous}\\ \textbf{Treprostinil}\\ \textbf{Concentration}\\ \text{(mg/mL)}\end{array} = \frac{\begin{array}{c}\textbf{Dose}\\ \text{(ng/kg/min)}\end{array} \times \begin{array}{c}\textbf{Weight}\\ \text{(kg)}\end{array} \times \mathbf{0.00006}}{\begin{array}{c}\textbf{Intravenous Infusion Rate}\\ \text{(mL/hr)}\end{array}}$$

Step 2: Calculate the amount of treprostinil injection needed to make the required concentration for the given reservoir size with the following formula.

$$\begin{array}{c}\textbf{Volume of}\\ \textbf{Treprostinil}\\ \textbf{Injection}\\ \text{(mL)}\end{array} = \frac{\begin{array}{c}\textbf{Diluted Intravenous}\\ \textbf{Treprostinil Concentration}\\ \text{(mg/mL)}\end{array}}{\textbf{Treprostinil Vial Strength}\ \text{(mg/mL)}} \times \begin{array}{c}\textbf{Total Volume of Diluted}\\ \textbf{Treprostinil Solution}\\ \textbf{in Reservoir}\\ \text{(mL)}\end{array}$$

Add the calculated amount of treprostinil to the pump reservoir along with a sufficient volume of SW, NS, sterile diluent for Flolan, or sterile diluent for epoprostenol sodium to achieve the desired total volume in the reservoir. See prescribing information for examples at different doses.

Filters:

An in-line 0.22- or 0.2-micron pore size filter should be used.

Storage:

Stable until expiration date stored at CRT. Multiple-dose vials may be stored at CRT after initial opening but must be discarded 30 days after initial entry. Diluted solutions are stable at ambient temperatures when stored for up to 14 days using high-pH glycine diluent at concentrations as low as 0.004 mg/mL (4,000 ng/mL). See following chart for storage and administration limits based on diluent.

Selection of Diluent		
Diluent	**Storage Limits**	**Administration Limits**
None	See Storage	16 weeks at 40° C
Sterile diluents for remodulin, flolan, or epoprostenol	14 days at room temperature	48 hours at 40° C
Sterile water for injection, 0.9% sodium chloride for injection	4 hours at room temperature or 24 hours refrigerated	48 hours at 40° C

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist. Consider specific use and vehicle for administration. Use of a multilumen catheter should be considered if other IV therapy is used.

RATE OF ADMINISTRATION

Determined by required dose, concentration of treprostinil, and length of administration time desired for each prepared dose. See formulas in Dilution. Administered through an in-line 0.22- or 0.2-micron pore size filter.

ACTIONS

A prostacyclin vasodilator. Produces vasodilation and tachycardia. It directly vasodilates pulmonary and systemic arterial vascular beds and inhibits platelet aggregation. Right and left ventricle afterload is reduced, and cardiac output and stroke volume are increased. Has a dose-related negative inotropic (contracting) and lusitropic (relaxing) effect on the heart. No major effects on cardiac conduction have been observed. Has been shown to improve dyspnea and fatigue and S/S of PAH. Metabolized in the liver by CYP2C8. Half-life when given SC is approximately 4 hours. Primarily excreted in urine with a small amount as unchanged drug and a larger amount as metabolites. Some excretion in feces.

INDICATIONS AND USES

Treatment of pulmonary arterial hypertension (PAH) (WHO Group 1) to diminish symptoms associated with exercise. Effectiveness established in patients with NYHA Functional Class II to IV symptoms and etiologies of idiopathic or heritable PAH, PAH associated with congenital systemic-to-pulmonary shunts, or PAH associated with connective tissue diseases. Primary route of administration is as a continuous SC infusion. Indicated as an IV infusion via a central IV line for patients not able to tolerate a SC infusion (e.g., severe pain or reaction at injection site) and/or for patients in whom the risks associated with chronic indwelling central venous catheters (e.g., serious bloodstream infections) are considered warranted. ■ To diminish the rate of clinical deterioration in patients with pulmonary arterial hypertension requiring transition from epoprostenol (Flolan). Carefully consider the risks and benefits of each drug before transition.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For SC or IV use only. Continuous SC infusion (undiluted) is preferred. ■ Administered under the direction of a physician experienced in the diagnosis and treatment of PAH. Initiation of treprostinil should occur in a setting with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Use of a multilumen catheter should be considered if other IV therapy is indicated. ■ For long-term therapy, the patient or a specific caregiver must be capable of administering treprostinil and caring for the infusion system and implanted central venous catheter. ■ Central venous catheter route has been associated with the risk of bloodstream infections and sepsis, which may be fatal. Therefore continuous SC infusion is preferred. Administration of IV treprostinil with a high pH glycine diluent has been associated with a lower incidence of bloodstream infections when compared with neutral diluents; see Dilution. ■ Avoid abrupt withdrawal or sudden large reductions in dose; may result in worsening of PAH symptoms. ■ Has not been studied in patients with severely impaired hepatic function. ■ Titrate slowly and monitor closely in patients with hepatic or renal insufficiency; exposure to greater systemic concentrations is more likely relative to patients with normal hepatic or renal function. ■ Treprostinil is both a pulmonary and a systemic vasodilator. In patients with low systemic arterial pressure, treatment with treprostinil may cause symptomatic hypotension. ■ Treprostinil inhibits platelet aggregation and increases the risk of bleeding. ■ See Monitor, Patient Education, and Drug/Lab Interactions.

Monitor:

The ambulatory infusion pump should be small and lightweight; have occlusion/no delivery, low battery, programming error, and motor malfunction alarms; have delivery accuracy of ±6% or better of the hourly dose; and be positive-pressure driven. The reservoir should be made of polyvinyl chloride, polypropylene, or glass. ■ The patient must have immediate access to a backup infusion pump and infusion sets to avoid potential interruptions in drug delivery. ■ Confirm patient’s or caregiver’s ability to aseptically and correctly prepare and administer treprostinil and provide indwelling catheter care. ■ Observe for dose-limiting side effects. ■ Monitor for symptomatic hypotension. ■ Monitor for any S/S of bleeding. ■ Thorough patient teaching and continued support services are imperative to facilitate a good clinical outcome. ■ See Precautions, Patient Education, and Drug/Lab Interactions.

Patient Education:

Therapy may continue for months or years. After initial dose titration and training, this is a self-administered drug. Patient and/or caregiver must assume responsibility for drug reconstitution, drug administration, and care of the permanent central venous catheter. ■ Aseptic technique during reconstitution and with routine care of permanent indwelling central venous catheter is imperative to prevent infection. ■ Promptly report fever or signs of infection at catheter site (e.g., redness, warmth). ■ Delivery of medication cannot be interrupted; will cause a rapid return of PAH symptoms. ■ Should have access to a backup infusion pump and IV infusion sets to avoid potential interruption in drug delivery. ■ Dose adjustments should be made only under the direction of the physician. ■ Promptly report expected side effects that may require a dose reduction (e.g., anxiety, emesis, headache, nausea, restlessness).

Maternal/Child:

Use during pregnancy only if clearly needed. PAH is associated with an increased risk of maternal and fetal mortality. Consider risk versus benefit. ■ Safety for use during labor and delivery not established. ■ Not known if treprostinil is secreted in human milk; use caution if required during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Insufficient numbers of patients 16 years of age or younger have been studied.

Elderly:

Dose selection in the elderly should be cautious. Consider increased potential for impaired organ function and concomitant disease or drug therapy. ■ Studies did not include sufficient numbers of patients over 65 years of age to assess their response as compared to younger patients.

DRUG/LAB INTERACTIONS

Interaction studies conducted with SC and oral formulations of treprostinil. ■ Hypotensive effects may be increased by **other drugs that have hypotensive effects** (e.g., diuretics [e.g., furosemide (Lasix)], antihypertensive agents [e.g., labetalol, nitroprusside], or vasodilators [e.g., hydralazine]). ■ Inhibits platelet aggregation; risk of bleeding may be increased with **anticoagulants** (e.g., warfarin [Coumadin]). ■ Coadministration of treprostinil and **P_{450} CYP2C8 enzyme inhibitors** (e.g., gemfibrozil [Lopid]) may increase exposure to treprostinil and increase side effects. ■ Coadministration of treprostinil and **P_{450}CYP2C8 enzyme inducers** (e.g., rifampin [Rifadin]) may decrease exposure to treprostinil and decrease its effectiveness. ■ Does not inhibit selected cytochrome P_{450} isoenzymes (e.g., CYP1A2, CYP2A6, CYP2C8, CYP2C9, CYP2C19, CYP2D6, CYP2E1, and CYP3A). Does not induce CYP1A2, CYP2B6, CYP2C9, CYP2C19, and CYP3A. ■ Does not alter the pharmacokinetics of warfarin. Changes in the INR are not expected with coadministration. ■ Has been used concurrently with acetaminophen 4 Gm/day, esomeprazole, warfarin 25 mg/day, and fluconazole (Diflucan) 200 mg/day in healthy volunteers without adverse pharmacokinetic effects on treprostinil. Oral bosentan (Tracleer) and sildenafil (Revatio, Viagra) have been used concurrently with oral treprostinil; no pharmacokinetic interactions were observed.

SIDE EFFECTS

Diarrhea, edema, headache, hypotension, infusion site pain or reaction, jaw pain, nausea, and vasodilation are most common. Anxiety, flushing, IV line infections or sepsis, rash, restlessness, tachycardia, and vasodilation have also occurred with both usual doses and overdoses. Other side effects may relate to underlying disease (e.g., chest pain, dyspnea, fainting, fatigue, hypotension, pallor, right ventricular heart failure, vomiting).

Post-Marketing:

Arthralgia, bone pain, cellulitis, dizziness, generalized rashes (macular or papular in nature), myalgia/muscle spasm, pain in extremity, pruritus, thrombophlebitis (with peripheral IV infusion), and thrombocytopenia.

Overdose:

Blurred vision; confusion; diarrhea; dizziness; flushing, including a feeling of warmth and redness of the face, neck, arms, and upper chest; headache; hypotension; light-headedness when getting up from a lying or sitting position; nausea and vomiting; sudden sweating; or unusual tiredness or weakness may be signs of overdose.

ANTIDOTE

Continuous maintenance of drug flow is imperative. Keep physician informed of all side effects. Most will be treated with dose reduction; some may require symptomatic treatment. Avoid abrupt withdrawal or sudden large reductions in dose; may result in worsening PAH symptoms. During the transition from epoprostenol (Flolan) to treprostinil (Remodulin), treat symptoms of PAH with increases in the dose of treprostinil (Remodulin); treat side effects associated with prostacyclin (e.g., anxiety, diarrhea, dizziness, edema, flushing, headache, hypotension, jaw pain, nausea, restlessness, syncope) by decreasing the dose of epoprostenol (Flolan). Treat symptoms of overdose promptly. Treprostinil is not removed by hemodialysis.

TRILACICLIB

(**TRY**-la-**SYE**-klib)
Cosela
Antineoplastic
Cyclin-dependent kinase inhibitor

USUAL DOSE

240 mg/M^2/dose IV. Given prior to a platinum/etoposide or topotecan-based chemotherapy; should be completed within 4 hours before the start of chemotherapy.

PEDIATRIC DOSE

Safety and efficacy have not been established.

DOSE ADJUSTMENTS

Renal:

No dosage adjustments provided by manufacturer.

Hepatic:

Do not use in moderate or severe impairment (total bilirubin >1.5 times the ULN). See prescribing information for dose modifications based on side effects.

DILUTION

Reconstitute each vial with 19.5 mL of D5W or NS to a concentration of 15 mg/mL. Swirl the vial gently for up to 3 minutes until completely dissolved; ***do not shake***. Reconstituted solution should be yellow or clear; do not use if solution is cloudy, discolored, or contains particulates. Withdraw appropriate dose volume and dilute in infusion bag of NS or D5W. Final concentration of diluted solution should be 0.5 to 3 mg/mL. Invert infusion bag gently; ***do not shake***.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than NS or D5W.

RATE OF ADMINISTRATION

Administer as an IV infusion over 30 minutes and complete infusion within 4 hours before start of chemotherapy. Flush the infusion line with at least 20 mL of D5W or NS after completing infusion. Give with an infusion set that has an in-line 0.2- or 0.22-micron filter.

ACTIONS

Selective and reversible cyclin-dependent kinase 4 and 6 inhibitor (CDK4/6). Through this inhibition, it prevents cells from proliferating in the presence of chemotherapy, thus leading to myelopreservation.

INDICATIONS AND USES

Chemotherapy-induced myelosuppression.

CONTRAINDICATIONS

Hypersensitivity (anaphylaxis) to trilaciclib or any component of the formulation.

PRECAUTIONS

Infusion-related reactions:

Infusion-site reactions, including thrombophlebitis and phlebitis, have been reported.

Pulmonary toxicity:

Severe, life-threatening, or fatal interstitial lung disease/pneumonitis have been reported.

Hypersensitivity:

Acute hypersensitivity reactions, including anaphylaxis, facial edema, and urticaria, have been reported.

Monitor:

Monitor for S/S of infusion site reactions, thrombophlebitis, phlebitis, and signs of acute drug hypersensitivity reactions (edema of face, eye, tongue; urticaria; pruritus; anaphylaxis) and pulmonary symptoms.

Patient Education:

Advise patients to call physician if they experience headache, stomachache, or weakness that gets worse. Educate patients on signs of hypersensitivity reactions (rash; hives; red, blistered, swollen skin; chest tightness; wheezing; trouble breathing or swallowing; hoarseness; swelling of face, lips, mouth, tongue, or throat).

Maternal/Child:

Check pregnancy status prior to use. Advise patient to use effective contraception during therapy and for at least 3 weeks after last dose. May cause fetal harm. Breast-feeding is not recommended.

Elderly:

See Usual Dose and Precautions.

DRUG/LAB INTERACTIONS

Cisplatin, dalfampridine, dofetilide, metformin.

SIDE EFFECTS

Fatigue, headache, hyperglycemia, hypocalcemia, hypokalemia, hypophosphatemia, increased AST, infusion-related reaction, injection site reaction, peripheral edema, skin rash, thrombosis.

ANTIDOTE

Discontinue infusion and treat appropriately for severe hypersensitivity reactions.

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Precautions and Monitor.

Adults and pediatric patients 10 years of age or older:

For all indications optimal clinical response is usually achieved with doses less than 60 mg/kg/24 hr. Usual therapeutic range of plasma levels is 50 to 100 mcg/mL. A total daily dose exceeding 250 mg should be given in divided doses. Oral and IV doses are considered to be equivalent and should be given at previously established intervals (e.g., every 6 or 8 hours). However, the equivalence shown between the IV and oral formulations at steady state was evaluated only in an every-6-hour regimen. If the IV formulation is given two or three times a day, close monitoring of trough plasma levels may be needed. See Precautions, Monitor, and Drug/Lab Interactions. Use of IV formulation for more than 14 days has not been studied. Transfer to oral dosing as soon as practical.

Complex partial seizures (monotherapy [initial]):

Begin with an initial dose of 10 to 15 mg/kg/24 hr. May be increased by 5 to 10 mg/kg/week until desired clinical response achieved or until side effects are dose limiting.

Complex partial seizures (conversion to monotherapy):

Begin with an initial dose of 10 to 15 mg/kg/24 hr. May be increased by 5 to 10 mg/kg/week until desired clinical response achieved or until side effects are dose limiting. Concomitant antiepilepsy drug (AED) dosage can usually be reduced by 25% every 2 weeks. Dose of AEDs may be decreased at the beginning of valproate therapy or decrease may be delayed for 1 to 2 weeks to avoid unwanted seizures.

Complex partial seizures (adjunctive therapy):

Begin with an initial dose of 10 to 15 mg/kg/24 hr. May be increased by 5 to 10 mg/kg/week until desired clinical response achieved. Has been used in combination with either carbamazepine or phenytoin. Dose adjustment of these drugs is not usually needed; however, drug interactions may occur; monitor plasma concentrations, especially during early therapy.

Simple and complex absence seizures:

Begin with an initial dose of 15 mg/kg/24 hr. May be increased by 5 to 10 mg/kg/week until seizures are controlled or side effects are dose limiting.

PEDIATRIC DOSE

No IV dose recommendations are available from the manufacturer for pediatric patients under 10 years of age. See Maternal/Child.

DOSE ADJUSTMENTS

Monitor plasma concentrations when transferring from oral to IV or IV to oral; dose increases or decreases may be indicated. ■ Reduce initial dose in the elderly; base subsequent doses on clinical response and/or development of side effects. ■ Reduced dose or discontinuation of therapy may be indicated if there is evidence of decreased food or fluid intake or excessive somnolence in the elderly. ■ Reduced dose or discontinuation of therapy may be indicated if there is evidence of bruising, hemorrhage, or a disorder of hemostasis/coagulation. ■ No dose adjustments required for impaired renal function, gender, or race. ■ See Maternal/Child and Drug/Lab Interactions.

DILUTION

Available as a clear, colorless solution in a 500 mg/5 mL single-dose vial. Each single dose should be diluted with at least 50 mL of D5W, NS, or LR.

Storage:

Store vials at CRT. Diluted solutions stable at CRT for 24 hours. No preservative added; discard unused contents of vial.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion over 60 minutes. Manufacturer has recommended that a rate of 20 mg/min not be exceeded; however, results of a single study suggest that selected patients tolerated rates from 1.5 to 3 mg/kg/min, allowing administration of up to 15 mg/kg/dose over 5 to 10 minutes. Incidence of side effects may be increased with too-rapid infusion.

ACTIONS

An anticonvulsant. A sodium salt of valproic acid. Therapeutic effect in epilepsy may result from increased brain concentrations of gamma-aminobutyric acid (GABA). Peak effect occurs at the end of a 60-minute infusion or 4 hours after an oral dose. Plasma protein binding is high and is concentration dependent. Concentration in CSF is similar to unbound concentrations in plasma (10%). Half-life range is 13 to 19 hours. The half-life will be in the lower part of the range in patients receiving other enzyme-inducing antiepileptic agents (e.g., carbamazepine, phenobarbital, phenytoin). Metabolized in the liver. 30% to 50% excreted in changed form in urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Use of IV product indicated in the following specific conditions when oral administration of valproate products (e.g., divalproex sodium) is temporarily not feasible. ■ Treatment of complex partial seizures occurring in isolation or with other seizures (monotherapy or adjunctive therapy). ■ Treatment of simple and complex absence seizures (monotherapy or adjunctive therapy). ■ Adjunctive treatment of multiple seizure types that include absence seizures.

Unlabeled uses:

Used alone or in combination with other antiepileptic drugs for treatment of patients with status epilepticus (refractory) who have not responded to other therapies.

Limitation of use:

Because of the risk to the fetus of decreased IQ, neural tube defects, and other major congenital malformations, which may occur very early in pregnancy, valproate products should not be used to treat women with epilepsy or bipolar disorder who are pregnant or who plan to become pregnant unless other medications have failed to provide adequate symptom control or are otherwise unacceptable. Valproate should not be administered to a woman of childbearing potential unless other medications have failed to provide adequate symptom control or are otherwise unacceptable.

CONTRAINDICATIONS

Known hypersensitivity to valproate products. ■ Patients with hepatic disease or significant hepatic dysfunction. ■ Patients known to have mitochondrial disorders caused by mutations in mitochondrial DNA polymerase γ (POLG) gene (e.g., Alpers-Huttenlocher syndrome), and pediatric patients under 2 years of age who are suspected of having a POLG-related disorder. ■ Patients with known urea cycle disorders. ■ Prophylaxis of migraine headaches in pregnant women and in women of childbearing potential who are not using effective contraception.

PRECAUTIONS

Use of IV valproate for more than 14 days has not been studied. ■ Safety of doses above 60 mg/kg/day is not known. ■ Has caused fatal hepatic failure. Incidents usually occur during the first 6 months of treatment. Patients with a history of hepatic disease, patients taking multiple anticonvulsants, pediatric patients, patients with congenital metabolic disorders, patients with severe seizure disorders accompanied by cognitive impairment, and patients with organic brain disease may be at particular risk. Pediatric patients under 2 years of age are at the greatest risk. If valproate is used in pediatric patients under 2 years of age with or without these increased risk factors, benefits must outweigh risks; use only as a sole agent and with extreme caution. Incidence of fatal hepatotoxicity decreases in progressively older patient groups. ■ Cases of life-threatening pancreatitis have been reported in both pediatric patients and adults receiving valproate. Some of the cases have been described as hemorrhagic with rapid progression from initial symptoms to death. May occur at any time from shortly after initiation of therapy to years later. If pancreatitis is diagnosed, valproate should be discontinued. ■ Patients with hereditary neurometabolic syndromes caused by DNA mutations of the mitochondrial DNA polymerase γ (POLG) gene (e.g., Alpers-Huttenlocher syndrome) have an increased risk of valproate-induced liver failure and death; see Contraindications and Monitor. ■ Hyperammonemic encephalopathy, sometimes fatal, has been reported in patients with urea cycle disorders (UCD). Before starting valproate, consider a possible diagnosis of UCD in patients with a history of unexplained encephalopathy or coma, encephalopathy associated with a protein load, pregnancy-related or postpartum encephalopathy, unexplained cognitive impairment, a history of elevated plasma ammonia or glutamine, cyclical vomiting or lethargy, episodic extreme irritability, ataxia, low BUN, protein avoidance, a family history of UCD or unexplained infant deaths, or any other S/S of UCD. ■ Hyperammonemia may be present even with normal liver function tests. Hyperammonemic encephalopathy should be considered in patients who present with lethargy and vomiting or altered mental status. Hyperammonemia should also be considered in patients who present with hypothermia (unintentional drop in body temperature to less than 35° C [95° F]). Elevation of ammonia may also be asymptomatic. ■ Hyperammonemia with or without encephalopathy has been reported with concomitant administration of valproic acid and topiramate (Topamax). Has occurred in patients who have tolerated either drug alone. S/S in most cases abated with discontinuation of either drug. ■ Hypothermia has occurred with valproate therapy both in conjunction with and in the absence of hyperammonemia. Can also occur in patients using concomitant topiramate with valproate after starting topiramate therapy or after increasing the dose of topiramate. ■ Hypothermia may be manifested by a variety of clinical abnormalities, including lethargy, confusion, coma, and significant alterations in other major organ systems such as the cardiovascular and respiratory systems. ■ Antiepileptic drugs (AEDs) increase the risk of suicidal thoughts or behavior in patients taking these drugs for any indication. Patients treated with any AED for any indication should be monitored for the emergence or worsening of depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior. Some behavioral changes resolved without intervention. Others required dose reduction or discontinuation of valproate. ■ The frequency of adverse events (particularly elevated liver enzymes and thrombocytopenia) may be dose-related. The benefit of improved therapeutic effect with higher doses should be weighed against the possibility of a greater incidence of adverse reactions. ■ Incidence of thrombocytopenia increases at total trough concentrations greater than 110 mcg/mL in females and greater than 135 mcg/mL in males. ■ Valproate use has also been associated with decreases in other cell lines and myelodysplasia. ■ Drug reaction with eosinophilia and systemic symptoms (DRESS), also known as multiorgan hypersensitivity, has been reported in patients receiving valproate therapy. May be fatal or life threatening. Initial S/S include fever, rash, and/or lymphadenopathy associated with other organ system involvement (e.g., arthralgia, hematologic abnormalities, hepatitis, myocarditis, myositis, nephritis). Eosinophilia is often present. Discontinue valproate and use alternative therapy. ■ Plasma protein binding is decreased and free fraction is increased in the elderly, in hyperlipidemic patients, in chronic hepatic disease, in impaired renal function, and in the presence of other drugs; see Drug/Lab Interactions. Total plasma concentrations may be normal, but free concentrations may be substantially elevated in these patients. ■ Antiepilepsy drugs should not be abruptly discontinued in patients being treated for major seizure activity. Reduce AED doses gradually to prevent status epilepticus. ■ Can cause major congenital malformations, particularly neural tube defects (e.g., spina bifida). In addition, valproate can cause decreased IQ scores and neurodevelopmental disorders after in utero exposure. Do not administer to a woman of childbearing potential unless other medications have failed to provide adequate symptom control or are otherwise unacceptable. In such situations, effective contraception should be used. Do not use to treat non–life-threatening conditions (e.g., migraine) or in women of childbearing age who are not using effective contraception. See Contraindications and Maternal/Child. ■ In vitro studies suggest that valproate may stimulate the replication of the HIV and CMV viruses under certain experimental conditions. The clinical significance of this is unknown but should be kept in mind when evaluating patients with HIV or CMV who are receiving valproate. ■ Not recommended for use in patients with acute head trauma for the prophylaxis of posttraumatic seizures.

Monitor:

Obtain baseline CBC with platelet counts and coagulation tests and monitor during therapy. Repeat before planned surgery and during pregnancy. Thrombocytopenia, inhibition of the secondary phase of platelet aggregation, and abnormal coagulation parameters (e.g., low fibrinogen, coagulation factor deficiencies, acquired von Willebrand disease) have been reported. ■ Obtain baseline serum liver testing and monitor frequently during therapy, especially during the first 6 months. ■ Observe closely for nonspecific symptoms that may precede serious or fatal hepatotoxicity (e.g., anorexia, facial edema, lethargy, loss of seizure control, malaise, weakness, vomiting). ■ Abdominal pain, anorexia, nausea, and vomiting may be symptoms of pancreatitis and should be evaluated promptly. ■ Valproate products should be used only after other anticonvulsants have failed in patients over 2 years of age who are clinically suspected of having a hereditary mitochondrial disease. Closely monitor during treatment for the development of acute liver injury with regular clinical assessments and serum liver testing. Perform POLG mutation testing and screening as indicated (e.g., family history, unexplained encephalopathy, refractory epilepsy [focal, myoclonic], status epilepticus at presentation, developmental delays, psychomotor regression, axonal sensorimotor neuropathy, myopathy cerebellar ataxia, ophthalmoplegia, or complicated migraine with occipital aura). ■ Therapeutic serum levels for most patients will range from 50 to 100 mcg/mL; however, a good correlation has not been established between daily dose, serum levels, and therapeutic effect. Some patients may be controlled with lower or higher serum concentrations. One contributing factor is the nonlinear, concentration-dependent protein binding of valproate, which affects the clearance of the drug. ■ Total serum valproic acid concentration is affected by variable free-fractions of drug; consider hepatic metabolism and protein binding when interpreting valproic acid concentrations. ■ Monitor antiepileptic concentrations more frequently whenever concomitant AEDs are being introduced or withdrawn, and observe closely for seizure activity. ■ Monitor serum concentrations more frequently if any of the risk factors listed in Dose Adjustments or Precautions are present, and when any drugs that affect hepatic enzymes are introduced or discontinued; see Drug/Lab Interactions. ■ When used as replacement therapy, the equivalence shown between the IV and oral formulations was evaluated only in an every-6-hour regimen. If valproate sodium is given two or three times daily, close monitoring of trough plasma levels may be needed to ensure therapeutic levels are being maintained. ■ Evaluate for S/S of UCD; see Precautions and Antidote. ■ Consider hyperammonemia encephalopathy in patients who develop unexplained lethargy and vomiting or changes in mental status. Consider hyperammonemia in patients who present with hypothermia. Elevations of ammonia may also be asymptomatic; monitor plasma ammonia levels closely; see Antidote. Treat hyperammonemia and assess for underlying UCD. ■ Observe patient closely for signs of CNS side effects; see Precautions. ■ Monitor for S/S of DRESS. ■ See Dose Adjustments, Precautions, and Drug/Lab Interactions for additional monitoring requirements.

Patient Education:

May cause drowsiness; determine effects before driving or operating any machinery. ■ Avoid pregnancy; use effective contraception; see Maternal/Child. ■ Read the patient information leaflet provided by manufacturer, and discuss your medical history and concurrent prescription and nonprescription medications with your health care provider. ■ Promptly report symptoms such as changes in mental state, fever, jaundice, lethargy, lymphadenopathy, rash, unexplained lethargy, unintentional drop in body temperature to less than 35° C (95° F); may be symptoms of serious side effects (e.g., hepatotoxicity, hyperammonemia, hypersensitivity) and require prompt evaluation and treatment. ■ Promptly report abdominal pain, anorexia, nausea, and/or vomiting. May indicate pancreatitis; medical evaluation may be required. ■ May increase the risk of suicidal thoughts and behavior. Promptly report emergence or worsening of the S/S of depression, any unusual changes in mood or behavior, or thoughts about self-harm. ■ There have been reports of male infertility coincident with valproate therapy. ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry. ■ See Maternal/Child.

Maternal/Child:

Valproate can cause fetal harm when administered to a pregnant woman. Avoid pregnancy; see Contraindications. Valproate should not be used to treat women with epilepsy or bipolar disorder who are pregnant or who plan to become pregnant unless other medications have failed to provide adequate symptom control or are otherwise unacceptable. There is an increased risk for major congenital malformations, particularly neural tube defects (e.g., spina bifida) and other birth defects such as craniofacial defects, cardiovascular malformation, hypospadias, and limb malformations. In addition, valproate can cause decreased IQ scores and neurodevelopmental disorders (including autism spectrum disorders) following in utero exposure. In utero exposure to valproate may also result in hearing impairment or hearing loss. The incidence of congenital malformations associated with the use of valproate by women with seizure disorders during pregnancy is higher than in women with seizure disorders who use other AEDs. The increased teratogenic risk from valproate in women with epilepsy is expected to be reflected in an increased risk in other indications (e.g., bipolar disorder, migraine). ■ Evidence suggests that folic acid supplementation before conception and during the first trimester decreases the risk for congenital neural tube defects in the general population. It is not known whether the risk of neural tube defects or decreased IQ in the offspring of women receiving valproate is reduced by folic acid supplementation. Dietary folic acid supplementation before conception and during pregnancy is recommended. Tests to detect neural tube and other defects should be considered as part of routine prenatal care in pregnant women receiving valproate. ■ To prevent major seizures, do not discontinue valproate abruptly in these patients; can precipitate status epilepticus, resulting in maternal and fetal hypoxia and a threat to life. ■ When used during pregnancy, valproate has caused hepatic failure or clotting abnormalities in the mother that may result in hemorrhagic complications in the neonate. Deaths have been reported. If clotting parameters are abnormal in the mother, then these parameters should also be monitored in the neonate; see Monitor. ■ Has caused hepatic failure in infants exposed to valproate in utero. ■ Has caused hypoglycemia in infants exposed to valproate in utero. ■ Use with caution during breast-feeding; is excreted in human milk. Monitor the breast-fed infant for signs of liver damage, including jaundice and unusual bruising or bleeding. ■ Neonates under 2 months of age have a markedly decreased ability to eliminate valproate compared with older pediatric patients and adults. ■ Pediatric patients 3 months to 10 years of age have 50% higher clearance rates based on weight compared to adults. ■ Younger pediatric patients, especially those receiving enzyme-inducing drugs (e.g., carbamazepine, phenobarbital, phenytoin) will require larger maintenance doses to achieve therapeutic valproic acid concentrations. ■ IV product has not been studied in pediatric patients under 2 years of age. If used, use as a sole agent with extreme caution. ■ Pediatric patients under 2 years of age are at an increased risk for developing fatal hepatotoxicity. ■ See Precautions and Monitor.

Elderly:

May be more prone to adverse events. Initial dose should be lower, and dosage should be increased slowly. Rate of clearance decreased, free fraction increased; see Dose Adjustments. ■ Monitor for fluid and nutritional intake, dehydration, somnolence, and other adverse events. Dose reduction or discontinuation of valproate should be considered in patients with decreased food or fluid intake and in patients with excessive somnolence. ■ A higher percentage of patients over 65 years of age reported accidental injury, infection, pain, somnolence, and tremor.

DRUG/LAB INTERACTIONS

Clearance increased and effectiveness reduced by **drugs that induce hepatic enzymes** (e.g., phenytoin, carbamazepine, phenobarbital, primidone, ritonavir); increased monitoring of valproate and concomitant drug concentrations indicated. ■ **Aspirin** decreases protein binding, inhibits metabolism, and increases free concentration of valproate; use caution and monitor valproate concentrations if administered concomitantly. ■ Peak concentrations increased if coadministered with **felbamate**; reduced dose of valproate indicated. ■ Metabolism may be decreased and serum levels increased when given concurrently with **erythromycin.** ■ **Carbapenem antibiotics** (e.g., ertapenem, meropenem) may reduce serum valproic acid concentrations to subtherapeutic levels, resulting in loss of seizure control. Monitor valproic acid levels. Consider alternative antibacterial or anticonvulsant therapy if serum valproate concentrations drop significantly or seizure control deteriorates. ■ **Estrogen-containing contraceptives** may increase the clearance of valproate, decreasing valproate concentration and potentially increasing seizure frequency; monitor serum valproate concentrations and clinical response when adding or discontinuing estrogen-containing products. ■ **Rifampin** may increase clearance of valproate and require dose adjustment. ■ Inhibits metabolism of **barbiturates** (e.g., phenobarbital) **and primidone,** increasing their effects. Monitor for neurologic toxicity; obtain barbiturate serum levels and reduce barbiturate dose as indicated. ■ May decrease serum levels of carbamazepine. **Carbamazepine** decreases plasma concentrations of valproate, and a loss of seizure control may occur; monitor carefully and increase valproate dose if indicated. ■ Concomitant use with **clonazepam** may induce absence status in patients with a history of absence-type seizures. ■ **Displaces some protein-bound drugs** (e.g., carbamazepine, diazepam, phenytoin, tolbutamide, warfarin). In addition to decreasing protein binding, may also decrease the metabolism of diazepam and phenytoin. Dose adjustments and serum concentrations may be indicated. ■ **Phenytoin** with valproate has caused breakthrough seizures in patients with epilepsy; adjust dose of phenytoin as indicated by serum concentrations. ■ Hyperammonemia with or without encephalopathy, as well as hypothermia, has been reported with concomitant administration of valproic acid and **topiramate**; see Precautions. ■ Monitor coagulation tests if administered with **anticoagulants** (e.g., warfarin). ■ CNS effects may be increased when given concurrently with **CNS depressants** (e.g., **benzodiazepines and tricyclic antidepressants**). ■ May decrease clearance and increase effects of **amitriptyline and nortriptyline**. Dose reduction of these drugs may be required. ■ Inhibits metabolism of **ethosuximide**; monitor serum concentrations of both drugs with concomitant administration. ■ Concurrent administration of **lamotrigine** and valproate may increase lamotrigine levels. Dose of lamotrigine should be reduced. ■ Serious skin reactions have been reported with concurrent use of **lamotrigine** and valproic acid. ■ Decreases clearance and may increase toxicity of **zidovudine**. ■ **Rufinamide** (Banzel) clearance is decreased by valproate. Concentrations were increased by less than 16% to 70% depending on the concentration of valproate. Patients stabilized on rufinamide before initiating valproate therapy should begin valproate at a low dose and titrate to a clinically effective dose. Similarly, patients on valproate should begin rufinamide at a dose lower than 10 mg/kg/day (pediatric patients) or 400 mg/day (adults). ■ Concomitant use with **propofol** may lead to increased blood levels of propofol. Reduce dose of propofol and monitor patients closely for signs of increased sedation or cardiorespiratory depression. ■ See package insert for additional information about many drugs that do not present significant clinical interactions. ■ May alter **thyroid function tests.** ■ May cause **false-positive urine ketone test.**

SIDE EFFECTS

Abdominal pain, alopecia, amblyopia/blurred vision, amnesia, anorexia with weight loss, asthenia, ataxia, bronchitis, constipation, depression, diarrhea, diplopia, dizziness, dyspepsia, dyspnea, ecchymosis, emotional lability, fever, flu syndrome, headache, increased appetite with weight gain, infection, insomnia, nausea, nervousness, nystagmus, peripheral edema, pharyngitis, rhinitis, somnolence, thinking abnormally, thrombocytopenia, tinnitus, tremor, and vomiting are most common. Accidental injury, back pain, chest pain, euphoria, hypesthesia, injection site inflammation, injection site pain, rash, sweating, taste perversion, and vasodilation were the next most commonly reported side effects. Psychiatric symptoms, including aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies, have also been reported. Frequency of elevated liver enzymes and thrombocytopenia may be dose related. Fatal hepatotoxicity (anorexia, facial edema, lethargy, loss of seizure control, malaise, sweating, vasodilation, vomiting, weakness) has occurred. See Precautions for other reported serious adverse events.

Overdose:

Somnolence, deep coma, heart block, and hypernatremia. Some fatalities have been reported.

Post-Marketing:

Many adverse reactions have been reported during post-approval use of valproate sodium. The frequency of reactions and/or causal relationship to valproate may be difficult to determine. Some of the reported reactions have included dermatologic reactions (e.g., erythema multiforme, nail and nail bed disorders, photosensitivity, Stevens-Johnson syndrome, toxic epidermal necrolysis), endocrine abnormalities (e.g., elevated testosterone, hirsutism, hyperandrogenism, secondary amenorrhea), enuresis, Fanconi's syndrome, hair color and texture changes, hematologic reactions (e.g., anemia including macrocytic with or without folate deficiency, aplastic anemia, bone marrow suppression), hypersensitivity reactions (including anaphylaxis), neurologic reactions (e.g., parkinsonism, acute or subacute cognitive decline and behavioral changes [apathy or irritability] with cerebral pseudoatrophy on imaging, acute or subacute encephalopathy in the absence of elevated ammonia levels, elevated valproate levels, or neuroimaging changes), osteopenia, osteoporosis, reproductive reactions (e.g., aspermia, azoospermia, male infertility), and weight gain.

ANTIDOTE

Keep physician informed of all side effects. Some may respond to a decrease in the rate of administration. Discontinue immediately if signs of suspected or apparent significant hepatic dysfunction appear (e.g., hyperammonemia, elevated liver function tests) or S/S of underlying UCD. Hepatic dysfunction may progress after valproate is discontinued. Discontinue if S/S of DRESS occur. Initiate alternate therapy. Reduce dose or discontinue if bruising, hemorrhage, or abnormal coagulation parameters occur (e.g., thrombocytopenia). Discontinue if S/S of pancreatitis occur. All of the above situations may be life threatening and will require immediate symptomatic treatment. Consideration should be given to discontinuing valproate in patients who develop hypothermia. Maintain a patent airway and resuscitate as indicated. Support patient as required in treatment of overdose; monitor and maintain adequate urine output. Hemodialysis is effective in overdose. Naloxone may reverse CNS depressant effects in overdose but may also reverse antiepilepsy effects of valproate. Psychotic symptoms may require dose reduction or discontinuation of valproate.

VACCINIA IMMUNE GLOBULIN INTRAVENOUS (HUMAN) BBW

(vack-**SIN**-ee-ah ih-**MUNE** **GLAW**-byoo-lin IV)
VIGIV
Immunizing agent (passive)

USUAL DOSE

Pretreatment:

Baseline studies may be indicated; see Monitor.

100 mg/kg (2 mL/kg) as a single-dose IV infusion; see Monitor. May be repeated based on the severity of symptoms and on individual patient response. Higher doses (200 mg/kg or 500 mg/kg) may be considered in patients who do not respond to the initial 100 mg/kg dose; see Precautions.

DOSE ADJUSTMENTS

Because of sucrose content, doses higher than 400 mg/kg are not recommended in patients with potential renal problems.

DILUTION

Contains sucrose; see Precautions. A ready-to-use liquid preparation supplied in a 50-mL vial containing 50 mg VIGIV/mL or 2,500 mg VIGIV/vial. Solution should be colorless, free of particulate matter, and not turbid. ***Do not shake vial; avoid foaming.*** Further dilution before or during administration is not recommended. Infusion should begin within 6 hours of entering the vial and be complete within 12 hours of entering the vial. Use of a dedicated IV line, a 0.22-micron in-line filter, and a constant infusion pump is recommended. If necessary, it may be piggybacked into a pre-existing IV line containing NS or D2½W, D5W, D10W, or D20W with or without NaCl added; see Compatibility. VIGIV should not be diluted more than 1:2 (v/v) with any of these solutions.

Filters:

Use of a 0.22-micron in-line filter is recommended; see Dilution.

Storage:

Store between 2° and 8° C (35.6° and 46.4° F). Do not use after expiration date. Infusion must begin within 6 hours and be complete within 12 hours of entering the vial. Discard partially used vials. Do not use if turbid or has been frozen.

COMPATIBILITY

Manufacturer states, "Administer separately from other drugs or medications." If necessary, it may be piggybacked into a pre-existing IV line containing NS or D2½W, D5W, D10W, or D20W with or without NaCl added. Flush line before and after administration. VIGIV should not be diluted more than 1:2 (v/v) with any of these solutions.

RATE OF ADMINISTRATION

Flush line before and after administration.

Administer 1 mL/kg/hr for the first 30 minutes. If no discomfort or adverse effects, it may be increased to 2 mL/kg/hr for the next 30 minutes and then to 3 mL/kg/hr for the remainder of the infusion, as tolerated. Infusion of 100 mg/kg (2 mL/kg) should take approximately 70 minutes in a 70-kg patient. Do not exceed these rates. Too-rapid infusion may cause infusion rate–related reactions (e.g., arthralgia, back pain, chills, fever, flushing, muscle cramps, nausea, vomiting, wheezing). ***In patients at risk for developing renal dysfunction, administer at the minimum concentration available and the minimum rate of infusion practicable.*** Use of a dedicated IV line, a 0.22-micron in-line filter, and a constant infusion pump (i.e., an IVAC pump or equivalent) is recommended.

ACTIONS

An immunoglobulin (Ig). Obtained from human plasma, purified, and standardized. Donors had received booster immunizations with the Dryvax smallpox vaccine. Specific methods (e.g., cold ethanol fractionation, detergents, nanofiltration, solvents) inactivate bloodborne viruses (e.g., hepatitis, HIV). Tested and found negative for antibodies against HIV, hepatitis, Creutzfeldt-Jakob disease, and others. Contains increased levels of protective antibodies against the vaccinia virus—the live virus used in the currently available smallpox vaccine. When use is necessary, can help to minimize possible risks associated with this highly effective smallpox vaccine. Half-life is approximately 22 days but may be decreased by fever or infection (increased catabolism or consumption).

INDICATIONS AND USES

Treatment and/or modification of the following conditions: aberrant infections induced by the vaccinia virus that include accidental implantation in the eyes (excluding isolated keratitis; see Contraindications), mouth, or other areas where vaccinia infection would be hazardous; eczema vaccinatum; progressive vaccinia; severe generalized vaccinia; and vaccinia infections in individuals who have skin conditions such as burns, impetigo, varicella-zoster, or poison ivy or in individuals who have eczematous skin lesions because of the activity or extensiveness of such lesions.

CONTRAINDICATIONS

Presence of isolated vaccinia keratitis. ■ Individuals known to have an allergic response to this or other human immunoglobulin preparations. ■ Contains trace amounts of IgA. Patients with isolated or selective IgA deficiency can develop antibodies to IgA and have an increased risk of anaphylactic reactions with subsequent exposure to blood products that contain IgA. ■ Not considered effective for the treatment of postvaccinal encephalitis.

PRECAUTIONS

For IV infusion only. ■ Hypersensitivity reactions are possible and have occurred with other IGIV preparations; administer in a facility with adequate equipment and supplies to monitor the patient and respond to any medical emergency. ■ Use extreme caution in individuals with a history of prior systemic hypersensitivity reactions. Incidence of anaphylaxis may be increased, especially with repeated injections. ■ Use caution when treating complications that include vaccinia keratitis; may cause increased corneal scarring. ■ IGIV products have been associated with renal dysfunction, acute renal failure, osmotic nephrosis, and death. Use extreme caution in patients with any degree of renal insufficiency; in patients 65 years of age and older; in patients with diabetes mellitus, paraproteinemia, sepsis, or volume depletion; and/or in patients receiving known nephrotoxic drugs. If used, should be administered at the minimum concentration available and at the minimum rate of infusion practicable. ***Products containing sucrose as a stabilizer have demonstrated an increased risk of renal dysfunction.*** Consider benefit versus risk before use. ■ May cause aseptic meningitis syndrome (AMS), which may begin from 2 hours to 2 days after treatment. Symptoms are drowsiness, fever, headache (severe), nausea and vomiting, nuchal rigidity, painful eye movements, and photophobia. Symptoms resolve if VIGIV is discontinued. A neurologic exam to rule out other causes of meningitis is indicated. ■ IGIV products have been associated with thrombotic events; use caution in patients with a history of cardiovascular disease or thrombotic episodes and in patients with thrombotic risk factors (e.g., cerebrovascular disease, coronary artery disease, diabetes, hypertension). Baseline assessment of blood viscosity should be made in patients at risk for hyperviscosity, including chylomicronemia, markedly high triglycerides, or monoclonal gammopathies. ■ Hemolysis and hemolytic anemia may develop. ■ Noncarcinogenic pulmonary edema (transfusion-related acute lung injury ([TRALI]) has been reported with other IGIV preparations; see Monitor. ■ Interacts with some glucose-monitoring systems; see Monitor and Drug/Lab Interactions.

Monitor:

Use of larger veins may reduce infusion site discomfort. ■ Correct volume depletion before administration. ■ Recording the lot number on vials is helpful. ■ Monitor vital signs and observe patient continuously during infusion. A precipitous drop in BP or anaphylaxis can occur at any time. Emergency equipment and supplies must be at bedside. ■ Monitor renal function (e.g., BUN, SCr) and urine output in patients at increased risk for renal failure. Obtain baseline studies, monitor at intervals, and discontinue future VIGIV therapy if renal function deteriorates. See Precautions. ■ Monitor for S/S of hemolysis (e.g., anemia, lysis of red blood cells, liberation of hemoglobin). ■ Monitor for S/S of TRALI (e.g., fever, hypoxemia, normal left ventricular function, pulmonary edema, severe respiratory distress). Usually occurs within 1 to 6 hours after completion of the transfusion. Manage with oxygen and adequate ventilatory support. If TRALI is suspected, test for the presence of antineutrophil antibodies in product and patient serum. ■ Some types of blood glucose testing systems (e.g., those based on the glucose dehydrogenase pyrroloquinoline quinone [GDH-PQQ] or glucose-dye-oxidoreductase methods) could falsely interpret the maltose contained in VIGIV as glucose. To avoid this interference by maltose contained in VIGIV, blood glucose measurements in patients receiving VIGIV must be done with a glucose-specific method (monitor and test strips); see Drug/Lab Interactions.

Patient Education:

Report a burning sensation in the head, chills, cyanosis, diaphoresis, dyspnea, faintness or light-headedness, fatigue, fever, hives, itching or rash, neck pain or difficulty moving neck, tachycardia, wheezing. ■ Report chest pain or tightness, decreased urine output, difficulty passing urine, edema, fluid retention, shortness of breath, or sudden weight gain.

Maternal/Child:

Category C: use during pregnancy only if clearly needed. ■ Safety for use in breast-feeding not established. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Not tested for safety and effectiveness in the elderly. Use with caution. Incidence of renal insufficiency and other side effects may be increased due to age, potential for decreased organ function, and pre-existing medical conditions; see Precautions.

DRUG/LAB INTERACTIONS

Defer administration of **live virus vaccines** for approximately 6 months after administration of VIGIV. ■ Concurrent use with **nephrotoxic drugs** (e.g., aminoglycosides [e.g., gentamicin], amphotericin B [conventional], cidofovir [Vistide], rifampin [Rifadin]) may increase the risk of renal insufficiency. ■ Maltose in IVIG products has been shown to give falsely high blood glucose levels. Use could result in inappropriate doses of insulin, resulting in life-threatening hypoglycemia or untreated hypoglycemia masked by falsely elevated glucose readings. Review product information of the blood glucose testing system, including test strips, to determine if the system is appropriate for use with maltose-containing parenteral products. ■ Additional drug/lab interaction studies have not been completed.

SIDE EFFECTS

Headache and mild to moderate urticaria are most frequently observed. A full range of hypersensitivity symptoms, including anaphylaxis, is possible. Backache, dizziness, injection site reaction, nausea, and upper respiratory infections also occur. A precipitous hypotensive reaction can occur and is most commonly associated with a too-rapid rate of injection. Serious side effects reported with other IGIV products should be considered and include acute renal failure, acute tubular necrosis, osmotic nephrosis, and proximal tubular nephropathy (may result in death); aseptic meningitis syndrome; hemolytic anemia (reversible); increased BUN and SCr (may occur as soon as 1 to 2 days following infusion); noncarcinogenic pulmonary edema (transfusion-related acute lung injury [TRALI]); severe reactions (e.g., circulatory collapse, fever, loss of consciousness, nausea and vomiting, sudden onset of dyspnea), which are more common in patients with antibody deficiencies; thromboembolism. Made from human plasma; the manufacturing process attempts to eliminate the risk of bloodborne viruses (e.g., hepatitis, HIV infection, Creutzfeldt-Jakob disease), but the potential for infection cannot be ruled out.

ANTIDOTE

Reduce rate or temporarily interrupt infusion for patient discomfort or any sign of adverse reaction. Reduce rate in patients at risk for renal insufficiency. Loop diuretics (e.g., furosemide) may be helpful in the management of fluid overload. If patient continues to experience adverse reactions after rate has been reduced, other IGIV preparations suggest premedicating with hydrocortisone 1 to 2 mg/kg 30 minutes before the immune globulin infusion. Pretreatment with acetaminophen and diphenhydramine may also be useful. Discontinue the drug immediately for any signs of a hypersensitivity reaction. Notify the physician. May be treated symptomatically and infusion resumed at slower rate if symptoms subside. Treat anaphylaxis immediately. Epinephrine, diphenhydramine, oxygen, vasopressors (e.g., dopamine), corticosteroids, and ventilation equipment must always be available. Manage TRALI with oxygen and ventilatory support. Resuscitate as necessary.

VANCOMYCIN HYDROCHLORIDE

(van-koh-**MY**-sin hy-droh-**KLOR**-eyed)
Antibacterial (tricylic-glycopeptide)
pH 2.5 to 5

USUAL DOSE

500 mg every 6 hours or 1 Gm every 12 hours. Administer each dose at a rate of 10 mg/min or over 60 minutes, whichever is longer. Normal renal function required.

Other sources recommend 15 to 20 mg/kg/dose (with a usual maximum of 2 Gm/dose) every 8 to 12 hours. In seriously ill patients with complicated infections, a loading dose of 25 to 30 mg/kg (actual body weight) may be administered.

Prevention of enterococcal endocarditis in selected penicillin-allergic patients having GI, biliary, or GU surgery or instrumentation (unlabeled):

Adults and adolescents:

AHA recommends 1 Gm IV before the procedure. Give gentamicin 1.5 mg/kg IV concurrently in high-risk patients (not to exceed 120 mg). Infusion must be administered over at least 60 minutes and should be completed within 30 minutes of starting the procedure. Gentamicin may not be necessary in moderate-risk patients. Vancomycin alone may be indicated in selected patients having dental procedures or upper respiratory tract surgery or instrumentation. Consult recent recommendations of the American Heart Association or the American Dental Association.

Treatment of patients with oxacillin-resistant staphylococcal endocarditis who have a native cardiac valve:

30 mg/kg/24 hr (not to exceed 2 Gm/day unless serum concentrations are inappropriately low) equally divided into 2 doses (15 mg/kg every 12 hours) for 6 weeks.

Treatment of patients with oxacillin-resistant endocarditis who have a prosthetic valve or other prosthetic material:

30 mg/kg/24 hr (not to exceed 2 Gm/day unless serum concentrations are inappropriately low) equally divided into 2 doses (15 mg/kg every 12 hours) for 6 weeks or longer. Given in conjunction with oral or IV rifampin 300 mg every 8 hours for 6 weeks or longer and IM or IV gentamicin 3 mg/kg/day equally divided into 2 to 3 doses (1 mg/kg every 8 hours or 1.5 mg/kg every 12 hours) during the first 2 weeks of vancomycin therapy.

Treatment of endocarditis caused by viridans streptococci or *Streptococcus bovis* in patients unable to take a beta-lactam antibiotic:

30 mg/kg/24 hr (not to exceed 2 Gm/day unless serum concentrations are inappropriately low) equally divided into 2 doses (15 mg/kg every 12 hours) for 4 weeks (native valve endocarditis) to 6 weeks (prosthetic valve endocarditis).

Treatment of enterococcal endocarditis when penicillin G or ampicillin cannot be used:

30 mg/kg/24 hr equally divided into 2 doses (15 mg/kg every 12 hours) for 6 weeks. Given in conjunction with IM or IV gentamicin 1 mg/kg every 8 hours for 6 weeks.

Perioperative prophylaxis in selected surgeries (e.g., cardiac, prosthetic valve, coronary artery bypass, joint replacement, craniotomy) when a cephalosporin cannot be used or there is a high incidence of methicillin-resistant staphylococci at the institution (unlabeled use):

15 mg/kg within 120 minutes before surgery; should be completed within 30 minutes before the start of surgery. May be repeated one or more times if surgery is prolonged or major blood loss occurs. Postoperative doses are considered generally unnecessary and are not recommended.

Prevention of neonatal Group B streptococcal disease:

Used for women with penicillin hypersensitivity who should not receive β-lactam anti-infectives or if resistance to clindamycin or erythromycin is known or suspected. 1 Gm every 12 hours until delivery. Initiate at the beginning of labor or rupture of membranes. Another source recommends 20 mg/kg/dose (maximum of 2 Gm/dose) every 8 hours from onset of labor until delivery.

PEDIATRIC DOSE

Pediatric patients 1 month of age or older:

10 mg/kg IV infused over at least 60 minutes every 6 hours. Another source recommends: ***Mild to moderate infections:*** 40 to 45 mg/kg/24 hr equally divided and given every 6 or 8 hours (10 to 11.25 mg/kg every 6 hours or 13.33 to 15 mg/kg every 8 hours). ***Severe infections:*** 45 to 60 mg/kg/24 hr equally divided and given every 6 or 8 hours (11.25 to 15 mg/kg every 6 hours or 15 to 20 mg/kg every 8 hours). 60 mg/kg/24 hr given in divided doses every 6 hours (15 mg/kg/dose) has been recommended for treatment of meningitis. Do not exceed 2 Gm in 24 hours.

Prevention of enterococcal endocarditis in selected penicillin-allergic patients having GI, biliary, or GU surgery or instrumentation:

20 mg/kg before the procedure. Give gentamicin 1.5 mg/kg concurrently in high-risk patients (not to exceed 120 mg). Gentamicin may not be necessary in moderate-risk patients. Infusion of vancomycin must be administered over at least 60 minutes and should be complete within 30 minutes of starting the procedure. Note comments about dental and upper respiratory surgery or instrumentation under Usual Dose.

NEONATAL DOSE

15 mg/kg as an initial dose. See Maternal/Child. Follow with 10 mg/kg. Adjust interval based on age and/or weight as follows:

Infants up to 1 week of age:

Give every 12 hours.

Infants 1 week to 1 month of age:

Give every 8 hours.

The American Academy of Pediatrics recommends 10 to 15 mg/kg. Adjust dose and interval based on weight and/or age as follows:

Postnatal Weight and Age	Dose and Interval
Less than 1.2 kg and under 7 days of age	15 mg/kg/dose every 18 to 24 hours
Less than 1.2 kg and 7 days of age or older	15 mg/kg/dose every 18 to 24 hours
1.2 to 2 kg and under 7 days of age	10 to 15 mg/kg/dose every 12 to 18 hours
1.2 to 2 kg and 7 days of age or older	10 to 15 mg/kg/dose every 8 to 12 hours
Over 2 kg and under 7 days of age	10 to 15 mg/kg/dose every 8 to 12 hours
Over 2 kg and 7 days of age or older	10 to 15 mg/kg/dose every 6 to 8 hours

DOSE ADJUSTMENTS

Reduce total daily dose in premature infants and elderly patients. Greater dose reductions than expected may be necessary in these patients because of impaired renal function. ■ Dose reduction required in impaired renal function. In all renally impaired patients (including functionally anephric and anuric patients), the initial dose should be no less than 15 mg/kg. After the initial dose, subsequent doses are reduced based on CrCl; ***see prescribing information.*** In patients with marked renal impairment, it may be more convenient to give a maintenance dose of 250 to 1,000 mg every several days rather than administering the drug on a daily basis. For anuria, subsequent doses of 1,000 mg every 7 to 10 days have been suggested. Monitoring of serum levels is recommended.

DILUTION

Available premixed and frozen, or reconstitute each 500-mg vial with 10 mL of SWFI. Each 500 mg must be further diluted with 100 mL of NS or D5W and given as an intermittent infusion. Also **compatible** in D5NS, LR, D5LR, D5 Normosol-M, Isolyte E, and acetated Ringer's injection. Concentrations greater than 5 mg/mL are not recommended. Also available in ADD-Vantage vials for use with ADD-Vantage infusion containers.

Storage:

Store vials at CRT. After reconstitution, vials may be stored in a refrigerator for 96 hours. Maintains potency for 2 weeks in D5W or NS. Solutions prepared from ADD-Vantage vials are stable for 24 hours at room temperature and for 14 days if refrigerated. However, good professional practice suggests that compounded admixtures should be administered as soon after preparation as possible. Frozen premixed containers should be stored at or below −20° C (−4° F). Thaw at RT or under refrigeration. Do not force thaw. Once thawed, product is stable for 72 hours at RT or for 30 days if refrigerated.

COMPATIBILITY

Several sources recommend not admixing with other drugs. They suggest it is **incompatible** with alkaline solutions (e.g., aminophylline, aztreonam, barbiturates, chloramphenicol, dexamethasone, sodium bicarbonate) and may form a precipitate with heavy metals. May inactivate aminoglycosides; should also not be combined in the same solution with albumin, selected cephalosporins, foscarnet, or selected penicillins; if administered concurrently, administer at separate sites or separate intervals (flush IV line with a **compatible** solution before and after administration).

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Severe hypotension, with or without flushing of the face, neck, chest, and extremities, and cardiac arrest can occur with too-rapid injection.

A single dose properly diluted (concentration of no more than 5 mg/mL) at a rate not to exceed 10 mg/min or 60 minutes, whichever is longer. Another reference suggests each 500-mg increment over a minimum of 30 minutes. This intermittent infusion is the preferred route of administration because of high incidence of thrombophlebitis.

Pediatric rate:

A single dose over a minimum of 60 minutes.

ACTIONS

A tricyclic glycopeptide antibiotic, it is bactericidal against gram-positive organisms. Bactericidal action results from the inhibition of cell wall synthesis. Also alters bacterial cell-membrane permeability and RNA synthesis. Well distributed in most body tissues and fluids, including pleural, pericardial, ascitic, and synovial fluids; in urine; in peritoneal dialysis fluid; and in atrial appendage tissue. Penetration into the CSF occurs when the meninges are inflamed. Half-life is 4 to 6 hours in patients with normal renal function. Vancomycin is excreted in biologically active form in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious or severe infections caused by susceptible strains of methicillin-resistant (beta-lactam–resistant) *Staphylococcus aureus* (MRSA). ■ Treatment of gram-positive infections in penicillin-allergic patients; for patients who cannot receive or who have failed to respond to other drugs, including the penicillins or cephalosporins; and for infections caused by vancomycin-susceptible organisms that are resistant to other antimicrobial drugs. ■ Empiric therapy when MRSA is suspected. ■ Treatment of staphylococcal endocarditis and other infections due to staphylococci, including septicemia, bone, lower respiratory tract, and skin and skin structure infections that do not respond or are resistant to other antibiotics. ■ Treatment of endocarditis caused by other gram-positive organisms. Depending on the causative organism, vancomycin may be used alone or in combination with other antimicrobial agents. ■ Parenteral form may be used orally for pseudomembranous colitis/staphylococcal enterocolitis caused by *C. difficile*.

Unlabeled uses:

Prophylaxis against enterococcal endocarditis in moderate or high-risk (prosthetic heart valves, congenital or rheumatic heart disease) penicillin-allergic patients undergoing GI, biliary, or GU surgery or instrumentation.

CONTRAINDICATIONS

Known hypersensitivity to vancomycin. Solutions containing dextrose may be contraindicated in patients with allergies to corn or corn products.

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, vancomycin should be used only to treat or prevent infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies necessary to determine susceptibility of the causative organism to vancomycin. ■ Prolonged use of drug may result in superinfection caused by overgrowth of nonsusceptible organisms. ■ Nephrotoxicity has occurred. Systemic vancomycin has resulted in acute kidney injury (AKI). Risk increases as serum levels increase and in patients with underlying renal impairment, patients with comorbidities, and patients receiving concomitant therapy with a drug known to be nephrotoxic. ■ Ototoxicity has been reported with vancomycin, mostly in patients receiving excessive doses, who have an underlying hearing loss, or who are receiving concomitant therapy with another ototoxic agent such as an aminoglycoside. It may be transient or permanent. Use with caution in patients with renal impairment. Risk of ototoxicity is increased by high, prolonged blood concentrations. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with vancomycin. ■ Risk of high sodium load with Vancomycin Injection, USP with Sodium Chloride, USP. Each 100 mL contains 0.9 Gm of sodium chloride. Avoid use of this formulation in patients with CHF, elderly patients, and patients requiring restricted sodium intake. ■ Oral vancomycin has a local effect only (e.g., in the bowel); not for systemic use. ■ Reversible neutropenia has been reported; see Monitor.

Monitor:

Monitor renal function in all patients receiving vancomycin; see Precautions. ■ Monitoring of serum levels may be indicated in patients at increased risk for developing nephrotoxicity and/or ototoxicity (e.g., patients with underlying renal dysfunction or changing renal function, patients receiving concomitant aminoglycosides [e.g., gentamicin]) or in patients receiving prolonged courses of therapy (e.g., treatment of endocarditis); see Drug/Lab Interactions. ■ Determine absolute patency of vein. Necrosis and sloughing will result from extravasation. The frequency and severity of thrombophlebitis may be minimized by slow infusion of vancomycin and by rotation of venous access sites. ■ Monitor BP during infusion. ■ Severe hypotension (with or without flushing of the face, neck, chest, and extremities) and cardiac arrest can occur with too-rapid injection (red man or red neck syndrome). ■ Auditory testing indicated with prolonged use. ■ Periodic monitoring of leukocyte count recommended in prolonged therapy. ■ See Drug/Lab Interactions.

Patient Education:

Report all side effects promptly. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Use during pregnancy only if clearly needed. ■ Safety for use in breast-feeding not established; discontinue breast-feeding. ■ Confirmation of desired serum concentrations suggested in pediatric patients. Neonates have immature renal function; blood levels may be excessive. In premature infants, vancomycin clearance decreases as postconceptional age decreases. Longer dosing intervals may be necessary, and close monitoring of vancomycin serum concentrations is recommended.

Elderly:

Clearance may be reduced; dosage reduction and monitoring required.

DRUG/LAB INTERACTIONS

Synergistic with **aminoglycosides** against many strains of *Staphylococcus aureus* and streptococci; see package insert. Combined use may increase risk of ototoxicity and nephrotoxicity. ■ Additive toxicities may occur with ***systemic or topical*** use of **other nephrotoxic, neurotoxic, or ototoxic drugs** (e.g., aminoglycosides, amphotericin B, bacitracin, cisplatin, colistin, ethacrynic acid, furosemide, polymyxin B). Use with caution in combination with vancomycin; serial monitoring of renal and auditory function indicated. ■ May enhance neuromuscular blockade with **nondepolarizing muscle relaxants** (e.g., pancuronium). ■ Frequency of infusion-related reactions, including erythema, flushing, hypotension, pruritus, and urticaria, increases with concomitant administration of **anesthetic agents**. This infusion-related reaction may be minimized by administering vancomycin as a 60-minute infusion before anesthetic induction. Concomitant administration of vancomycin and anesthetic agents has been associated with erythema and histamine-like flushing in pediatric patients.

SIDE EFFECTS

Agranulocytosis, anaphylaxis, cardiac arrest, CDAD, chills, drug fever, dyspnea, eosinophilia, infusion-related events (anaphylactoid reactions, dyspnea, flushing of the upper body, hypotension, pain and muscle spasm of the chest and back, pruritus, urticaria, wheezing), interstitial nephritis, nausea, nephrotoxicity, neutropenia, ototoxicity (e.g., dizziness, hearing loss, tinnitus, vertigo), pain or inflammation at the injection site, pruritus, pseudomembranous colitis, rash (including exfoliative dermatitis, Stevens-Johnson syndrome, and vasculitis), red neck or red man syndrome, thrombocytopenia, and thrombophlebitis.

Post-Marketing:

Drug rash with eosinophilia and systemic symptoms (DRESS).

ANTIDOTE

Notify the physician of all side effects. Hearing loss may progress even if drug is discontinued. If minor side effects are progressive or any major side effect occurs, discontinue the drug, treat hypersensitivity reaction, or resuscitate as necessary. Temporarily discontinue or slow rate of infusion for an infusion-related reaction. Fluids, antihistamines, corticosteroids, and vasopressors (e.g., dopamine) may be required. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis or CAPD will not decrease blood levels in toxicity.

VASOPRESSIN INJECTION

(vay-so-**PRESS**-in in-**JEK**-shun)
Vasostrict
Hormone
Antidiuretic
pH 2.5 to 4.5

USUAL DOSE

Vasodilatory shock:

Postcardiotomy shock:

Initiate therapy at 0.03 units/min. Titrate to target BP as outlined in Dose Adjustments. Maximum dose is 0.1 units/min.

Septic shock:

Initiate therapy at 0.01 units/min. Titrate to target BP as outlined in Dose Adjustments. Maximum dose is 0.07 units/min.

GI variceal hemorrhage (unlabeled):

0.2 to 0.4 units/min as an infusion. Titrate as needed to a maximum dose of 0.8 units/min; maximum recommended duration is 24 hours at highest effective dose.

PEDIATRIC DOSE

All IV doses and uses are unlabeled; however, studies in pediatric patients have been conducted. See literature.

GI hemorrhage:

0.002 to 0.005 units/kg/min as an infusion. Gradually increase dose as needed to a maximum dose of 0.01 units/kg/min.

DOSE ADJUSTMENTS

Titrate up by 0.005 units/min at 10- to 15-minute intervals if needed until target BP response or maximum dose is reached. ■ Goal of treatment is optimization of perfusion to critical organs, but aggressive treatment can compromise perfusion of organs, such as the gastrointestinal tract, whose function is difficult to monitor. Titrate to the lowest dose compatible with a clinically acceptable response. ■ After target BP has been maintained for 8 hours without the use of catecholamines, taper vasopressin by 0.005 units/min every hour as tolerated to maintain target BP. ■ Lower-end initial dosing may be appropriate in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Available as a 1-mL multiple-dose vial containing 20 units/mL. Dilute in NS or D5W as outlined in the following chart.

Preparation of Vasopressin Diluted Solution

Fluid Restriction?	Final Concentration	Mix	
No	0.1 units/mL	2.5 mL (50 units)	500 mL
Yes	1 unit/mL	5 mL (100 units)	100 mL

Storage:

Refrigerate unopened vials between 2° and 8° C (36° and 46° F). Do not freeze. Storage conditions and expiration periods for vasopressin vials are summarized in the following chart. Mark revised 12-month expiration date on vials removed from refrigeration.

Storage Conditions and Expiration Periods for Vasopressin

	Unopened/Refrigerated (2° to 8° C [36° to 46° F])	Unopened/Room Temperature (20° to 25° C [68° to 77° F])	Opened (After First Puncture)
1-mL vial	Until manufacturer expiration date	12 months or until manufacturer expiration date, whichever is earlier	48 hours

Diluted solution may be stored for 18 hours at RT or 24 hours under refrigeration.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Infusion:

See Usual Dose for recommended rates for each diagnosis. Use of a central venous catheter is recommended. Titrate rate so that perfusion remains adequate while BP is optimized. Do not discontinue abruptly; see Dose Adjustments.

ACTIONS

A polypeptide hormone that causes contraction of vascular and other smooth muscles and antidiuresis. The vasoconstrictive effects of vasopressin are mediated by vascular V_1 receptors. The antidiuretic effects are mediated by vascular V_2 receptors. At therapeutic doses, exogenous vasopressin elicits a vasoconstrictive effect in most vascular beds, including the splanchnic, renal, and cutaneous circulation. It also triggers contractions of smooth muscles in the GI tract mediated by muscular V_1 receptors and by the release of prolactin and ACTH via V_3 receptors. At lower concentrations typical for the antidiuretic hormone, vasopressin inhibits water diuresis via renal V_2 receptors. In patients with vasodilatory shock, vasopressin increases systemic vascular resistance and mean arterial BP and reduces the dose requirements for norepinephrine. The pressor effect is proportional to the infusion rate. Vasopressin tends to decrease heart rate and cardiac output. Onset of action is rapid, with peak effects occurring in 15 minutes.

Pressor effects fade within 20 minutes after stopping an infusion. There is no evidence of tachyphylaxis or tolerance to the pressor effect of vasopressin. Predominantly metabolized in the liver and kidney to inactive metabolites. Excreted in the urine, primarily as inactive metabolites.

INDICATIONS AND USES

To increase BP in adults with vasodilatory shock (e.g., postcardiotomy shock or septic shock) who remain hypotensive despite fluids and catecholamines.

Unlabeled uses:

Gastroesophageal variceal hemorrhage; in-hospital cardiac arrest (in combination with epinephrine and methylprednisolone).

CONTRAINDICATIONS

Hypersensitivity to 8-L-arginine vasopressin or chlorobutanol.

PRECAUTIONS

Use in patients with impaired cardiac response may worsen cardiac output. ■ Use with caution in patients with vascular disease, especially coronary artery disease; may cause cardiac ischemia. Small doses may precipitate anginal pain, and larger doses may cause myocardial infarction. ■ May cause ischemia of other organs (e.g., GI tract, kidneys); use lowest effective dose. ■ May produce water intoxication; use with caution in patients with asthma, epilepsy, heart failure, migraine, renal impairment, or any condition in which a rapid addition to extracellular water could be hazardous.

Monitor:

Monitor BP, HR, and ECG. ■ Monitor fluid and electrolyte status, serum and urine sodium, urine specific gravity, urine and serum osmolality, and urine output. ■ Monitor IV site very closely, especially if it is a peripheral site; a central venous catheter is preferred. Produces intense vasoconstriction. Avoid extravasation; vasoconstriction that may result in severe tissue necrosis and gangrene can occur. ■ Use an indwelling urinary catheter to confirm urine output and monitor closely. ■ Fluid restriction may be indicated; initial signs of water intoxication include drowsiness, listlessness, and headache and can rapidly progress to coma and convulsions. ■ See Rate of Administration, Precautions, and Drug/Lab Interactions.

Maternal/Child:

Category C: safety for use during pregnancy not established; use only if clearly needed. ■ May produce tonic uterine contractions that could threaten the continuation of pregnancy. ■ Increased clearance of vasopressin in the second and third trimesters of pregnancy may necessitate the use of higher doses for treatment of postcardiotomy or septic shock. ■ Safety for use during breast-feeding not established. ■ Safety and effectiveness for use in pediatric patients with vasodilatory shock not established.

Elderly:

See Precautions; elderly patients may be more sensitive to adverse effects. ■ Dose selection should be cautious in elderly patients; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Vasodilators (e.g., nitroglycerin, nitroprusside sodium) counteract the vasoconstrictive effects of vasopressin. ■ Concomitant use with **catecholamines** (e.g., epinephrine, norepinephrine) is expected to result in an additive effect on mean arterial BP and other hemodynamic parameters. ■ **Indomethacin** may prolong the effect of vasopressin. ■ Use with ganglionic blocking agents may increase the effect of vasopressin on mean arterial BP. ■ **Furosemide** increases the effect of vasopressin on osmolar clearance and urine flow. ■ Use with **drugs suspected of causing SIADH** (e.g., selective serotonin reuptake inhibitors, tricyclic antidepressants, haloperidol, chlorpropamide, enalapril, methyldopa, pentamidine, vincristine, cyclophosphamide, ifosfamide, felbamate) may increase the pressor effect in addition to the antidiuretic effect of vasopressin. ■ Use with **drugs suspected of causing diabetes insipidus** (e.g., demeclocycline, lithium, foscarnet, clozapine) may decrease the pressor effect in addition to the antidiuretic effect of vasopressin.

SIDE EFFECTS

The most common adverse reactions include bradycardia, decreased cardiac output, hyponatremia, ischemia (coronary, digital, mesenteric, skin), and tachyarrhythmias. Other reported adverse reactions include acute renal insufficiency, angina, atrial fibrillation, decreased platelets, gangrene, headache, hemorrhagic shock, hypersensitivity reactions, increased bilirubin, intractable bleeding, ischemic lesions, and right heart failure.

Overdose:

Hyponatremia, ischemia (coronary, mesenteric, peripheral), nonspecific GI symptoms, rhabdomyolysis, and ventricular tachyarrhythmias.

ANTIDOTE

Monitor patient carefully. Notify physician of any side effect. Monitor fluid intake and urine output to ensure adequate hydration. Extravasation and/or ischemia at the injection site should be reported immediately to prevent tissue necrosis and gangrene. If extravasation occurs, stop the infusion immediately and disconnect, leaving cannula in place. Gently aspirate extravasated solution. Elevate extremity and initiate treatment of extravasation with phentolamine. If water intoxication should occur, treat with water restriction and discontinue vasopressin. If possible, discontinue gradually as described in Rate of Administration to prevent a rapid fall in BP. Direct pressor effects will resolve within minutes of withdrawal of treatment.

VECURONIUM BROMIDE BBW

(veh-kyour-**OH**-nee-um **BRO**-myd)
Norcuron 🍁

Neuromuscular blocking agent (nondepolarizing)
Anesthesia adjunct
pH 3.5 to 4.5

USUAL DOSE

Adjunct to general anesthesia:

Must be individualized, depending on previous drugs administered and degree and length of muscle relaxation required. To maximize clinical benefit and to minimize the possibility of overdose, the monitoring of muscle twitch response to peripheral nerve stimulation is advised.

Initial starting dose:

0.08 to 0.1 mg/kg (80 to 100 mcg/kg) of body weight initially as an IV bolus. Must be used with adequate anesthesia and/or sedation and after unconsciousness induced. One source suggests using IBW for obese patients (equal to or greater than 30% of IBW).

Maintenance dose:

Determine need for ***maintenance dose*** based on beginning symptoms of neuromuscular blockade reversal determined by a peripheral nerve stimulator. ***IV bolus injection:*** 0.01 to 0.015 mg/kg (10 to 15 mcg/kg) will be required in approximately 25 to 40 minutes and every 12 to 20 minutes thereafter to maintain muscle relaxation. Higher doses (0.15 to 0.28 mg/kg) at longer intervals have been given with proper ventilation without causing adverse cardiac effects. ***Continuous infusion:*** 1 mcg/kg/min. Begin 20 to 40 minutes after initial bolus dose. Initiate infusion only after early evidence of spontaneous recovery from the bolus dose. Adjust infusion rate to maintain a 90% suppression of twitch response. (Average infusion rate: 0.8 to 1.2 mcg/kg/min.)

Support of intubated, mechanically ventilated, adult ICU patients (unlabeled):

Initial IV bolus dose of 0.08 to 0.1 mg/kg (80 to 100 mcg/kg) followed by a continuous IV infusion of 0.8 to 1.7 mcg/kg/min (usual range: 0.8 to 1.2 mcg/kg/min). To reduce the possibility of prolonged neuromuscular blockade and other possible complications that might occur after long-term use in the ICU, vecuronium should be administered in carefully adjusted doses by or under the supervision of experienced clinicians who are familiar with appropriate peripheral nerve stimulator muscle monitoring techniques.

PEDIATRIC DOSE

Adjunct to general anesthesia:

10 to 16 years of age:

See Usual Dose.

1 to 10 years of age:

May require an initial dose that is slightly higher than the initial adult dose, and maintenance doses may be required on a more frequent basis.

Under 1 year of age:

See Dose Adjustments and Maternal/Child.

DOSE ADJUSTMENTS

Reduce initial dose by 15% (i.e., 0.06 to 0.085 mg/kg) if administered more than 5 minutes after inhalation general anesthetics. If a maintenance vecuronium infusion is initiated in the presence of steady-state concentrations of enflurane or isoflurane, it may be necessary to reduce the infusion rate 25% to 60% 45 to 60 minutes after the intubating dose. Under halothane anesthesia, a reduction in infusion rate may not be necessary. ■ If intubation is performed using succinylcholine, a reduction of the initial dose of vecuronium to 0.04 to 0.06 mg/kg with inhalation anesthesia and to 0.05 to 0.06 mg/kg with balanced anesthesia may be required. Succinylcholine must show signs of wearing off before vecuronium is given. Use caution. ■ Reduced dose may be required with numerous drugs; see Drug/Lab Interactions. ■ Reduced dose may be required in renal or hepatic impairment. Preparation by dialysis before surgery is recommended for patients with renal failure. In an emergency surgery when dialysis cannot be accomplished, consider a lower initial dose. ■ Infants between 7 weeks and 1 year may require a slightly lower dose, and recovery time will be extended.

DILUTION

Each 10 mg must be reconstituted to 10 (20) mL with a **compatible** IV solution (e.g., SWFI or BWFI). May be given by IV injection, or 10 (20) mg may be further diluted to a final volume of 100 mL with NS, D5W, D5NS, or LR and given as an infusion of 0.1 (0.2) mg/mL concentration. Concentrations of 1 mg/mL have been used in the ICU setting or in fluid-restricted patients.

Storage:

Store dry powder in original carton at CRT and protect from light. When reconstituted with an IV solution without preservatives (e.g., SWFI), refrigerate, use within 24 hours, and discard unused product. When reconstituted with BWFI, store at RT or refrigerated and use within 5 days.

COMPATIBILITY

Manufacturer states, “Has an acid pH. Reconstituted vecuronium should not be mixed with alkaline solutions (e.g., barbiturates) in the same syringe or administered simultaneously during IV infusion through the same needle or the same IV line.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Adjunct to general anesthesia:

A single dose as an IV bolus over 30 to 60 seconds. If maintenance dose is given as an infusion, adjust rate to specific dose desired as outlined in Usual Dose.

Mechanical ventilation support in ICU:

See Usual Dose for specific rates and criteria.

ACTIONS

A nondepolarizing neuromuscular blocking agent about one-third more potent than pancuronium with a shorter duration of neuromuscular blockade. Acts by competing for cholinergic receptors at the motor end plate. Onset of action is within 1 minute and is dose dependent. Vecuronium produces good or excellent intubation conditions within 2.5 to 3 minutes and maximum neuromuscular blockade (paralysis) within 3 to 5 minutes. Under balanced anesthesia, clinically required neuromuscular blockade lasts approximately 25 to 30 minutes. Time to recovery to 25% of control (clinical duration) is approximately 25 to 40 minutes, and recovery is usually 95% complete at approximately 45 to 65 minutes after injection of the intubating dose. Up to three times the therapeutic dose has been given without significant changes of hemodynamic parameters in good-risk surgical patients. Excreted as metabolites in bile and urine. Crosses the placental barrier.

INDICATIONS AND USES

Adjunctive to general anesthesia, to facilitate endotracheal intubation and to relax skeletal muscles during surgery or mechanical ventilation.

Unlabeled uses:

To facilitate mechanical ventilation in ICU patients.

CONTRAINDICATIONS

Known hypersensitivity to vecuronium.

PRECAUTIONS

For IV use only. ■ Administered by or under the supervision of experienced clinicians who are familiar with its actions and the possible complications that might occur after its use. ■ Maintenance of an adequate airway and respiratory support is imperative. Appropriate emergency drugs and equipment for monitoring the patient and responding to any medical emergency must be readily available. ■ Use extreme caution in elderly patients, obese patients, and patients with cirrhosis, cholestasis, edematous states, or circulatory insufficiency; delay in onset or prolonged recovery is possible. ■ In patients with myasthenia gravis or Lambert-Eaton myasthenic syndrome, small doses may have profound effects; use of a small test dose and a peripheral nerve stimulator may be of value in monitoring the response to vecuronium. ■ Severe anaphylactic reactions have been reported with neuromuscular blocking agents; some have been fatal. Use caution in patients who have had an anaphylactic reaction to another neuromuscular blocking agent (depolarizing or nondepolarizing); cross-reactivity has occurred. ■ Long-term use in the ICU to facilitate mechanical ventilation may be associated with prolonged paralysis and/or skeletal muscle weakness. Symptoms consistent with disuse muscle atrophy can develop in patients immobilized for extended periods. In addition, ICU patients may experience acid-base and/or electrolyte imbalances, debilitation, hypoxic episodes, and/or the use of other drugs (e.g., broad-spectrum antibiotics, narcotics, steroids) that can prolong the effects of vecuronium. Careful monitoring with a peripheral nerve stimulator during administration and recovery is strongly recommended. ■ Patients with severe obesity or neuromuscular disease may pose airway and/or ventilator problems requiring special care; use caution. ■ Many drugs used in anesthetic practice have triggered malignant hyperthermia (MH). Data are insufficient to establish whether or not vecuronium is capable of triggering MH. ■ Vecuronium has no known effect on consciousness, the pain threshold, or cerebration (i.e., no analgesic or sedative properties). Patient may be conscious and completely unable to communicate by any means. Vecuronium administration must be accompanied by adequate anesthesia or sedation. Administer analgesics as needed.

Monitor:

This drug produces apnea. Continuous monitoring with controlled artificial ventilation with oxygen must be available at all times. Maintain a patent airway. ■ Use a peripheral nerve stimulator to monitor response to vecuronium and avoid overdose. ■ Have reversal agents available (e.g., edrophonium, neostigmine, pyridostigmine with atropine or glycopyrrolate); see Antidote. ■ Action is altered by dehydration, electrolyte imbalance, and acid-base imbalance. ■ Recovery time extended in infants 7 weeks to 1 year. ■ See Drug/Lab Interactions. ***Mechanical ventilation support in ICU:*** Physical therapy is recommended to prevent muscular weakness, atrophy, and joint contracture. Muscular weakness may be first noticed during attempts to wean patients from the ventilator.

Maternal/Child:

Category C: use in pregnancy only if use justifies potential risk to fetus. Has been used during cesarean section; monitor infant carefully. Action may be enhanced by magnesium administered for the management of toxemia of pregnancy. ■ Use caution during breast-feeding. ■ Safety for use in infants under 7 weeks of age has not been established. ■ Some preparations contain benzyl alcohol; do not use in premature infants. ■ See Dose Adjustments.

Elderly:

Differences in response compared to younger adults not observed. Lower-end initial doses may be appropriate based on the potential for decreased organ function and concomitant disease or drug therapy. ■ Duration of neuromuscular block may be prolonged.

DRUG/LAB INTERACTIONS

Potentiated by **acidosis, hypokalemia, calcium channel blockers, general anesthetics, many antibiotics** (e.g., clindamycin), **aminoglycosides, polypeptide antibiotics** (e.g., bacitracin, colistimethate), **tetracyclines, vancomycin, diuretics, diazepam and other muscle relaxants, magnesium**

sulfate, quinidine, and others. May need to reduce dose of vecuronium. Use with caution. ■ Effects may be decreased by **acetylcholine, alkalosis, anticholinesterases, azathioprine, carbamazepine, and phenytoin.** ■ **Succinylcholine** may enhance the neuromuscular blocking effect and duration of action of vecuronium and must show signs of wearing off before vecuronium is given. Use caution.

SIDE EFFECTS

The most common adverse reaction consists of an extension of the drug's pharmacologic action and may range from skeletal muscle weakness to profound and prolonged skeletal muscle paralysis resulting in respiration insufficiency or apnea. Muscular weakness and atrophy may occur with long-term use (1 to 3 weeks).

Post-Marketing:

Hypersensitivity reactions, including anaphylaxis, bronchospasm, erythema, hypotension, tachycardia, and urticaria.

ANTIDOTE

All side effects are medical emergencies. Treat symptomatically. Controlled artificial ventilation must be continuous until full muscle control returns. Edrophonium, pyridostigmine, or neostigmine given with atropine or glycopyrrolate will probably reverse the muscle relaxation. Resuscitate as necessary.

VEDOLIZUMAB

Entyvio
Integrin receptor antagonist
Monoclonal antibody
pH 6.3

USUAL DOSE

Pretreatment:

Updating of immunizations required, and pre-screening for tuberculosis (TB) may be indicated; see Monitor.

Vedolizumab:

300 mg as an IV infusion over 30 minutes at 0, 2, and 6 weeks and then every 8 weeks thereafter. Discontinue in patients who show no evidence of therapeutic benefit by Week 14. Consider pretreatment with standard medical therapy in patients who experience mild to moderate infusion-related reactions or hypersensitivity reactions; see Antidote.

DOSE ADJUSTMENTS

No dose adjustments indicated. ■ Pharmacokinetics in patients with renal or hepatic insufficiency has not been studied.

DILUTION

Available as a white to off-white lyophilized powder in a single-use vial containing 300 mg. Bring vial to room temperature before reconstitution. Reconstitute with 4.8 mL SWFI using a syringe with a 21- to 25-gauge needle. Direct the SWFI to the glass wall of the vial to avoid excessive foaming. Gently swirl the vial for at least 15 seconds to dissolve the powder. ***Do not vigorously shake or invert.*** Allow solution to sit for up to 20 minutes. May be gently swirled. If not fully dissolved, allow another 10 minutes. Do not use if not fully dissolved within 30 minutes. Solution should be clear or opalescent, colorless to light brownish yellow. Once dissolved, gently invert the vial 3 times. Using a syringe with a 21- to 25-gauge needle, immediately withdraw 5 mL (300 mg) from the vial and add to an infusion bag or bottle containing 250 mL of NS or LR. Mix gently.

Filters:

Specific information not available.

Storage:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Retain in original package to protect from light. Use reconstituted solution immediately or refrigerate for 8 hours (SWFI). Solutions diluted in NS may be stored for 12 hours at RT or for 24 hours refrigerated. Solutions diluted in LR should be used immediately if at RT or may be stored for 6 hours if refrigerated. All storage times include initial reconstitution, dilution, and administration time. Do not freeze vials, reconstituted solutions, or diluted solutions. Discard any unused portion.

COMPATIBILITY

Manufacturer states, “Do not add other medicinal products to the prepared infusion solution or intravenous infusion set.”

RATE OF ADMINISTRATION

Do not administer as an IV push or bolus; for IV infusion only.

Administer a single dose (300 mg) as an IV infusion equally distributed over 30 minutes.

Flush line before the infusion and after infusion is complete with 30 mL of NS or LR.

ACTIONS

A recombinant humanized monoclonal antibody, vedolizumab is an integrin receptor antagonist. It specifically binds to the α4β7 integrin and blocks the interaction of α4β7 integrin with mucosal addressin cell adhesion molecule-1 (MAdCAM-1) and inhibits the migration of memory T-lymphocytes across the endothelium into inflamed gastrointestinal parenchymal tissue. Does not bind to or inhibit function of the α4β1 and αEβ7 integrins and does not antagonize the interaction of α4 integrins with vascular cell adhesion molecule-1 (VCAM-1). The interaction of the α4β7 integrin with MAdCAM-1 has been implicated as an important contributor to the chronic inflammation that is a hallmark of ulcerative colitis and Crohn's disease. A reduction in GI inflammation has been observed in rectal biopsy specimens. Clearance depends on both linear and nonlinear pathways. Serum half-life is approximately 25 days.

INDICATIONS AND USES

Treatment of adults with moderately to severely active ulcerative colitis (UC) to induce and maintain clinical response and clinical remission, improve the endoscopic appearance of the mucosa, and achieve corticosteroid-free remission. ■ Treatment of adults with moderately to severely active Crohn's disease (CD) to achieve clinical response and clinical remission and corticosteroid-free remission. ■ Indicated in adults with UC and CD who have had an inadequate response to, lost response to, or were intolerant to a tumor necrosis factor (TNF) blocker or immunomodulator or who had an inadequate response with, were intolerant to, or demonstrated dependence on corticosteroids.

CONTRAINDICATIONS

Known serious or severe hypersensitivity reaction to vedolizumab or any of its excipients.

PRECAUTIONS

Do not administer as an IV push or bolus; for IV infusion only ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Has been associated with infusion-related reactions and hypersensitivity reactions, including anaphylaxis. Reactions may occur during or several hours after the infusion. ■ Effects on the immune system may increase the risk of infection, including opportunistic infection. ■ Not recommended for patients with active, severe infections until the infections are controlled. ■ Use caution in patients with a history of recurring severe infections. ■ Progressive multifocal leukoencephalopathy (PML) has been reported with another integrin receptor antagonist; see Monitor. ■ Elevations of transaminase and/or bilirubin have occurred. May be a predictor of severe liver injury that may lead to death or the need for a liver transplant; see Monitor. ■ Update all vaccinations before initiating treatment with vedolizumab. Non–live virus vaccines (e.g., influenza) may be administered if indicated. No data on the secondary transmission of infection by live virus vaccines. ■ As with all therapeutic proteins, there is the potential for immunogenicity. Anti-vedolizumab antibodies may develop and should be considered if there is an inadequate response or a reduced therapeutic effect to treatment.

Monitor:

Consider screening for tuberculosis (TB). ■ Monitor for S/S of a hypersensitivity reaction (e.g., bronchospasm, dyspnea, flushing, hypertension, rash, tachycardia, urticaria) during the infusion and for several hours after completion. ■ Assess neurologic status frequently. S/S associated with PML are diverse and occur over days to weeks. May include progressive weakness on one side of the body, clumsiness of the limbs, disturbances of vision, or changes in thinking, memory, and orientation leading to confusion and personality changes. Progression of deficits usually leads to severe disability or death over weeks to months. Withhold vedolizumab if PML is suspected; consultation with a neurologist is indicated. If PML is confirmed, discontinue vedolizumab permanently. ■ Monitor for S/S of liver injury (e.g., elevated bilirubin, elevated liver function tests, jaundice). Discontinue vedolizumab in patients with jaundice or other evidence of significant liver injury. ■ Monitor for S/S of infection.

Patient Education:

Read medication guide carefully. ■ Review medical conditions and medications with health care provider before beginning treatment. ■ Promptly report any new medical problems (e.g., new or sudden change in thinking, eyesight, balance, or strength). ■ Report infections. ■ Report any symptoms of infusion or hypersensitivity reactions immediately (e.g., difficulty breathing, dizziness, feeling faint, itching, nausea). ■ Discuss potential risks and benefits of treatment (e.g., risk of PML). ■ Report any symptoms that may indicate liver injury (e.g., anorexia, dark urine, fatigue, jaundice, right upper abdominal discomfort).

Maternal/Child:

Use during pregnancy only if the benefits to the mother outweigh the risk to the fetus. Published data suggest that the risk of adverse pregnancy outcomes in women with inflammatory bowel disease is associated with increased disease activity. Adverse pregnancy outcomes include preterm delivery, low-birth-weight infants, and infants small for gestational age at birth. A pregnancy exposure registry has been created. Contact manufacturer for information. ■ Data suggest that vedolizumab is secreted in human milk. Use caution if required during breast-feeding; effects on breast-fed infant and on milk production unknown. ■ Administration of vedolizumab during pregnancy could affect immune responses in the newborns and infants exposed in utero. Safety of administering live or live-attenuated vaccines in exposed infants is unknown. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Safety and effectiveness similar to that seen in younger adults.

DRUG/LAB INTERACTIONS

Because of the potential for increased risk of PML and other infections, avoid the concomitant use of vedolizumab with **natalizumab**. ■ Because of the increased risk of infections, avoid the concomitant use of vedolizumab with **TNF blockers** (e.g., infliximab). ■ Benefits must outweigh risks if **live virus vaccines** are to be administered concurrently with vedolizumab; see Precautions. ■ Prior treatment with **TNF blockers** (e.g., infliximab), coadministered **immunomodulators** (including azathioprine, 6-mercaptopurine, methotrexate), and coadministered **aminosalicylates** did not have a clinically meaningful effect on the pharmacokinetics of vedolizumab.

SIDE EFFECTS

Arthralgia, back pain, bronchitis, cough, fatigue, fever, headache, influenza, nasopharyngitis, nausea, oropharyngeal pain, pain in extremities, pruritus, rash, sinusitis, and upper respiratory tract infection are most common. Infusion-related reactions and hypersensitivity reactions, including anaphylaxis, have occurred. Other serious side effects include liver injury (e.g., hepatitis), malignancies, PML, and serious infections such as anal abscess, cytomegaloviral colitis, giardiasis, *Listeria* meningitis, salmonella sepsis, sepsis (some fatal), and tuberculosis.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically. Discontinue vedolizumab at the first sign of liver injury. Discontinue infusion if any S/S of a serious hypersensitivity or infusion reaction occur. Treat with epinephrine, corticosteroids, diphenhydramine, bronchodilators, and oxygen as indicated. In clinical trials, patients with mild to moderate infusion-related reactions or hypersensitivity reactions were pretreated with standard medical therapy (e.g., acetaminophen, antihistamines, and/or hydrocortisone) before the next infusion. Withhold vedolizumab if S/S suggestive of PML occur; if diagnosis is confirmed, discontinue permanently. Consider withholding vedolizumab if a severe infection occurs.

VERAPAMIL HYDROCHLORIDE

(ver-**AP**-ah-mil hy-droh-**KLOR**-eyed)
Calcium channel blocker
Antiarrhythmic
pH 4.1 to 6

USUAL DOSE

ECG and BP monitoring recommended.

Verapamil:

5 to 10 mg initially (0.075 to 0.15 mg/kg of body weight). May cause transient bradycardia or hypotension. 10 mg (0.15 mg/kg) may be repeated in 30 minutes if needed to achieve appropriate response. Maximum total dose is 20 mg. AHA recommendation is 2.5 to 5 mg as an initial dose. Repeat 5 to 10 mg if needed every 15 to 30 min. Maximum dose 20 mg. Alternately, give 5 mg every 15 min to a total dose of 30 mg.

PEDIATRIC DOSE

ECG and BP monitoring mandatory. See Maternal/Child.

Infants up to 1 year of age:

0.1 to 0.2 mg/kg of body weight (usually 0.75 to 2 mg). Repeat in 30 minutes if indicated.

1 to 15 years of age:

0.1 to 0.3 mg/kg (usually 2 to 5 mg). Do not exceed 5 mg. Repeat in 30 minutes if response not adequate. Repeat dose should not exceed 10 mg as a single dose.

DOSE ADJUSTMENTS

Reduced dose may be required in hepatic or renal disease, especially with repeat dosing. ■ Dose selection should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy. ■ See Drug/Lab Interactions.

DILUTION

IV injection:

May be given undiluted through Y-tube or three-way stopcock of tubing containing D5W, NS, or Ringer's solution for infusion.

Filters:

No data available from manufacturer.

Storage:

Store between 15° and 30° C (59° and 86° F). Protect from light and freezing. Do not use if discolored or particulate matter present. Discard unused solution.

COMPATIBILITY

Manufacturer states, "Not recommended for dilution with sodium lactate in polyvinyl chloride bags. Will precipitate in any solution with a pH greater than 6." Lists as **incompatible** with albumin, amphotericin B (conventional), hydralazine, sulfamethoxazole/trimethoprim.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

A single dose over a minimum of 2 minutes for adults and pediatric patients. Extend to 3 minutes in the elderly.

ACTIONS

A calcium antagonist. It inhibits calcium (and possibly sodium) ion influx through slow channels into conductile and contractile myocardial cells and vascular smooth muscle cells. Slows conduction through the AV node, prolongs effective refractory period within the AV node, and reduces ventricular rates in patients with atrial flutter and/or atrial fibrillation and a rapid ventricular response. Prevents re-entry phenomena through the AV node. Reduces myocardial contractility, afterload, arterial pressure, systemic vascular resistance, and oxygen demand. Effective within 3 to 5 minutes. Hemodynamic effects last about 20 minutes, but antiarrhythmic effects may last up to 6 hours. Does not alter total serum calcium levels. Metabolized in the liver. Half-life range is 2 to 5 hours. Crosses the placental barrier. Excreted in urine and feces. Secreted in breast milk.

INDICATIONS AND USES

Treatment of supraventricular tachyarrhythmias, including (1) conversion to normal sinus rhythm of paroxysmal supraventricular tachycardia, including those associated with accessory bypass tracts (Wolff-Parkinson-White [WPW] and Lown-Ganong-Levine [LGL] syndromes); and (2) temporary control of rapid ventricular rate in atrial flutter or atrial fibrillation (except when the atrial flutter and/or atrial fibrillation are associated with accessory bypass tracts [WPW and LGL syndromes]).

Unlabeled uses:

Alternative drug after adenosine to terminate re-entry SVT with narrow QRS complex and adequate BP and preserved LV function (AHA guidelines).

CONTRAINDICATIONS

Patients with atrial fibrillation or flutter and an accessory bypass tract (e.g., Wolff-Parkinson-White or Lown-Ganong-Levine syndromes), cardiogenic shock, congestive heart failure (severe) unless secondary to supraventricular tachyarrhythmia treatable with verapamil, known hypersensitivity to verapamil, second- or third-degree AV block (unless functioning artificial pacemaker is in place), severe hypotension, sick sinus syndrome (unless functioning artificial pacemaker in place), patients receiving IV beta-adrenergic blocking drugs (e.g., propranolol) within a few hours, and ventricular tachycardia.

PRECAUTIONS

Administer in a facility with adequate personnel, equipment, and supplies to monitor the patient and respond to any medical emergency. A small fraction (less than 1%) of patients may respond with life-threatening adverse responses, including rapid ventricular rate in atrial flutter/fibrillation with an accessory bypass tract, marked hypotension, or extreme bradycardia/asystole. ■ Valsalva maneuver is recommended before use of verapamil in paroxysmal supraventricular tachycardia if clinically appropriate. ■ May produce hypotension. Usually transient and asymptomatic, but can cause dizziness. ■ Has rarely caused second- and third-degree AV block and, in extreme cases, asystole. More common in patients with sick sinus syndrome (SA nodal disease); see Elderly. ■ Caution required in hepatic and renal disease, especially if repeated dosing is required. ■ Use extreme caution in patients with hypertrophic cardiomyopathy. ■ May cause marked hemodynamic deterioration and ventricular fibrillation in patients with wide-complex ventricular tachycardia. ■ When heart failure is not severe or rate related, it should be controlled with digoxin and diuretics before using verapamil. ■ Patients with pulmonary wedge pressure above 20 mm Hg and/or ejection fraction below 30% may experience acute worsening of heart failure. ■ May precipitate respiratory muscle failure in patients with muscular dystrophy. ■ May increase intracranial pressure during anesthesia induction in patients with supratentorial tumors. Use caution and monitor closely. ■ Reduction of myocardial contractility may worsen CHF in patients with severe left ventricular dysfunction.

Monitor:

Continuous ECG and BP monitoring recommended. ■ Emergency resuscitation drugs and equipment must always be available. ■ Maintain bed rest until effects on HR, BP, and potential dizziness are evaluated. ■ See Drug/Lab Interactions.

Maternal/Child:

Category C: safety for use in pregnancy not yet established; use only when clearly indicated. ■ Discontinue breast-feeding. ■ Controlled studies have not been conducted in pediatric patients. Has been used in pediatric patients, including infants and newborns. Results of treatment were similar to those in adults. However, in rare instances severe hemodynamic side effects (e.g., bradycardia, hypotension, or a rapid ventricular rate in atrial flutter/fibrillation) have occurred in infants and neonates. Use caution and monitor closely.

Elderly:

May have an increased hypotensive effect; see Rate of Administration. ■ Half-life may be prolonged; see Dose Adjustments. ■ Elderly patients are more likely to have sick sinus syndrome, which may increase the risk of second- or third-degree AV block, bradycardia and, in extreme cases, asystole.

DRUG/LAB INTERACTIONS

Potentiates **digoxin;** lower dose may be appropriate. Both drugs slow AV conduction. Monitor for AV block and bradycardia. ■ Do not give concomitantly (within a few hours) with **IV beta-adrenergic blocking drugs**; see Contraindications. Both drugs depress myocardial contractility and AV node conduction; monitor patient closely. Use with extreme caution with **oral or ophthalmic beta-blockers.** ■ Do not administer **disopyramide** within 48 hours before or 24 hours after verapamil. ■ Use caution with **inhalation anesthetics.** Both depress cardiovascular activity. Titrate each carefully to avoid excessive cardiovascular depression. ■ Coadministration with **amiodarone** may result in bradycardia, hypotension, and decreased cardiac output. Monitor closely. ■ Potentiates **cyclosporine, carbamazepine, and theophyllines.** Monitor serum levels of these drugs and adjust dose as needed. ■ Potentiates **nondepolarizing muscle relaxants** (e.g., vecuronium); dose reduction of either drug may be required. ■ Metabolism may be decreased and serum concentrations may be increased by **itraconazole**. ■ Verapamil may increase serum concentrations of **dofetilide**. One source says avoid use; another says concurrent use contraindicated. ■ Avoid concomitant use of **ivabradine** and verapamil. Concurrent use increases serum concentrations of ivabradine, which may exacerbate bradycardia and conduction disturbances. ■ Verapamil may increase serum concentrations of **HMG-CoA reductase inhibitors, imipramine, sirolimus, and tacrolimus**. Monitor serum levels and/or monitor for S/S of toxicity; adjust dose as needed. ■ Concomitant use of **HMG-CoA reductase inhibitors** has been associated with reports of myopathy and rhabdomyolysis. In patients receiving verapamil, limit dose of simvastatin to 10 mg daily and limit lovastatin dose to 40 mg daily. Dose reductions for other HMG-CoA reductase inhibitors may also be required. ■ May increase effects of certain **benzodiazepines** (e.g., midazolam, triazolam) and **buspirone**; monitor and adjust doses as indicated. ■ May cause excessive hypotension with **other antihypertensive drugs** (vasodilators and diuretics). ■ Serum concentrations and effectiveness of verapamil may be decreased by **barbiturates, calcium salts,** and **phenytoin**. ■ Concomitant use with **IV dantrolene** may result in cardiovascular collapse. ■ Use caution with **quinidine**; may cause hypotension. ■ Highly protein bound; use with caution with **other highly protein-bound drugs** (e.g., oral hypoglycemics, warfarin). ■ Variable effects when administered with **lithium.** Has caused decreased effectiveness of lithium and may cause neurotoxicity. ■ Monitor heart rate with concurrent use of verapamil with **clonidine;** has resulted in sinus bradycardia requiring pacemaker insertion. ■ **Grapefruit juice** may affect certain enzymes of the P_{450} enzyme system and increase the serum concentrations of verapamil and should be avoided.

SIDE EFFECTS

Abdominal discomfort, asystole, bradycardia, dizziness, headache, second- and third-degree heart block, heart failure, hypersensitivity reactions (including anaphylaxis, bronchospasm/laryngospasm, itch, urticaria), rapid ventricular rate (Wolff-Parkinson-White and Lown-Ganong-Levine syndromes), hypotension (symptomatic), increased ventricular response in atrial flutter, nausea, PVCs, skin eruptions (including rare reports of erythema multiforme), seizures (rare), tachycardia (severe).

ANTIDOTE

Discontinue verapamil and notify physician promptly if hypotension, bradycardia, or second- or third-degree heart block occurs. Keep physician informed of all side effects. Treatment will depend on clinical situation. Calcium chloride may reverse effects of verapamil and can be used in toxicity. Glucagon may also be used in toxicity; see glucagon monograph. Rapid ventricular response (due to antegrade conduction in atrial flutter/fibrillation with WPW or LGL syndromes) should respond to cardioversion, procainamide, and/or lidocaine. Treat bradycardia, AV block, and asystole with standard AHA protocol (atropine, pacing). Norepinephrine, calcium chloride, or dopamine will reverse hypotension. Treat hypersensitivity reactions or resuscitate as necessary. Not removed by hemodialysis.

VERTEPORFIN

(ver-teh-**POR**-fin)
Visudyne
Photosensitizing agent
Macular degeneration therapy adjunct

USUAL DOSE

A course is a ***two-stage process*** requiring administration of both drug and light. Each course may be repeated every 3 months as indicated. Body surface area, lesion size determination, and spot size determination of the choroidal neovascularization (CNV) are used by the retina specialist to calculate dosing of verteporfin. The greatest linear dimension of the lesion is estimated by fluorescein angiography and color fundus photography. The treatment spot size should be 1,000 microns larger than the greatest linear dimension of the lesion on the retina to allow a 500-micron border. The nasal edge of the treatment spot must be positioned at least 200 microns from the temporal edge of the optic disc.

First stage:

6 mg/M^2 of verteporfin as a single IV infusion.

Second stage:

Activation of verteporfin using a recommended light dose of 50 J/cm^2 of neovascular lesion administered at an intensity of 600 mW/cm^2 over 83 seconds. Initiate 689 ± 3 nm wavelength laser light delivery 15 minutes after the start of the verteporfin infusion. Light is delivered to the retina as a single circular spot via a fiber optic and a slit lamp, using a suitable ophthalmic magnification lens. Light dose, light intensity, ophthalmic lens magnification factor, and zoom lens setting are important parameters for the appropriate delivery of light to the predetermined treatment spot. Follow the laser system manuals for procedure setup and operation.

Concurrent bilateral treatment:

In patients who present with eligible lesions in both eyes without prior verteporfin therapy, treat only one eye (the most aggressive lesion) during the first course. One week after the first course, if no significant safety issues are identified, the second eye can be treated, using the same treatment regimen including a verteporfin infusion and light activation. Approximately 3 months later, both eyes can be evaluated, and concurrent treatment following a new verteporfin infusion can be started if both lesions still show evidence of leakage. When treating both eyes concurrently, the more aggressive lesion should be treated first, at 15 minutes after the start of infusion. Immediately at the end of light application to the first eye, the laser settings should be adjusted to introduce the treatment parameters for the second eye, with the same light dose and intensity as for the first eye, starting no later than 20 minutes from the start of the infusion.

DOSE ADJUSTMENTS

No adjustments required. See Precautions.

DILUTION

Specific techniques required; see Precautions. Reconstitute each vial of verteporfin with 7 mL of SWFI to provide 7.5 mL of opaque, dark-green solution containing 2 mg/mL. Withdraw the desired dose from the vial and further dilute with D5W to a total infusion volume of 30 mL.

Filters:

Use of a 1.2-micron in-line filter is required for administration.

Storage:

Store between 20° and 25° C (68° and 77° F). Reconstituted and diluted solution must be protected from light and used within 4 hours.

COMPATIBILITY

Manufacturer states, “May precipitate in saline solutions. Do not use NS or other parenteral solutions. Do not mix in same solution with other drugs.” Use only SWFI and D5W as listed under Dilution.

RATE OF ADMINISTRATION

A 30-mL infusion equally distributed over 10 minutes (3 mL/min) using an appropriate syringe pump and a 1.2-micron in-line filter.

ACTIONS

A light-activated drug (photosensitizing agent) for use in photodynamic therapy (PDT). Transported in the plasma by lipoproteins. Endothelial cells of the abnormal choroidal blood vessels, which have high concentrations of lipoprotein receptors, take up the lipoprotein-verteporfin complex. Light activation in the presence of O_2 induces a photochemical reaction, generating highly reactive singlet oxygen and reactive oxygen radicals that cause local damage to the neovascular endothelium. The damaged endothelium releases procoagulant and vasoactive factors through the lipo-oxygenase (leukotriene) and cyclo-oxygenase (eicosanoids such as thromboxane) pathways, resulting in platelet aggregation, fibrin clot formation, vasoconstriction, and ultimately, vessel occlusion. Verteporfin appears to preferentially accumulate in neovasculature, including choroidal neovasculature. However, animal models indicate that the drug is also present in the retina. Therefore, there may be collateral damage to retinal structures following photoactivation. Terminal elimination half-life of verteporfin is 5 to 6 hours. It is metabolized to a small extent by liver and plasma esterases and is eliminated primarily by the fecal route as unchanged drug. May be secreted in breast milk.

INDICATIONS AND USES

Treatment of patients with predominantly classic subfoveal choroidal neovascularization due to age-related macular degeneration (AMD), pathologic myopia, or presumed ocular histoplasmosis. Slows retinal damage; does not reverse loss of vision in eyes damaged by AMD. ■ Not recommended for use in treatment of predominantly occult subfoveal choroidal neovascularization; evidence insufficient.

CONTRAINDICATIONS

Patients with porphyria or a known hypersensitivity to any component of this preparation.

PRECAUTIONS

Use rubber gloves and eye protection during preparation and administration. Avoid any skin or eye contact because that area will become photosensitive. Wipe up spills with a damp cloth. Dispose of all contaminated materials in a polyethylene bag to avoid accidental contact by others. Protection from light will be necessary if accidental exposure or overexposure occurs. Note process in Patient Education. ■ Administered by or under the direction of the physician specialist with appropriate knowledge of the selected laser system. Facilities for monitoring the patient and responding to any medical emergency must be available. ■ Requires laser systems and a fiber-optic diffuser to activate. *Coherent Opal Photoactivator Laser Console and LaserLink Adapter, Zeiss VISULAS 690s laser and VISILINK PDT adapter, Ceralas I laser system and Ceralink Slit Lamp Adapter, and Quantel Activis laser console and the ZSL30 ACTTM, ZSL120 ACTTM, and HSBMBQ ACTTM slit lamp adapters* are the laser systems that have been tested for **compatibility** with verteporfin and are approved for delivery of a stable power output at a wavelength of 689 ± 3 nm. Use of **incompatible** lasers that do not provide the required characteristics of light could result in incomplete treatment due to partial photoactivation, overtreatment due to overactivation, or damage to surrounding normal tissue. ■ Following verteporfin administration, care should be taken to avoid exposure of skin or eyes to direct sunlight or bright indoor light for 5 days. If emergency surgery is necessary within 48 hours after treatment, as much of the internal tissue as possible should be protected from intense light. ■ Patients who experience severe decrease of vision of 4 lines or more within 1 week after treatment should not be retreated, at least until their vision completely recovers to pretreatment levels. Potential risk versus benefit of any subsequent treatment should be considered. ■ Use with caution in patients with moderate to severe hepatic impairment or biliary obstruction, and in anesthetized patients. There is no clinical experience with these patient populations. ■ Older patients, patients with dark irides, patients with occult lesions or patients with less than 50% classic CNV may be less likely to benefit from verteporfin therapy. ■ Safety and efficacy of verteporfin beyond 2 years has not been demonstrated; however, it has been used up to 5 years in extension studies.

Monitor:

Standard precautions should be taken to avoid extravasation (e.g., establish a free-flowing IV line in a large arm vein, preferably the antecubital vein). If extravasation occurs, the infusion should be stopped immediately and cold compresses applied. The extravasation area must be thoroughly protected from direct light until the swelling and discoloration have faded in order to prevent the occurrence of a local burn, which could be severe. Oral analgesics may be indicated. ■ Monitor patient during infusion. Verteporfin has caused a concentration-dependent increase in complement activation in human blood in vitro. S/S consistent with complement activation (chest pain, dyspnea, flushing, syncope) have been reported. ■ Patient should be re-evaluated every 3 months; if choroidal neovascular leakage is detected on fluorescein angiography, therapy should be repeated. ■ See Usual Dose, Precautions, Patient Education, and Drug/Lab Interactions.

Patient Education:

■ Must observe precautions to avoid exposure of skin and eyes to direct sunlight or bright indoor light for 5 days. Photosensitivity is due to residual drug, which is present in all parts of the skin. Ambient indoor light is beneficial as it gradually inactivates the remaining drug through a photobleaching reaction. Do not remain in a darkened room. Do expose skin to ambient indoor light. Avoid bright indoor light from examination lamps, dental lamps, operating room lamps, bright halogen lighting, and unshaded light bulbs. Limit time outdoors to necessary excursions and completely cover body with clothing and shade face before going out. Ultraviolet sunscreens are of no value because photoactivation is caused by visible light, not UV rays. Eyes will be sensitive to sun, bright lights, and car headlights; wear dark sunglasses with an average white light transmittance of less than 4%. ■ Visual disturbances may develop and interfere with the ability to drive or operate machinery. Avoid these activities as long as visual symptoms persist.

Maternal/Child:

Category C: use during pregnancy only if benefits justify potential risk to fetus. Effective contraception necessary for women of childbearing age. Has caused maternal and fetal toxicity in rats and rabbits. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Reduced treatment effect was seen with increasing age (75 years of age or older).

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. Based on the mechanism of action of verteporfin, many drugs used concomitantly could influence the effect of verteporfin therapy. ■ **Calcium channel blockers** (e.g., diltiazem [Cardizem], verapamil, nicardipine [Cardene]), **polymyxin B, or radiation therapy** could enhance the rate of verteporfin uptake by the vascular endothelium. ■ Use with **other photosensitizing agents** (e.g., griseofulvin, phenothiazines [e.g., prochlorperazine (Compazine)], sulfonamides [sulfisoxazole (Gantrisin)], ophthalmic solutions (AK-Sulf)], sulfonylurea hypoglycemic agents [tolbutamide], tetracyclines [doxycycline], thiazide diuretics [chlorothiazide (Diuril)]) could increase the potential for a photosensitivity reaction. ■ Compounds that quench active oxygen species or scavenge radicals (e.g., **dimethyl sulfoxide** [DMSO], **beta-carotene, ethanol, formate, mannitol**) would be expected to decrease verteporfin activity. ■ Effectiveness may be reduced by **drugs that decrease clotting** (e.g., heparin, alteplase [tPA]), **vasoconstriction** (e.g., nicardipine [Cardene]) **or platelet aggregation** (e.g., clopidogrel [Plavix], dipyridamole [Persantine]).

SIDE EFFECTS

The most frequently reported side effects are headache, injection site reactions (e.g., edema, extravasation, hemorrhage with discoloration, pain, and rashes), self-resolving photosensitivity, and visual disturbances (e.g., blurred vision, decreased visual acuity, and visual field defects). Less frequently reported side effects include abnormal white blood cell count (decreased or increased), albuminuria, anemia, arthralgia, arthrosis, asthenia, atrial fibrillation, back pain (primarily during infusion), blepharitis, cataracts, chest pain, conjunctivitis, constipation, decreased hearing, diplopia, dizziness, dry eyes, dyspnea, eczema, elevated liver function tests, eye hemorrhage (subconjunctival, subretinal, or vitreous), fever, flu-like syndrome, flushing, hyperesthesia, hypersensitivity reactions, hypertension, increased creatinine, lacrimation disorder, malaise, myasthenia, nausea, ocular itching, peripheral vascular disorder, pharyngitis, photosensitivity, pneumonia, prostatic disorder, pruritus, retinal detachment (nonrhegmatogenous), retinal or choroidal vessel nonperfusion, retinal pigment epithelial tear, severe vision loss (may be equivalent of 4 lines or more within 7 days of treatment and occur with or without subretinal/retinal or vitreous hemorrhage), sleep disturbance, sweating, syncope, urticaria, varicose veins, vasovagal reactions, and vertigo.

Overdose:

Overdose of drug and/or light may result in nonperfusion of normal retinal vessels with the possibility of severe decrease in vision that could be permanent. May also result in prolongation of the time during which the patient will be photosensitive.

ANTIDOTE

Keep the physician informed of all side effects; most will be treated symptomatically. In the event of an overdose of drug and/or light, extend the photosensitivity precautions for a time proportional to the overdose.

VESTRONIDASE ALFA-vjbk INJECTION BBW

(ves-**TRON**-i-dase **AL**-fa VJBK)
Mepsevii
Enzyme replenisher
(Beta-glucuronidase)
pH 6

USUAL DOSE

Premedication:

For patient comfort, the administration of a nonsedating antihistamine (e.g., cetirizine or loratadine), with or without an antipyretic medication (e.g., acetaminophen or ibuprofen), is recommended 30 to 60 minutes before the start of the infusion.

Vestronidase alfa-vjbk:

4 mg/kg as an IV infusion over 4 hours every 2 weeks. Infuse the first 2.5% of the total volume over the first hour. After the first hour, increase the infusion rate as tolerated in order to complete the infusion over the next 3 hours; see Rate of Administration.

PEDIATRIC DOSE

See Usual Dose.

DOSE ADJUSTMENTS

No dose adjustment recommended.

DILUTION

Available as a colorless to slightly yellow liquid in a single-dose vial containing 10 mg/5 mL (2 mg/mL). Determine the number of vials to be diluted based on the patient's actual weight and the recommended dose of 4 mg/kg using the following calculations:

Total dose (mg) = Patient's weight (kg) × 4 mg/kg

Total number of vials = Total dose (mg) ÷ 10 mg/vial

A 40-kg adolescent requiring 4 mg/kg would require a dose of 160 mg. The number of vials required would be 16. If necessary, round up to the next whole vial. After patient is weighed and the appropriate dose is calculated, remove sufficient vials from refrigerator and allow them to reach RT. Do not heat, microwave, or shake vials.

Volume (mL) of calculated dose = Total dose (mg) ÷ 2 mg/mL concentration

The total volume in the above example is 80 mL. The final solution should be a 1:1 dilution with NS. More than a 1:1 dilution may be used if additional infusion volume can be tolerated, taking into consideration the patient's cardiac function and fluid status. Select an empty infusion bag based on the total volume of the final solution as a 1:1 dilution. Thin translucent fibers may occur in the vestronidase alfa-vjbk solution. Discard if solution is discolored or contains particulate matter. Using an appropriately sized syringe and a sufficiently large needle (18 gauge) to minimize bubbles in the solution, slowly withdraw the calculated volume of the vestronidase alfa-vjbk solution from the appropriate number of vials. Avoid excessive agitation and any air or frothing. Slowly add the vestronidase alfa-vjbk solution to the infusion bag, taking care to avoid agitation and to ensure liquid-to-liquid contact without generating bubbles or turbulence. Slowly add NS equal to the volume of vestronidase alfa-vjbk solution to the infusion bag. Gently rock the infusion bag to ensure proper distribution of vestronidase alfa-vjbk. ***Do not shake the solution.***

Filters:

Use of an in-line, low–protein-binding, 0.2-micron filter required.

Storage:

Before use, refrigerate vials at 2° to 8° C (36° to 46° F). ***Do not freeze or shake.*** Protect from light. Use solution immediately after dilution, and complete the infusion within 42 hours from the time of dilution. If immediate use is not possible, diluted solution may be refrigerated for up to 36 hours followed by up to 6 hours at room temperature up to a maximum of 25° C (77° F). Discard any unused product.

COMPATIBILITY

Manufacturer states, “Do not infuse with other products in the infusion tubing. **Compatibility** with other products has not been evaluated.”

RATE OF ADMINISTRATION

Infuse the first 2.5% of the total volume over the first hour. After the first hour, increase the infusion rate as tolerated in order to complete the infusion over the next 3 hours. Use an infusion set equipped with an in-line, low–protein-binding, 0.2-micron filter to administer. Administer with an automated infusion pump or see prescribing information for a weight-based infusion rate schedule. Prime infusion line with vestronidase alfa-vjbk solution to ensure 2.5% of the total infusion volume is delivered to the patient during the first hour of the infusion. To avoid a rapid bolus of infused enzyme, ***do not flush the line containing vestronidase alfa-vjbk solution***. Because of the low infusion rate, additional saline may be added through a separate line (piggyback or Y-tube) to maintain sufficient intravenous flow to prevent clotting or line blockage.

ACTIONS

A recombinant form of human lysosomal beta-glucuronidase (GUS). It is intended to provide exogenous GUS enzyme for uptake into cellular lysosomes. Mannose-6-phosphate (M6P) residues on the oligosaccharide chains allow the enzyme to bind to cell surface receptors, leading to cellular uptake of the enzyme, targeting to lysosomes, and subsequent catabolism of accumulated GAGs (glycosaminoglycans) in affected tissues. Results in reduction of urinary excretion of GAGs (including chondroitin sulfate and dermatan sulfate), which is sustained with continued treatment. Elimination half-life is 155 ± 37 minutes (range: 51 to 213 minutes). Eliminated by degradation into small peptides and amino acids. Not expected to be eliminated through renal or fecal excretion.

INDICATIONS AND USES

Treatment of mucopolysaccharidosis type VII (MPS VII, Sly syndrome) in pediatric and adult patients. MPS VII is a lysosomal disorder characterized by a deficiency of GUS enzyme, which results in GAG accumulation in cells throughout the body and leads to multisystem tissue and organ damage.

Limitation of use:

Effect of vestronidase alfa-vjbk on the CNS manifestations of MPS VII has not been determined.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use in a facility with the ability to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, have been reported; see Monitor and Antidote. ■ A therapeutic protein product. Patients have developed anti–vestronidase alfa-vjbk antibodies (ADA). Neutralizing antibodies have also been detected. There is no correlation between ADA titer and neutralizing antibody development. In clinical trials, the presence of ADA titer did not appear to affect reduction in the pharmacodynamic marker urinary glycosaminoglycan (uGAG).

Monitor:

Observe closely for a hypersensitivity reaction, including anaphylaxis, during the infusion and for a minimum of 60 minutes after the infusion. May occur as early as the first dose. S/S included cyanosis, decreased oxygen saturation, hypotension, and respiratory distress. Discontinue infusion immediately for a severe systemic reaction, including anaphylaxis.

Patient Education:

Lifelong enzyme replacement therapy is required. ■ Promptly report S/S of a hypersensitivity reaction (e.g., chills, dizziness, fatigue, fever, headache, itching, nausea, rash, shortness of breath, wheezing). Reactions may occur during or after infusion. ■ Pretreatment with antihistamines and/or antipyretics may be used to prevent or lessen reactions.

Maternal/Child:

No data available for use in pregnant women. Consider benefit versus possible risk. ■ No data available on the presence of vestronidase alfa-vjbk in human milk, the effects on breast-fed infants, or the effects on milk production. Consider risk versus benefit. ■ Safety and effectiveness for use in pediatric patients under 18 years of age have been established.

Elderly:

Not known if elderly patients respond differently than do younger patients. Clinical trials did not include patients 65 years of age and over.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Anaphylaxis, diarrhea, infusion site extravasation, infusion site swelling, peripheral swelling, pruritus, and rash are most common. Anaphylaxis is the most serious reaction reported.

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. Based on the severity of the reaction, temporarily slow, interrupt, or discontinue the infusion for clinical evidence of a hypersensitivity reaction. Discontinue infusion immediately for a severe systemic reaction and/or anaphylaxis and treat with oxygen, epinephrine, antihistamines, vasopressors, corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Patients have tolerated subsequent infusions without recurrence of anaphylaxis. Resuscitate as necessary.

VINBLASTINE SULFATE BBW

(vin-**BLAS**-teen **SUL**-fayt)
VLB
Antineoplastic (mitotic inhibitor-vinca alkaloid)
pH 3.5 to 5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor. See Maternal/Child.

Auxiliary labeling required; see Precautions.

Vinblastine:

3.7 mg/M^2 initially. Administered once every 7 days, increasing the dose to specific amounts (5.5, 7.4, 9.25, 11.1 mg/M^2) by a single step each week until the WBC count is decreased to 3,000 cells/mm^3, remission is achieved, or a maximum dose of 18.5 mg/M^2 is reached. Maintenance dose is one step below any dose that causes leukopenia (3,000 cells/mm^3 or less), once every 7 to 14 days. Usually 5.5 to 7.4 mg/M^2. Continue treatment for 4 to 6 weeks. Up to 12 weeks often necessary.

PEDIATRIC DOSE

See Maternal/Child.

One source suggests 2.5 mg/M^2 initially. Use same procedure as for adult dose using steps to 3.75, 5, 6.25, and 7.5 mg/M^2. Maximum dose is 12.5 mg/M^2. Maintenance dose is calculated by same parameters as Usual Dose (above). Usually differs with each individual. Other sources suggest that initial doses vary depending on the schedule used, use of vinblastine as a single agent, or its use in a combination regimen. Some suggested doses are:

Letterer-Siwe disease (unlabeled):

As a single agent, an initial dose of 6.5 mg/M^2.

Hodgkin disease:

An initial dose of 6 mg/M^2 in combination with other chemotherapeutic agents.

Testicular cancer:

An initial dose of 3 mg/M^2 in combination with other chemotherapeutic agents.

DOSE ADJUSTMENTS

Reduce dose by 50% if serum bilirubin above 3 mg/dL. ■ Often used with other antineoplastic drugs and corticosteroids in reduced doses and/or extended intervals to achieve tumor remission.

DILUTION

Specific techniques required; see Precautions. Each 10 mg is diluted with 10 mL of NS for injection. 1 mg equals 1 mL. Also available in liquid form (1 mg/mL). May be given by IV injection or through Y-tube or three-way stopcock of a free-flowing IV infusion.

Storage:

Store in refrigerator before and after dilution. Potency maintained for 28 days after dilution if reconstituted with bacteriostatic NS.

COMPATIBILITY

Manufacturer suggests that the pH not be altered from between 3.5 to 5 by an additive or a diluent, and it recommends NS as a diluent and not admixing with other drugs in the same container.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Total desired dose, properly diluted, over 1 minute.

ACTIONS

An alkaloid of the periwinkle plant with antitumor activity. Cell cycle–specific for M phase. Thought to interfere with the metabolic pathways of amino acids. Sometimes pharmacologically effective without any noticeable improvement in symptoms of malignancy. Cell energy production and synthesis of nucleic acid may also be inhibited. Half-life is 24.8 hours. Metabolism mediated by the hepatic cytochrome P_{450} isoenzymes in the CYP 3A subfamily. Some excretion through bile and urine.

INDICATIONS AND USES

To suppress or retard neoplastic growth. Remission and probable cure have been achieved with bleomycin and cisplatin in testicular malignancies. Response has been noted in Hodgkin disease, non-Hodgkin lymphomas, choriocarcinoma, Kaposi's sarcoma, mycosis fungoides, breast and renal cell malignancies. ■ Used to treat many other malignancies.

CONTRAINDICATIONS

Bacterial infection or leukopenia below 3,000 cells/mm^3.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Usually administered by or under the direction of the physician specialist. ■ Manufacturer provides an auxiliary sticker labeled “Fatal if given intrathecally, for IV use only” and an overwrap labeled “Do not remove covering until moment of injection. Fatal if given intrathecally. For intravenous use only.” Each and every syringe containing a specific dose and prepared in advance of actual administration must be labeled with the provided auxiliary sticker and packaged in this overwrap. If intrathecal injection should occur, immediate neurosurgical intervention is required; consult package insert for immediate steps to be taken. ■ May cause corneal ulceration with accidental contact to the eye. ■ Use caution in presence of ulcerated skin areas, cachexia, or impaired liver function. ■ Leukocyte and platelet counts have fallen precipitously in patients with malignant-cell infiltration of the bone marrow following moderate doses of vinblastine. Further administration is not recommended. ■ Acute pulmonary reactions including acute shortness of breath and severe bronchospasm have been reported in patients receiving vinca alkaloids. Occurs most frequently when given in combination with mitomycin-C. Onset of reaction may occur minutes to hours after vinca administration and up to 2 weeks following the mitomycin dose.

Monitor:

WBC count must be checked before each dose. Must be above 4,000 cells/mm^3. ■ Determine absolute patency, quality of vein, and adequate circulation of extremity. Severe cellulitis may result from extravasation. Rinse syringe and needle with venous blood before withdrawal from the vein; see Antidote. ■ Leukopenia is dose-limiting toxicity. Nadir occurs 5 to 10 days after therapy. Recovery occurs within another 7 to 14 days. ■ Be alert for signs of bone marrow suppression or infection. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Thrombocytopenia is rare, but may occur in patients whose bone marrow has been impaired by prior radiation therapy or other bone marrow suppressants. If platelet count is less than 50,000/mm^3, initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Observe for increased uric acid levels; may require increased doses of antigout agents; allopurinol (Aloprim) preferred. ■ Maintain adequate hydration. ■ Prophylactic antiemetics may increase patient comfort. ■ See Drug/Lab Interactions.

Patient Education:

Avoid pregnancy; effective birth control recommended. ■ Report IV site burning or stinging promptly. ■ Report chills, fever, sore mouth, or throat promptly. ■ Maintain adequate hydration; avoid constipation. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: avoid pregnancy. May produce teratogenic effects on the fetus. Has a mutagenic potential. ■ Discontinue breast-feeding. ■ Do not use diluents containing benzyl alcohol in premature infants.

Elderly:

Leukopenic response may be increased in malnutrition or with skin ulcers.

DRUG/LAB INTERACTIONS

Inhibited by **some amino acids, glutamic acid, and tryptophan.** ■ Potentiated by **other bone marrow suppressants** (e.g., antineoplastics, radiation therapy). ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Acute pulmonary reactions can occur with **mitomycin-C;** see Precautions. ■ May inhibit effects of **phenytoin**; increased doses of phenytoin may be needed. ■ **Erythromycin** decreases metabolism and increases toxicity of vinblastine. ■ Use caution with **any drug that inhibits** P_{450} **enzymes** (e.g., calcium channel blockers, antifungal agents, bromocriptine, cimetidine, clarithromycin, cyclosporine, danazol, metoclopramide); may increase vinblastine blood levels and increase toxicity. ■ Effect of **bleomycin** is significantly enhanced if vinblastine is administered 6 to 8 hours before bleomycin administration.

SIDE EFFECTS

Usually dose related and not always reversible: abdominal pain, alopecia, anorexia, cellulitis, constipation, convulsions, diarrhea, dizziness, extravasation, gonadal suppression, headache, hemorrhage, ileus, leukopenia (severe), malaise, mental depression, myelosuppression, nausea, numbness, oral lesions, paresthesias, peripheral neuritis, pharyngitis, Raynaud's syndrome, reflex depression (deep tendon), skin lesions, thrombophlebitis, tumor site pain, vomiting, weakness.

ANTIDOTE

For extravasation, discontinue the drug immediately and administer into another vein. Hyaluronidase should be injected locally into extravasated area. Use a fine hypodermic needle. Elevate extremity. Moist heat may be helpful. Notify the physician of all side effects; symptomatic treatment is often indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Glutamic acid blocks toxicity of vinblastine but also blocks its antineoplastic activity.

VINCRISTINE SULFATE BBW ■ VINCRISTINE SULFATE LIPOSOME INJECTION BBW

(vin-**KRIS**-teen **SUL**-fayt) (vin-**KRIS**-teen **SUL**-fayt **LIP**-oh-sohm in-**JEK**-shun)
VCR, Vincasar PFS ■ Marqibo
Antineoplastic (mitotic inhibitor-vinca alkaloid)
pH 3.5 to 5.5 • pH not available

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies/assessment indicated; see Monitor.

Conventional Vincristine

Auxiliary labeling required; see Precautions.

Neurotoxicity appears to be dose related. Use extreme care in calculating and administering vincristine. Overdose may be fatal.

1.4 mg/M^2 administered once every 7 days. Various dosage schedules have been used with caution.

Marqibo (Liposomal Vincristine)

2.25 mg/M^2 as an IV infusion over 1 hour once every 7 days. Liposomal vincristine has different dosage recommendations than conventional vincristine. Verify drug name and dose before preparation and administration.

PEDIATRIC DOSE

Conventional Vincristine

Weight over 10 kg:

1.5 to 2 mg/M^2 once each week.

Weight 10 kg (22 lb) or less:

0.05 mg/kg of body weight once a week. See comments under Usual Dose.

Marqibo (Liposomal Vincristine)

Safety and effectiveness for use in pediatric patients not established.

DOSE ADJUSTMENTS

Conventional Vincristine:

In impaired hepatic function, reduce initial doses by 50% if direct bilirubin above 3 mg/dL. May be increased gradually based on individual response. ■ Usually given with other antineoplastic drugs and corticosteroids in reduced doses to achieve tumor remission. ■ See Drug/Lab Interactions.

Marqibo (Liposomal Vincristine)

Recommended Dose Modifications for Marqibo-Related Peripheral Neuropathy	
Severity of Peripheral Neuropathy Signs/Symptoms[a]	**Modification of Marqibo Dose and Regimen**
Patient develops Grade 3 (severe symptoms, limiting self-care activities of daily living [ADL][b]) or persistent Grade 2 (moderate symptoms, limiting instrumental ADL[c]) peripheral neuropathy.	Interrupt Marqibo. If the peripheral neuropathy remains at Grade 3 or 4, discontinue Marqibo. If the peripheral neuropathy recovers to Grade 1 or 2, reduce the Marqibo dose to 2 mg/M².
Patient has persistent Grade 2 peripheral neuropathy after the first dose reduction to 2 mg/M².	Interrupt Marqibo for up to 7 days. If the peripheral neuropathy increases to Grade 3 or 4, discontinue Marqibo. If peripheral neuropathy recovers to Grade 1, reduce the Marqibo dose to 1.825 mg/M².
Patient has persistent Grade 2 peripheral neuropathy after the second dose reduction to 1.825 mg/M².	Interrupt Marqibo for up to 7 days. If the peripheral neuropathy increases to Grade 3 or 4, discontinue Marqibo. If the toxicity recovers to Grade 1, reduce the Marqibo dose to 1.5 mg/M².

[a] Grading based on the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE), v4.0.

[b] Self-care ADL: Refers to bathing, dressing/undressing, feeding self, using the toilet, taking medications, not bedridden.

[c] Instrumental ADL: Refers to preparing meals, shopping for groceries and clothes, using telephone, managing money, etc.

DILUTION

Conventional Vincristine:

Specific techniques required; see Precautions. Apply auxiliary label and package in manufacturer-supplied overwrap; see Precautions. Available in preservative-free solutions (1 mg/mL). May be given by IV injection or through Y-tube or three-way stopcock of a free-flowing IV infusion. Occasionally further diluted in 50 mL or more NS or D5W and given as an infusion. To reduce the potential for fatal medication errors due to incorrect route of administration, vincristine should be diluted in a flexible plastic container and prominently labeled as indicated for intravenous use only.

Marqibo (Liposomal Vincristine):

Specific techniques required; see Precautions. Marqibo will be prepared in the pharmacy by a very specific process that takes approximately 60 to 90 minutes. Dedicated, uninterrupted time is required due to extensive monitoring of temperature and time required for preparation. When prepared according to directions, each single-dose vial contains 5 mg/31 mL (0.16 mg/mL). Refer to manufacturer's literature for a detailed outline of the preparation procedure. Contact manufacturer if questions arise about preparation.

Items required by the pharmacy to prepare Marqibo include:

- Marqibo kit
- Water bath*
- Calibrated thermometer (0° to 100° C)*
- Calibrated electronic timer*
- Sterile venting needle or other suitable device equipped with a sterile 0.2-micron filter
- 1-mL or 3-mL sterile syringe with needle, and a 5-mL sterile syringe with needle

*Manufacturer will send the water bath, calibrated thermometer, and calibrated electronic timer to the medical facility at the initial order of Marqibo and will replace them every 2 years.

Filters:

Marqibo (liposomal vincristine):

0.2-micron filter required during preparation; however, ***do not use with in-line filters***.

Storage:

Conventional vincristine:

Store in refrigerator. Retain in carton to protect from light. Store upright. Solutions diluted with NS to a concentration of 0.0015 to 0.08 mg/mL are stable for 24 hours when protected from light or for 8 hours under normal light at 25° C (77° F).

Marqibo (liposomal vincristine):

Store Marqibo kit in refrigerator at 2° to 8° C (36° to 46° F). ***Do not freeze.*** Once prepared, may be stored at CRT for no more than 12 hours.

COMPATIBILITY

Conventional Vincristine

Manufacturer suggests that the pH not be altered from between 3.5 to 5.5 by an additive or a diluent, and it recommends NS or D5W as a diluent and not admixing with other drugs in the same container.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

Marqibo (Liposomal Vincristine)

Manufacturer states, "Do not mix with other drugs."

RATE OF ADMINISTRATION

Conventional Vincristine

“Fatal if given intrathecally; for IV use only.”

IV injection:

Total desired dose, properly diluted, over 1 minute.

Infusion:

A single dose over 5 to 10 minutes or as a continuous infusion (based on specific protocols).

Marqibo (Liposomal Vincristine)

For IV use only; fatal if given by other routes. A single dose as an IV infusion equally distributed over 1 hour. Administer through a secure and free-flowing venous access line.

ACTIONS

Conventional Vincristine:

An alkaloid of the periwinkle plant with antitumor activity. Cell cycle–specific for the M phase. It binds to tubulin, altering the tubulin polymerization equilibrium and resulting in altered microtubule structure and function. It stabilizes the spindle apparatus, preventing chromosome segregation and triggering metaphase arrest and inhibition of mitosis. Well distributed except in spinal fluid. Extensively metabolized with a half-life of 85 hours. Primarily excreted through feces.

Marqibo (Liposomal Vincristine):

Vincristine encapsulated in sphingomyelin/cholesterol liposomes. Its mechanism of action, distribution, and elimination is similar to that of conventional vincristine.

INDICATIONS AND USES

Conventional Vincristine:

Treatment of acute leukemia. ■ Useful in combination with other oncolytic agents for Hodgkin disease, non-Hodgkin malignant lymphomas, rhabdomyosarcoma, neuroblastoma, and Wilms’ tumor.

Marqibo (Liposomal Vincristine):

Treatment of adults with Philadelphia chromosome-negative (Ph-) acute lymphoblastic leukemia (ALL) in second or greater relapse or adults whose disease has progressed following two or more antileukemia therapies. Indication based on overall response rate; clinical benefit such as improvement in overall survival not verified.

Unlabeled uses: Conventional vincristine:

Treatment of idiopathic thrombocytopenic purpura; treatment of Kaposi's sarcoma, breast and bladder cancer.

CONTRAINDICATIONS

Both formulations:

Demyelinating form of Charcot-Marie-Tooth syndrome.

Marqibo (liposomal vincristine):

Hypersensitivity to vincristine sulfate or any of the components of Marqibo.

PRECAUTIONS

Both Formulations:

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Sensory and motor neuropathies are common and cumulative. Risk of neurologic toxicity is greater in patients with pre-existing neuromuscular disorders or when other potentially neurotoxic drugs are coadministered; see Monitor. ■ Myelosuppression may require dose adjustment. ■ Tumor lysis syndrome leading to acute uric acid nephropathy has occurred; see Monitor.

Conventional Vincristine:

Manufacturer provides an auxiliary sticker labeled "Fatal if given intrathecally, for IV use only" and an overwrap labeled "Do not remove covering until moment of injection. For intravenous use only. Fatal if given by other routes." Each and every infusion bag or syringe containing a specific dose and prepared in advance of actual administration must be labeled with the provided auxiliary sticker and packaged in this overwrap. If intrathecal injection should occur, immediate neurosurgical intervention is required; consult package insert for immediate steps to be taken. ■ If central nervous system leukemia is diagnosed, additional agents may be required because vincristine does not appear to cross the blood-brain barrier in adequate amounts. ■ Acute shortness of breath and severe bronchospasm have been reported following administration of vinca alkaloids. These reactions occur most frequently when the vinca alkaloid is administered in combination with mitomycin-C. Onset of these reactions may occur minutes to several hours after the vinca alkaloid is injected and may occur up to 2 weeks after the dose of mitomycin. Progressive dyspnea requiring chronic therapy may occur. Reaction may require aggressive treatment, especially if pre-existing pulmonary dysfunction is present. Vincristine should not be readministered. ■ Use extreme caution in combination with radiation therapy. Should not be given to patients while they are receiving radiation therapy through radiation ports that include the liver. ■ May cause corneal ulceration with accidental contact to the eye; flush eyes with water immediately. ■ Use caution in pre-existing neuromuscular disease or impaired liver function. ■ Not recommended for use in patients receiving radiation therapy that involves the liver.

Marqibo (Liposomal Vincristine):

For IV use only; fatal if given by other routes. ■ Death has occurred with intrathecal administration. ■ Has different dose recommendations than conventional vincristine. Verify drug name and dose before preparation and administration to avoid overdose. ■ Constipation and bowel obstruction have occurred. ■ Can cause severe fatigue requiring dose delay, reduction, or discontinuation of therapy. ■ Fatal liver toxicity and elevated AST have occurred. ■ The influence of renal impairment and severe hepatic impairment has not been evaluated.

Monitor:

Both Formulations:

Monitor CBC and platelets, bilirubin, and liver function tests before therapy and at frequent intervals. ■ Determine absolute patency and quality of vein and adequate circulation of extremity. Severe cellulitis may result from extravasation; see Antidote. ■ Monitor neurologic status before therapy and at frequent intervals. Symptoms of neuropathy may include areflexia, arthralgia, burning sensation, cranial neuropathy, decreased vibratory sense, hyperesthesia, hypoesthesia, hyporeflexia, ileus, jaw pain, muscle spasm, myalgia, neuralgia, paresthesia, or weakness. ■ Be alert for signs of bone marrow suppression or infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Observe for increased uric acid levels; may require increased doses of antigout agents (allopurinol [Aloprim] preferred) and may require alkalinization of urine. Monitor for early signs of tumor lysis syndrome (e.g., flank pain and hematuria). ■ Maintain adequate hydration. ■ Prophylactic antiemetics may increase patient comfort. ■ Monitor for hyponatremia and inappropriate secretion of antidiuretic hormone (ADH); may require fluid limitation. ■ Institute a prophylactic bowel regimen to prevent potential constipation, bowel obstruction, and/or paralytic ileus. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See Drug/Lab Interactions.

Patient Education:

Both formulations:

Avoid pregnancy; nonhormonal birth control recommended. ■ Report IV site burning or stinging promptly. ■ See Appendix D, p. 1311. ■ Use adequate dietary fiber, hydration, stool softeners and, if necessary, laxatives to avoid constipation.

Maternal/Child:

Both formulations:

Category D: avoid pregnancy. Can cause fetal harm. ■ Discontinue breast-feeding.

Marqibo (liposomal vincristine):

Safety and effectiveness for use in pediatric patients not established.

Elderly:

Both formulations:

Neurotoxicity may be more severe (observe closely for constipation, ileus, and urinary retention). Dose selection should be cautious.

DRUG/LAB INTERACTIONS

Studies have not been conducted for Marqibo, but it is expected to have interactions similar to conventional vincristine. ■ Acute pulmonary reactions can occur with **mitomycin-C.** ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ May decrease levels and effectiveness of **digoxin and phenytoin.** Monitor serum levels of digoxin and phenytoin; increased doses of these drugs may be required. ■ A substrate for cytochrome P_{450} isoenzymes (CYP3A). Avoid concurrent use of **drugs known to inhibit cytochrome P_{450} isoenzymes** (e.g., atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir) and **inducers of cytochrome P_{450} enzymes** (e.g., carbamazepine, dexamethasone, phenobarbital, phenytoin, rifabutin, rifampin, St. John’s wort). ■ Although not yet studied, it is likely that there will be interactions, and concomitant use should be avoided with **inhibitors of P-gp** (e.g., amiodarone, clarithromycin, diltiazem, erythromycin, itraconazole, ketoconazole, protease inhibitors [e.g., nelfinavir, ritonavir], quinidine, sirolimus, tacrolimus) and **inducers of P-gp** (e.g., rifampin, St. John’s wort).

SIDE EFFECTS

Conventional Vincristine:

Frequently dose related and not always reversible: abdominal pain, alopecia, anemia (rare), ataxia, bronchospasm, cellulitis, constipation, convulsions, cranial nerve damage, diarrhea, dysuria, extravasation, fever, foot-drop, gonadal suppression, headache, hepatic veno-occlusive disease, hypersensitivity reactions (e.g., anaphylaxis, edema, rash), hypertension, hypotension, leukopenia (rare), muscle wasting, nausea, neuritic pain, oral lacerations, paralytic ileus, paresthesias, polyuria, reflex changes, sensory impairment, shortness of breath, SIADH, thrombocytopenia (rare), thrombophlebitis, tingling and numbness of extremities, upper colon impaction, uric acid nephropathy, vomiting, weakness, weight loss.

Marqibo (Liposomal Vincristine):

Anemia, constipation, decreased appetite, diarrhea, fatigue, febrile neutropenia, fever, insomnia, nausea, and peripheral sensory and motor neuropathy are most common. Asthenia, bowel obstruction, cardiac arrest, hypotension, ileus, increased AST, mental status changes, muscle weakness, neutropenia, pain, pneumonia, renal disorders, respiratory distress and/or failure, septic shock, staphylococcal bacteremia, and thrombocytopenia have also been reported. Extravasation, hepatic toxicity, and tumor lysis syndrome have occurred.

ANTIDOTE

For extravasation, discontinue the drug immediately and administer into another vein. Hyaluronidase may be injected locally into extravasated area. Use a fine hypodermic needle. Elevate extremity; moist heat may be helpful. Notify the physician of all side effects; symptomatic treatment is often indicated. Will probably reduce dose at earliest signs of neurologic toxicity (tingling and numbness of extremities). Discontinue for inappropriate ADH secretion or hyponatremia. Treat with fluid restriction and diuretics. Phenobarbital may be needed for convulsions. Use enemas or cathartics to treat constipation or prevent ileus. Folinic acid, 100 mg IV every 3 hours for 24 hours and then every 6 hours for at least 48 hours, may be helpful in overdose. Supportive measures still required. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Hemodialysis is not likely to be helpful in an overdose situation.

VINORELBINE BBW

(vin-**OR**-el-been)
Navelbine
Antineoplastic (mitotic inhibitor-vinca alkaloid)
pH 3.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Single agent:

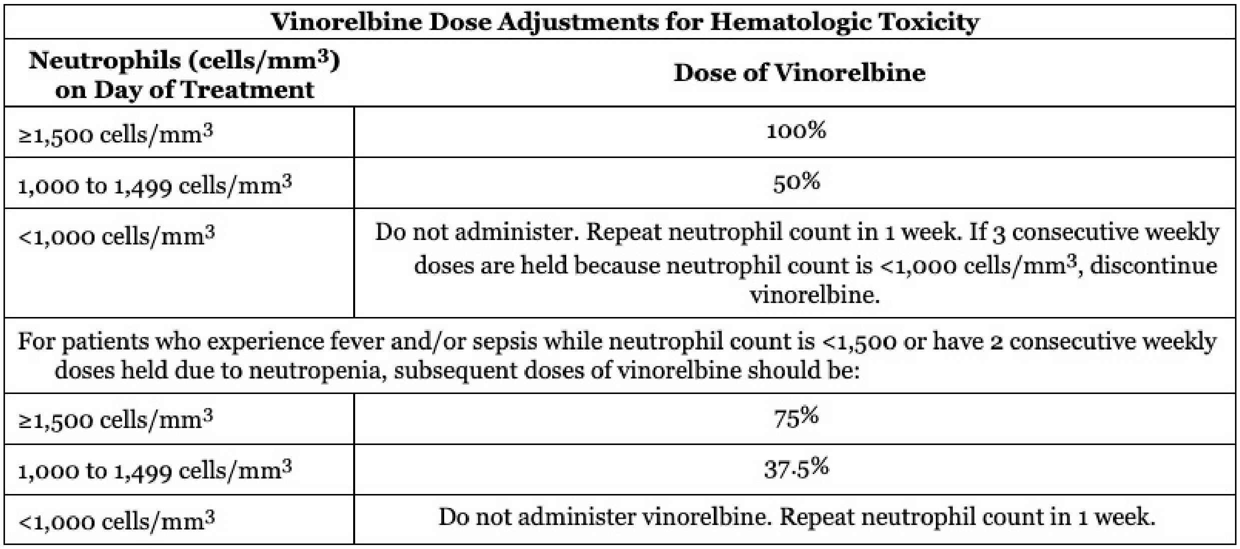
30 mg/M^2 administered IV over 6 to 10 minutes once each week until disease progression or dose-limiting toxicity.

In combination with cisplatin:

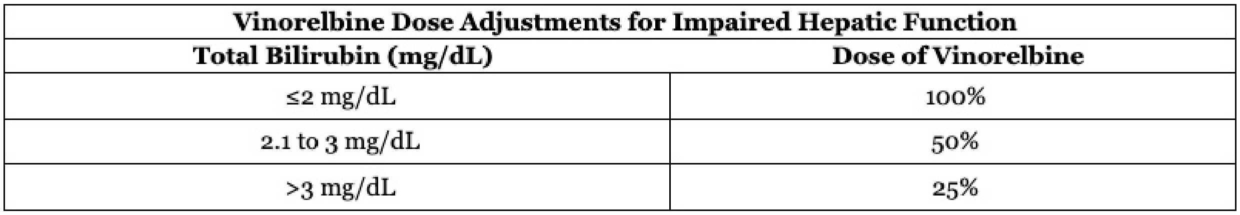
25 mg/M^2 administered as an IV injection or infusion over 6 to 10 minutes once weekly on Days 1, 8, 15, and 21 of a 28-day cycle in combination with cisplatin 100 mg/M^2 on Day 1 only of each 28-day cycle. **An alternative regimen** is vinorelbine 30 mg/M^2 as an IV injection or infusion over 6 to 10 minutes once a week in combination with cisplatin 120 mg/M^2 on Days 1 and 29, then every 6 weeks.

DOSE ADJUSTMENTS

Reduce or withhold dose based on hematologic toxicity or hepatic insufficiency (e.g., hyperbilirubinemia) on the day of treatment. For patients with both hematologic toxicity and hepatic insufficiency, administer the lower of the doses determined appropriate from the following charts.



Vinorelbine Dose Adjustments for Hematologic Toxicity	
Neutrophils (cells/mm³) on Day of Treatment	**Dose of Vinorelbine**
≥1,500 cells/mm³	100%
1,000 to 1,499 cells/mm³	50%
<1,000 cells/mm³	Do not administer. Repeat neutrophil count in 1 week. If 3 consecutive weekly doses are held because neutrophil count is <1,000 cells/mm³, discontinue vinorelbine.
For patients who experience fever and/or sepsis while neutrophil count is <1,500 or have 2 consecutive weekly doses held due to neutropenia, subsequent doses of vinorelbine should be:	
≥1,500 cells/mm³	75%
1,000 to 1,499 cells/mm³	37.5%
<1,000 cells/mm³	Do not administer vinorelbine. Repeat neutrophil count in 1 week.



Vinorelbine Dose Adjustments for Impaired Hepatic Function	
Total Bilirubin (mg/dL)	**Dose of Vinorelbine**
≤2 mg/dL	100%
2.1 to 3 mg/dL	50%
>3 mg/dL	25%

Appropriate dose reductions for cisplatin should be made when vinorelbine is used in combination. During one study, more than 50% of patients required a dose reduction of vinorelbine due to myelosuppression. ■ No dose adjustment is required for impaired renal function. ■ If Grade 2 or greater neurotoxicity develops, discontinue vinorelbine.

DILUTION

Specific techniques required; see Precautions.

Available as a colorless to pale-yellow solution in single-dose vials containing 10 mg/mL or 50 mg/5 mL. Each 10 mg (1 mL) must be further diluted with 4 to 19 mL NS, D5W, ½NS, D5/½NS, R, or LR. Desired concentration is 0.5 to 2 mg/mL (4 mL diluent yields 2 mg/mL concentration, 19 mL yields 0.5 mg/mL concentration). Other references recommend diluting a single dose to a minimum total volume of 100 mL. Must be given into the side-arm port of a free-flowing IV infusion.

Storage:

Refrigerate vials and protect from light. Do not freeze. Unopened vials are stable at room temperature for up to 72 hours. Diluted solution are stable for 24 hours under normal room light when stored at 5° to 30° C (41° to 86° F).

COMPATIBILITY

Manufacturer recommends mixing only with solutions listed under Dilution.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A vesicant; ensure proper needle or catheter position before administration to avoid extravasation.

Total desired dose, properly diluted over 6 to 10 minutes through the side-arm port of a free-flowing IV. After administration, flush with at least 75 to 125 mL of diluent solution. Inadequate flushing of the vein after administration may increase the risk of phlebitis.

ACTIONS

An antineoplastic agent. A semi-synthetic vinca alkaloid that interferes with microtubule assembly. Antitumor activity is thought to be due primarily to inhibition of mitosis at metaphase through its interaction with tubulin. Demonstrates high binding to platelets and lymphocytes. Elimination half-life is 27 to 43 hours. Metabolized in the liver by hepatic cytochrome P_{450} isoenzymes in the CYP3A subfamily. Excreted in feces and, to a lesser extent, in urine.

INDICATIONS AND USES

In combination with cisplatin for first-line treatment of patients with locally advanced or metastatic non–small-cell lung cancer (NSCLC). ■ As a single agent for treatment of patients with metastatic NSCLC.

Unlabeled uses:

Treatment of breast, cervical, and ovarian cancers.

CONTRAINDICATIONS

Manufacturer states "None." Do not administer to patients with pretreatment neutrophil counts less than 1,000 cells/mm^3.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ ***For IV administration only;*** inadvertent intrathecal administration of other vinca alkaloids has resulted in death. Syringes containing vinorelbine should be labeled "For IV use only. Fatal if given by other routes." ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be readily available. ■ Severe myelosuppression manifested by neutropenia, anemia, and thrombocytopenia occurs with vinorelbine. Serious infection, septic shock, hospitalization, and death may occur. Neutropenia is the major dose-limiting toxicity. ■ Drug-induced liver toxicity (manifested by elevations of AST and bilirubin) can occur. ■ Severe and fatal paralytic ileus, constipation, intestinal obstruction, necrosis, and perforation have been reported. Initiate a prophylactic bowel regimen, including routine use of stool softeners, hydration, and adequate dietary fiber intake, to mitigate these side effects. ■ Extravasation of vinorelbine can result in severe irritation, local tissue necrosis, and/or thrombophlebitis. ■ Sensory and motor neuropathies, some severe, have been reported. ■ Pulmonary toxicity, including severe acute bronchospasm, interstitial pneumonitis, and ARDS has been reported. Deaths have occurred. ■ Use caution in patients with hepatic impairment. ■ See Monitor and Drug/Lab Interactions.

Monitor:

Obtain baseline CBC, differential, platelets, and liver function tests. ■ Monitor CBC, differential, and platelets before each dose. Neutropenia is dose-limiting. Neutropenia nadirs occur between 7 and 10 days after the dose, and recovery should occur within the following 7 to 14 days; see Dose Adjustments. ■ Monitor hepatic function periodically during treatment; see Dose Adjustments. ■ Monitor for S/S of constipation/ileus (e.g., abdominal pain, bowel movements, bowel sounds). ■ Promptly evaluate patients with alterations in their baseline pulmonary functions or with new onset of cough, dyspnea, hypoxia, or other symptoms. Onset of pulmonary toxicity has occurred in 3 to 8 days. ■ Monitor for new or worsening S/S of neuropathy (e.g., hyperesthesia, hyporeflexia, muscle weakness, paresthesia). ■ Determine absolute patency and quality of vein and adequate circulation of extremity; see Antidote. ■ Be alert for any sign of infection. Infections must be brought under control before beginning therapy with vinorelbine. ■ Use of prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Maintain adequate hydration. ■ Prophylactic antiemetics may increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Report burning or stinging at IV site promptly. ■ Report chills, fever, difficulty breathing, or shortness of breath promptly. ■ Avoid pregnancy. Females of reproductive potential should use highly effective contraception during therapy and for 6 months after the final dose. Males with female sexual partners of reproductive potential should use highly effective contraception during and for 3 months after therapy. ■ May damage spermatozoa and decrease fertility in male patients. ■ Follow a diet rich in fiber, drink fluids liberally to stay hydrated, and use stool softeners to avoid constipation. ■ Report new or worsening numbness, tingling or decreased sensation, or muscle weakness. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy; based on its mechanism of action, vinorelbine can cause fetal harm. ■ Discontinue breast-feeding during treatment and for 9 days after the final dose. ■ Safety and effectiveness for use in pediatric patients have not been established but have been investigated. In one study, vinorelbine was considered to be ineffective when used in doses similar to those used in adults in a limited number of pediatric patients with recurrent solid malignant tumors (e.g., rhabdomyosarcoma/undifferentiated sarcoma, neuroblastoma, and CNS tumors). Toxicities were similar to those reported in adults.

Elderly:

No overall difference in safety, efficacy, and pharmacokinetic parameters have been observed between the elderly and younger adult patients.

DRUG/LAB INTERACTIONS

Drugs that inhibit the cytochrome P_{450} isoenzymes in the CYP3A subfamily (e.g., azole antifungals and macrolides) may inhibit the metabolism of vinorelbine and increase its toxicity. ■ Neurotoxicity may be increased by **other neurotoxic drugs** (e.g., antineoplastics [such as cisplatin, paclitaxel]); may require discontinuation of vinorelbine. Vestibular and auditory deficits have been observed, usually when vinorelbine is used in combination with cisplatin. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ **Mitomycin-C** may cause or aggravate acute pulmonary reactions (e.g., acute shortness of breath, bronchospasm). ■ Neutropenia is significantly higher when used in combination with **cisplatin.** ■ Additive bone marrow suppression may occur with **radiation therapy and/or other bone marrow–suppressing agents** (e.g., azathioprine, chloramphenicol, melphalan); dose reductions may be required.

SIDE EFFECTS

Neutropenia is the major dose-limiting toxicity and may be significantly greater in combination regimens. Other commonly reported adverse reactions are anemia, asthenia, constipation, injection site reactions, leukopenia, liver enzyme elevation (AST and bilirubin), nausea, peripheral neuropathy, and vomiting. Additional adverse reactions occurring in at least 5% of patients receiving vinorelbine as a single agent include alopecia, chest pain, diarrhea, dyspnea, phlebitis, and thrombocytopenia. When used in combination with cisplatin, adverse reactions reported in at least 10% of patients included alopecia, arthralgia, constipation, decreased appetite, decreased weight, diarrhea, embolism, fatigue, fever, hematologic toxicity (anemia, leukopenia, neutropenia, febrile neutropenia, thrombocytopenia), impaired hearing, increased SCr, infection, injection site reactions, lethargy, malaise, myalgia, nausea, ototoxicity, paresthesia, peripheral numbness, phlebitis, taste alterations, thrombosis, vomiting, and weakness.

Post-Marketing:

Abdominal pain, anaphylactic reaction, angioedema, back pain, blistering, deep venous thrombosis, dermatitis, dysphagia, electrolyte imbalance (including hyponatremia), esophagitis, flushing, gait disturbance, headache, hypertension, hypotension, jaw pain, loss of tendon reflex, mucosal inflammation, muscular weakness, palmar-plantar erythrodysesthesia syndrome, pancreatitis, pneumonia, pruritus, pulmonary edema, pulmonary embolism, radiation recall phenomenon, rash, sloughing of skin, tachycardia, tumor pain, urticaria, vasodilation, vestibular disorder.

ANTIDOTE

Notify the physician of all side effects; symptomatic treatment is often indicated. For severe reactions, discontinue vinorelbine or reduce subsequent doses. Discontinue vinorelbine for development of Grade 2 or greater neurotoxicity, interstitial pneumonitis, or ARDS. See Dose Adjustments. For extravasation, discontinue the drug immediately and administer into another vein. Institute recommended management measures based on institutional policies. Elevation of the extremity, application of dry heat, and hyaluronidase administration have been used for treatment of extravasation. Bone marrow toxicity is reversible after discontinuing vinorelbine. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) may be indicated. Darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, or sargramostim may be used to promote bone marrow recovery but may not be given within 24 hours of a dose of cytotoxic therapy or until 24 hours after a dose of cytotoxic therapy.

VON WILLEBRAND FACTOR/COAGULATION FACTOR VIII COMPLEX (HUMAN)

(von **WILL**-a-brand **FAK**-tor/koh-**AG**-yoo-**LAY**-shun **FAK**-tor VIII **KOM**-plex) (**HYOO**-man)
Wilate
Antihemorrhagic

USUAL DOSE (International units [IU])

Pretreatment:

Prophylactic vaccinations recommended; see Patient Education.

One IU of von Willebrand factor:Ristocetin Cofactor (VWF:RCo) is approximately equal to the level of VWF:RCo activity found in 1 mL of fresh human plasma. The ratio between VWF:RCo and FVIII activities in Wilate is approximately 1:1. When using a FVIII-containing VWF product, continued treatment may cause an excessive rise in

FVIII activity; see Monitor.

Calculate the required dose using the following formula:

$$\text{Required IU} = \text{Body weight (kg)} \times \text{Desired VWF:RCo rise (\%) (IU/dL)} \times 0.5\ \text{(IU/kg per IU/dL)}$$

Adjust dose and frequency of administration according to the clinical effectiveness in each patient. The following chart provides estimated doses for minor and major hemorrhages.

Guide to Wilate Dosing for Treatment of Minor and Major Hemorrhages

Type of Hemorrhage	Loading Dose (IU VWF:RCo/kg)	Maintenance Dose (IU VWF:RCo/kg)	Therapeutic Goal
Minor Hemorrhages	20 to 40 IU/kg	20 to 30 IU/kg every 12 to 24 hours[a]	VWF:RCo and FVIII activity trough levels of >30%
Major Hemorrhages	40 to 60 IU/kg	20 to 40 IU/kg every 12 to 24 hours[a]	VWF:RCo and FVIII activity trough levels of >50%

[a] Maintenance doses may need to be continued for up to 3 days for minor hemorrhages and 5 to 7 days for major hemorrhages. Repeat doses may be administered for as long as needed based on repeated monitoring of appropriate clinical and laboratory measures.

Recommendations for dosing in minor and major surgeries is provided in the following chart.

Guide to Wilate Dosing for Treatment in Minor and Major Surgeries in All vWD[a] Types

Type of Surgery	Loading Dose (IU VWF: RCo/kg) (Within 3 Hours Before Surgery)	VWF:RCo Peak Levels (% of Normal)	Maintenance Dose (IU VWF: RCo/kg)	VWF:RCo Trough Levels (% of Normal)	Frequency of Doses (hours)	Duration of Therapy (days)
Minor (including tooth extraction)	30 to 60 IU/kg	50%	15 to 30 IU/kg or half the loading dose	Greater than 30%	12 to 24 hours	Until wound healing achieved, up to 3 days
Major	40 to 60 IU/kg	100%	20 to 40 IU/kg or half the loading dose	Greater than 50%	12 to 24 hours (at least 2 doses within the first 24 hours after the start of surgery)	Until wound healing achieved, up to 6 days or more

[a] vWD, von Willebrand disease.

See prescribing information for an alternate formula to determine loading dose based on patient's individual in vivo recovery (IVR) determined before surgery.

Performing appropriate lab tests once a day after surgery is recommended to ensure adequate VWF:RCo and FVIII activity levels are reached and maintained. To decrease the risk of perioperative thrombosis, FVIII activity levels should not exceed 250%.

PEDIATRIC DOSE

Follow the general recommendations for dosing and administration for adults. See Usual Dose and Maternal/Child.

DOSE ADJUSTMENTS

Adjust dose according to the extent and location of bleeding and the patient's clinical condition. ■ vWD Type 3 patients with GI bleeding may require higher doses.

DILUTION (International units [IU])

Available in 5-mL and 10-mL vials containing either 500 or 1,000 IU VWF:RCo and 500 or 1,000 IU FVIII activities. Provided as a kit containing a single-dose vial of powder, a vial of diluent, a Mix2Vial transfer device, a 10-mL syringe, an infusion set, and 2 alcohol swabs. Consult instructions for reconstitution and injection in the package insert. Warm to room temperature (25° C) before dilution and maintain throughout reconstitution. If a water bath is used for warming (temperature should not exceed 37° C [98° F]), do not allow water to come into contact with the latex-free rubber stopper or vial caps. The total number of IUs available is clearly marked on each vial. Record the batch number of each vial. Should be used immediately after reconstitution. Solution should be clear or slightly opalescent.

Filters:

Incorporated into the Mix2Vial.

Storage:

Store in original carton to protect from light. Stable for 36 months from date of manufacture when refrigerated at 2° to 8° C (36° to 46° F). Do not freeze. May be stored at RT (maximum of 25° C [77° F]) for up to 6 months. Label vial with date removed from refrigeration. Once stored at RT, do not return to refrigeration. Shelf life expires 6 months from date of removal from refrigeration or on the expiration date on the product vial, whichever is earlier. Administer immediately after reconstitution. Discard any unused solution.

COMPATIBILITY

Manufacturer states, "Must not be mixed with other medicinal products or administered simultaneously with other IV preparations in the same infusion set."

RATE OF ADMINISTRATION

A single dose as an infusion at 2 to 4 mL/min. Reduce rate of administration or interrupt the infusion if a marked increase in pulse occurs.

ACTIONS

A purified, lyophilized von Willebrand factor (VWF) and coagulation factor VIII complex that is obtained from pooled human plasma. VWF and FVIII are normal constituents of human plasma. Patients with vWD have a deficiency or abnormality of VWF; this results in low FVIII activity and an abnormal platelet function, which causes excessive bleeding. VWF promotes platelet aggregation and platelet adhesion on damaged vascular endothelium; it also serves as a stabilizing carrier protein for the procoagulant protein FVIII, an essential cofactor in the activation of factor X, leading to the formation of thrombin and fibrin. VWF activity is measured with an assay that uses an agglutinating cofactor called Ristocetin (RCo). The VWF:RCo assay provides a quantitative measurement of VWF function by determining how well VWF helps platelets adhere to one another. Reduced VWF:RCo activity indicates a deficiency of VWF. Half-life varies based on type of vWD (1, 2, or 3).

INDICATIONS AND USES

On-demand treatment and control of bleeding episodes and perioperative management of bleeding in pediatric patients and adults with von Willebrand disease.

Limitation of use:

Not indicated for the treatment of hemophilia A.

CONTRAINDICATIONS

History of anaphylactic or severe systemic reactions to plasma-derived products, any ingredient in the formulation, or components of the container.

PRECAUTIONS

For IV use only. ■ Administered under the direction of a physician knowledgeable in the treatment of coagulation disorders in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, have occurred; see Monitor. ■ Manufactured from human plasma. Risk of transmitting infectious agents (e.g., HIV, hepatitis and, theoretically, Creutzfeldt-Jakob disease) has been greatly reduced by screening, testing, and manufacturing techniques. However, risk of transmission cannot be totally eliminated. ■ Hepatitis A and B vaccines are recommended for patients receiving plasma derivatives. ■ Thrombotic events have been reported. Use caution in patients with known risk factors for thrombosis. ■ Inhibitors may develop with large or frequent doses; see Monitor.

Monitor:

Monitor BP and pulse during infusion. If a marked increase in pulse occurs, either reduce rate of infusion or interrupt the infusion. ■ Throughout the infusion, monitor for S/S of a hypersensitivity reaction (e.g., angioedema, burning and stinging at injection site, chills, fever, flushing, headache, hives, hypotension, nausea, tachycardia, tightness of the chest, urticaria, vomiting, wheezing). Evaluate for the presence of inhibitors if an anaphylactic reaction occurs. ■ Appropriate laboratory tests should be performed on the patient's plasma at suitable intervals to ensure that adequate VWF:RCo and FVIII activity levels have been reached and are maintained. Monitoring is also required to avoid sustained excessive VWF and FVIII activity. When using a VWF product that contains FVIII, continued treatment may cause an excessive rise in FVIII activity. Excessive activity levels may increase the risk of thrombotic events. In the postsurgery period, monitoring should be done daily if possible, and FVIII levels should not exceed 250%. ■ Monitor for development of VWF and FVIII inhibitors (neutralizing antibodies). Consider formation of inhibitors and perform assays if bleeding is not controlled with usual doses.

Patient Education:

Review manufacturer's medication guide. ■ Prophylactic hepatitis A and hepatitis B vaccines recommended. ■ Promptly report S/S of a hypersensitivity reaction (e.g., dizziness, hives, itching, rash, tightness of the chest). ■ Frequent blood tests (e.g., monitoring of VWF:RCo and FVIII activity) are required to ensure effectiveness and reduce the risk of thrombotic events. ■ Inhibitors may develop if expected VWF activity plasma levels are not attained or if bleeding is not controlled with adequate or repeat dosing; notify treating physician. ■ Report symptoms of possibly transmitted viral infections immediately. Symptoms may include anorexia, arthralgias, fatigue, jaundice, low-grade fever, nausea, or vomiting.

Maternal/Child:

Use during pregnancy or labor and delivery only if clearly needed. ■ Safety for use during breast-feeding is unknown; consider benefit versus risk. ■ Approved for use in pediatric patients. No dose adjustment is required.

Elderly:

Numbers insufficient to determine differences in response compared with younger adults.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

The most common side effects reported are dizziness, hypersensitivity reactions, and urticaria. The most serious adverse reactions were hypersensitivity reactions.

Post-Marketing:

Abdominal pain, anaphylactic reaction, chest discomfort, chills, cough, dyspnea, factor VIII inhibition, fever, flushing, headache, hypotension, nausea, paresthesia, rash, tachycardia, and vomiting.

ANTIDOTE

Keep the physician informed of side effects. Slow or interrupt infusion for a marked increase in pulse rate or mild hypersensitivity reaction. Discontinue the infusion immediately if a severe hypersensitivity reaction or thrombotic event (e.g., chest pain, dyspnea, leg pain, MI) occurs, and evaluate for the presence of inhibitors. Treat hypersensitivity as necessary (e.g., antihistamines, epinephrine, corticosteroids), and treat thrombotic events with appropriate measures. Resuscitate as necessary.

VON WILLEBRAND FACTOR (RECOMBINANT)

(von **WILL**-a-brand **FAK**-tor)
Vonvendi
Antihemorrhagic

USUAL DOSE (International units [IU])

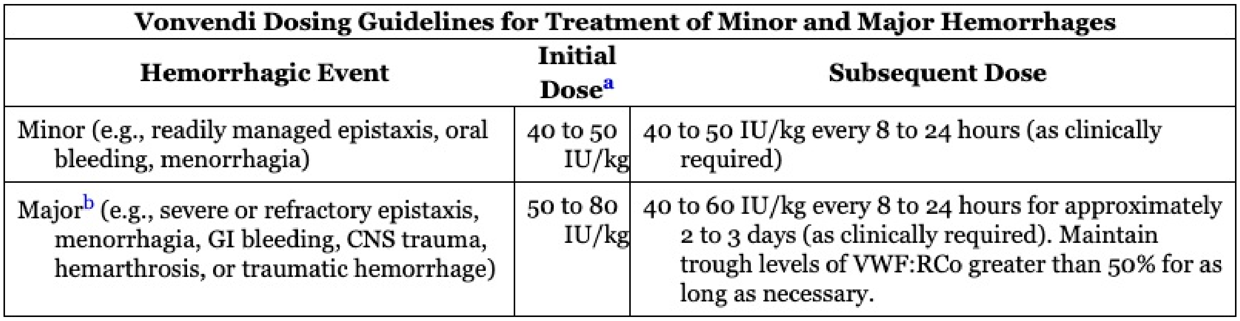
Each vial is labeled with the actual amount of recombinant von Willebrand factor (rVWF) activity in international units (IU) as measured with the Ristocetin cofactor assay (VWF:RCo). Hemostasis cannot be ensured until factor VIII coagulation activity (FVIII:C) level reaches 0.4 IU/mL (40% of normal activity).

If the patient's baseline plasma FVIII:C level is below 40% or unknown, it is necessary to administer an approved recombinant, non–VWF-containing factor VIII (e.g., Advate) with the first infusion of recombinant von Willebrand factor (rVWF) in order to achieve a hemostatic plasma level of FVIII:C.

If an immediate rise in FVIII:C is not necessary or if the baseline FVIII:C level is sufficient to ensure hemostasis, recombinant von Willebrand factor (rVWF) may be administered without recombinant factor VIII.

Initial dose:

40 to 80 IU/kg. For each bleeding episode, administer an approved recombinant, non–VWF-containing factor VIII (e.g., Advate) within 10 minutes of the initial dose of rVWF if factor VIII baseline levels are below 40% or unknown. A ratio of 1.3:1 (30% more) VWF to factor VIII is recommended. The following chart provides estimated doses for minor and major hemorrhages.



Vonvendi Dosing Guidelines for Treatment of Minor and Major Hemorrhages

Hemorrhagic Event	Initial Dose[a]	Subsequent Dose
Minor (e.g., readily managed epistaxis, oral bleeding, menorrhagia)	40 to 50 IU/kg	40 to 50 IU/kg every 8 to 24 hours (as clinically required)
Major[b] (e.g., severe or refractory epistaxis, menorrhagia, GI bleeding, CNS trauma, hemarthrosis, or traumatic hemorrhage)	50 to 80 IU/kg	40 to 60 IU/kg every 8 to 24 hours for approximately 2 to 3 days (as clinically required). Maintain trough levels of VWF:RCo greater than 50% for as long as necessary.

[a] If recombinant factor VIII is administered, see its package insert for reconstitution and administration instructions.

[b] A bleed can be considered major if RBC transfusion is either required or potentially indicated or if bleeding occurs in a critical anatomic site (e.g., intracranial or GI

hemorrhage).

The initial dose of rVWF should achieve greater than 60% VWF levels (based on VWF:RCo greater than 0.6 IU/mL), and an infusion of recombinant factor VIII should achieve factor VIII levels greater than 40% (FVIII:C greater than 0.4 IU/mL). To calculate specific doses using the correct ratio of 1.3:1, the following formula is recommended:

$$\text{Vonvendi dose (IU)} = \text{Dose in (IU/kg)} \times \text{Weight (kg)}$$

$$\text{Recombinant factor VIII dose (IU)} = \text{Vonvendi dose} \div 1.3$$

DOSE ADJUSTMENTS

Adjust dose according to the extent and location of bleeding. ■ Administer subsequent doses as long as clinically required.

DILUTION (International units [IU])

Provided as a kit containing a single-dose vial of powder, a vial of diluent, and a Mix2Vial reconstitution device. Consult instructions for reconstitution and administration in the package insert. Use of plastic syringes is recommended. Warm to room temperature (25° C) before dilution and maintain throughout reconstitution. The total number of IUs available is clearly marked on each vial (approximately 650 or 1,300 IU of VWF:RCo). Record the batch number of each vial. Should be used immediately after reconstitution. Solution should be clear or slightly opalescent. Use a new Mix2Vial transfer set and syringe for each vial of drug.

If more than one vial is required, the contents of each vial must be drawn into individual syringes that should be left attached to the vial until ready to infuse to reduce the risk of contamination.

Filters:

Incorporated into the Mix2Vial.

Storage:

Store refrigerated at 2° to 8° C (36° to 46° F) in original carton to protect from light. Do not freeze. May be stored at RT (maximum of 30° C [86° F]) for up to 12 months. Label vial with date removed from refrigeration. Once stored at RT, do not return to refrigeration. Do not use beyond the expiration date on the product vial. Administer immediately after reconstitution, or store at RT not to exceed 27° C (81° F) for up to 3 hours. Do not refrigerate after reconstitution. Discard after 3 hours.

COMPATIBILITY

Manufacturer states, “Do not mix with other medicinal products. Use plastic syringes; proteins in the product tend to stick to the surface of glass syringes.”

RATE OF ADMINISTRATION

A single dose may be administered as an infusion up to a maximum rate of 4 mL/min;

consider patient comfort. Reduce rate of administration or interrupt the infusion if an increase in heart rate occurs.

ACTIONS

A purified, recombinant von Willebrand factor (rVWF) expressed in Chinese hamster ovary (CHO) cells. Patients with von Willebrand disease (vWD) have a deficiency or abnormality of VWF; this results in low factor VIII activity and an abnormal platelet function, which causes excessive bleeding. VWF re-establishes platelet adhesion at the site of vascular damage, providing primary hemostasis (shortening of bleeding time occurs immediately), and it stabilizes factor VIII by binding to it and preventing its rapid degradation. This latter action is slightly delayed. VWF activity is measured with an assay that uses an agglutinating cofactor called Ristocetin (RCo). The VWF:RCo assay provides a quantitative measurement of VWF function by determining how well VWF helps platelets adhere to one another. Reduced VWF:RCo activity indicates a deficiency of VWF. A sustained increase of factor VIII coagulation activity (FVIII:C) was observed 6 hours after a single infusion of rVWF. Half-life ranged from 19.1 to 21.9 hours depending on the dose administered.

INDICATIONS AND USES

On-demand treatment and control of bleeding episodes in adults (age 18 and older) diagnosed with von Willebrand disease.

CONTRAINDICATIONS

Life-threatening hypersensitivity reactions to von Willebrand factor (recombinant) or constituents of the product or to hamster or mouse proteins.

PRECAUTIONS

For IV use only. ■ Administered under the direction of a physician knowledgeable in the treatment of coagulation disorders in a facility with adequate diagnostic and treatment facilities to monitor patient and respond to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, have occurred; see Monitor. ■ Thrombotic events, including disseminated intravascular coagulation (DIC), venous thrombosis, pulmonary embolism, MI, and stroke, can occur, particularly in patients with known risk factors for thrombosis. ■ Neutralizing antibodies (inhibitors) to VWF and/or factor VIII can occur; see Monitor.

Monitor:

Monitor BP and heart rate during infusion. If an increase in heart rate occurs, either reduce rate of infusion or interrupt the infusion. ■ Throughout the infusion, monitor for S/S of a hypersensitivity reaction (e.g., acute respiratory distress, angioedema, chest tightness, hypotension, lethargy, nausea, paresthesia, pruritus, restlessness, urticaria, vomiting, wheezing). ■ Appropriate laboratory tests should be performed on the patient's plasma at suitable intervals. If expected VWF activity plasma levels are not attained or if bleeding episode is not controlled with an appropriate dose, perform an assay that measures the presence of VWF or factor VIII inhibitors. ■ Monitor plasma levels of VWF:RCo and factor VIII activities to avoid sustained excessive VWF and/or factor VIII activity levels, which may increase the risk of thrombotic events. ■ Monitor for early S/S of thrombotic events such as cough, discoloration, dyspnea, hemoptysis, pain, swelling, and syncope.

Patient Education:

Review manufacturer's medication guide. ■ Promptly report S/S of a hypersensitivity reaction (e.g., dizziness, hives, itching, rash, tightness of the chest). ■ Frequent blood tests (e.g., monitoring of VWF:RCo and FVIII activity) are required to reduce the risk of thrombotic events. ■ Report a lack of clinical response to therapy; may be a manifestation of an inhibitor. ■ If traveling, bring an adequate supply of medication based on current treatment regimen.

Maternal/Child:

Use during pregnancy or labor and delivery only if clearly needed. ■ Safety for use during breast-feeding not known; consider benefit versus risk. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly:

Numbers insufficient to determine differences in response compared with younger adults.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

The most common side effect is generalized pruritus. Chest discomfort, dizziness, dysgeusia, hot flush, hypertension, infusion site paresthesia, nausea, tachycardia, and tremor have occurred.

ANTIDOTE

Keep the physician informed of side effects. Slow or interrupt infusion for an increase in heart rate or mild hypersensitivity reaction. Discontinue the infusion immediately if a severe hypersensitivity reaction or thrombotic event (e.g., chest pain, dyspnea, leg pain, MI) occurs. Treat hypersensitivity as necessary (e.g., antihistamines, epinephrine, corticosteroids), and treat thrombotic events with appropriate measures. Resuscitate as necessary.

VORICONAZOLE

(**vor**-ih-**KOH**-nah-zohl)
VFEND IV
Antifungal
(azole derivative)

USUAL DOSE

Pretreatment:

Verify pregnancy status. Pretesting required; see Precautions and Monitor. Obtain baseline electrolytes and correct calcium, magnesium, and potassium deficiencies before initiating voriconazole.

Duration of treatment is based on severity of the underlying disease, recovery from immunosuppression, and clinical response.

Voriconazole Dose Guidelines in Adults			
Infection	**Loading Dose**	**IV Maintenance Dose[a]**	**Oral Maintenance Dose[a]**
Invasive aspergillosis[b,c]	6 mg/kg q 12 hr for the first 24 hours	4 mg/kg q 12 hr	200 mg q 12 hr[d]
Candidemia in nonneutropenic patients and in other deep tissue *Candida* infections	6 mg/kg q 12 hr for the first 24 hours	3 to 4 mg/kg q 12 hr[e,f]	200 mg q 12 hr[d,e,f]
Esophageal candidiasis			200 mg q 12 hr[d,g]
Scedosporiosis and fusariosis[c]	6 mg/kg q 12 hr for the first 24 hours	4 mg/kg q 12 hr	200 mg q 12 hr[d]

[a] In healthy volunteer studies, a 200-mg oral dose every 12 hours provided an exposure (AUC) similar to a 3-mg/kg IV dose every 12 hours; a 300-mg oral dose every 12 hours provided an exposure (AUC) similar to a 4-mg/kg IV dose every 12 hours.

[b] In a clinical study of invasive aspergillosis, the median duration of IV voriconazole was 10 days (range 2 to 85 days). Median duration of oral therapy was 76 days (range 2 to 232 days).

[c] IV therapy should be continued for at least 7 days.

[d] Patients who weigh 40 kg or more should receive an oral maintenance dose of 200 mg q 12 hr. Adult patients who weigh less than 40 kg should receive an oral maintenance dose of 100 mg q 12 hr.

[e] In clinical trials, patients with candidemia received 3 mg/kg q 12 hr as primary therapy, and patients with other deep tissue *Candida* infections received 4 mg/kg as salvage therapy. Appropriate dose should be based on the severity and nature of the infection.

[f] Treat for at least 14 days following resolution of symptoms or following last positive culture, whichever is longer.

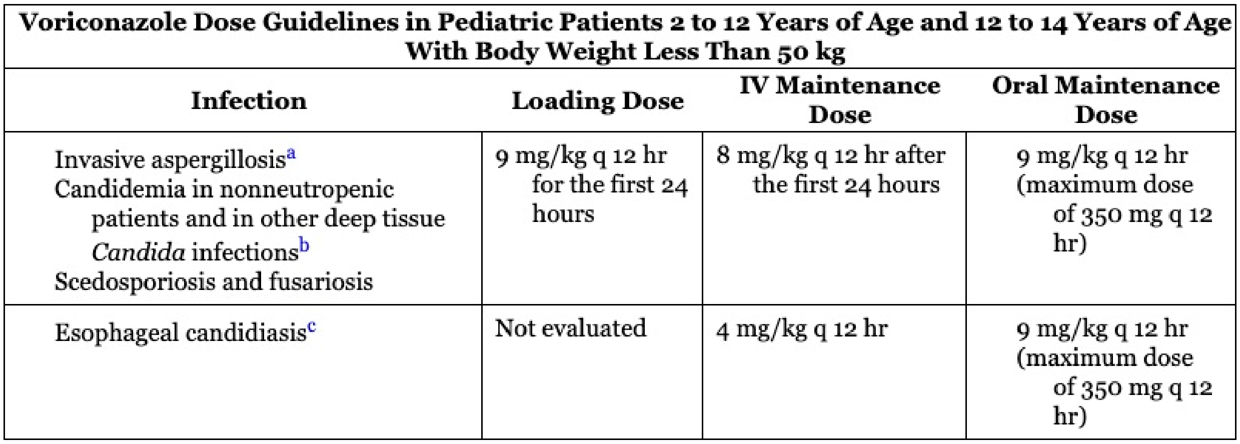
[g] Treat for a minimum of 14 days and for at least 7 days following the resolution of symptoms.

For all indications:

A switch between IV and oral formulations is appropriate because of high bioavailability of oral formulations. Depending on diagnosis, may switch to oral formulation when a patient has shown clinical improvement and can tolerate oral therapy; see Patient Education.

PEDIATRIC DOSE

Initiate therapy with an IV infusion regimen. Consider an oral regimen only after there is a significant clinical improvement. Note that an 8 mg/kg IV dose will provide voriconazole exposure approximately twofold higher than a 9 mg/kg oral dose. Oral bioavailability may be limited in pediatric patients 2 to 12 years of age with malabsorption and very low body weight for age. IV voriconazole administration is recommended.



Voriconazole Dose Guidelines in Pediatric Patients 2 to 12 Years of Age and 12 to 14 Years of Age With Body Weight Less Than 50 kg

Infection	Loading Dose	IV Maintenance Dose	Oral Maintenance Dose
Invasive aspergillosis[a] Candidemia in nonneutropenic patients and in other deep tissue *Candida* infections[b] Scedosporiosis and fusariosis	9 mg/kg q 12 hr for the first 24 hours	8 mg/kg q 12 hr after the first 24 hours	9 mg/kg q 12 hr (maximum dose of 350 mg q 12 hr)
Esophageal candidiasis[c]	Not evaluated	4 mg/kg q 12 hr	9 mg/kg q 12 hr (maximum dose of 350 mg q 12 hr)

[a] Based on a population pharmacokinetic analysis in 112 immunocompromised pediatric patients 2 years to less than 12 years of age and 26 immunocompromised pediatric patients 12 years to less than 17 years of age.

[b] In the phase 3 clinical trials, patients with invasive aspergillosis (IA) received IV treatment for at least 6 weeks and up to a maximum of 12 weeks. Patients received IV treatment for at least the first 7 days of therapy and then could be switched to oral therapy.

[c] Study treatment for primary or salvage invasive candidiasis and candidemia (ICC) or EC consisted of IV voriconazole, with an option to switch to oral therapy after at least 5 days of IV therapy based on subjects meeting switch criteria. For subjects with primary or salvage ICC, voriconazole was administered for at least 14 days after the last positive culture. A maximum of 42 days of treatment was permitted. Patients with primary or salvage EC were treated for at least 7 days after the resolution of clinical signs and symptoms. A maximum of 42 days of treatment was permitted.

DOSE ADJUSTMENTS

Adult patients with an inadequate response weighing 40 kg or more:

Increase the oral maintenance dose from 200 mg every 12 hours (similar to 3 mg/kg IV every 12 hours) to 300 mg every 12 hours (similar to 4 mg/kg every 12 hours). If unable to tolerate the 300-mg oral dose, decrease it by 50-mg increments to a minimum of 200 mg orally every 12 hours.

Adult patients with an inadequate response weighing less than 40 kg:

Increase the oral maintenance dose from 100 mg every 12 hours to 150 mg every 12 hours. If unable to tolerate the 150-mg dose, decrease it to 100 mg orally every 12 hours. ■ Reduce the IV maintenance dose to 3 mg/kg every 12 hours in patients unable to tolerate treatment. ■ If phenytoin is being administered concurrently, increase the IV maintenance dose of voriconazole to 5 mg/kg every 12 hours or from 200 to 400 mg orally every 12 hours (or 100 mg to 200 mg orally every 12 hours in patients weighing less than 40 kg); see Drug/Lab Interactions. ■ When voriconazole is coadministered with efavirenz (Sustiva), increase voriconazole oral maintenance dose to 400 mg every 12 hours and decrease efavirenz dose to 300 mg every 24 hours. ■ No dose adjustment is indicated based on age or gender or in patients with baseline liver function tests (ALT, AST) up to 5 times the ULN (see Precautions and Monitor). ■ In patients with mild to moderate hepatic cirrhosis (Child-Pugh Class A and B), use the standard loading dose but reduce the maintenance dose by one-half. ■ No dose adjustment is required in patients with a CrCl of 50 mL/min or greater; however, the intravenous vehicle, sulfobutyl ether beta-cyclodextrin sodium (SBECD), accumulates in patients with a CrCl of less than 50 mL/min. Use of oral voriconazole is recommended in these patients; see Precautions and Monitor. ■ A 4-hour hemodialysis session does not remove a sufficient amount of voriconazole to warrant dose adjustment.

Pediatric patients 2 to 12 years of age and 12 to 14 years of age weighing less than 50 kg:

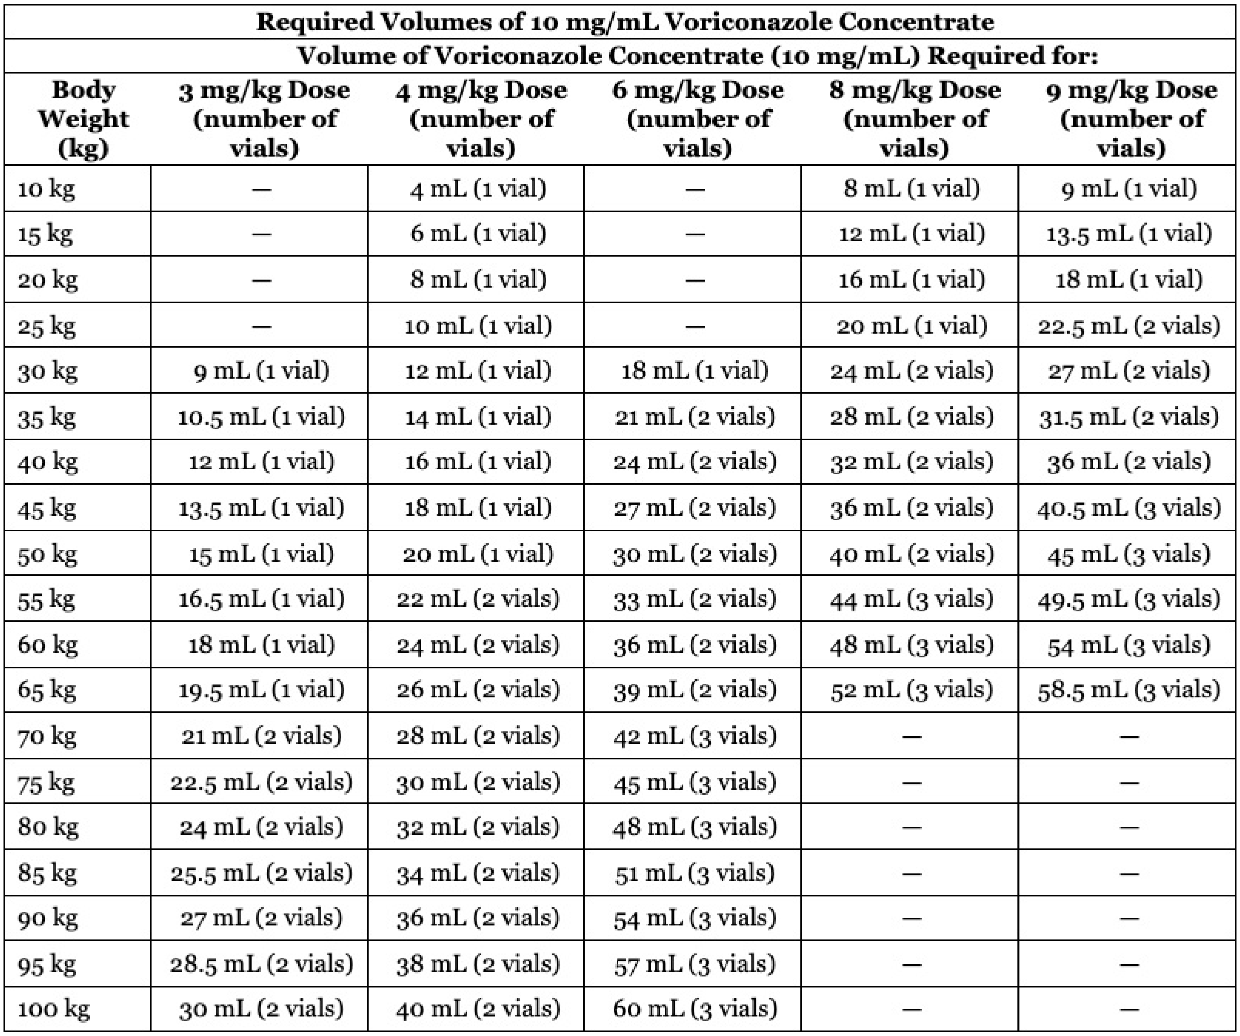
If patient response is inadequate and the patient is able to tolerate the initial IV maintenance dose, the maintenance dose may be increased by 1 mg/kg steps. ■ If patient response is inadequate and the patient is able to tolerate the oral maintenance dose, the dose may be increased by 1 mg/kg steps or 50 mg steps to a maximum of 350 mg every 12 hours. ■ If patient is unable to tolerate the initial IV maintenance dose, reduce the dose by 1 mg/kg steps. ■ If patient is unable to tolerate the oral maintenance dose, reduce the dose by 1 mg/kg or 50 mg steps.

Pediatric patients 12 to 14 years of age weighing 50 kg or more and pediatric patients 15 years of age and older regardless of body weight:

Use the optimal method for titrating dose recommended for adults.

DILUTION

Reconstitute each vial with exactly 19 mL SWFI. Use of a standard 20-mL (nonautomated) syringe is recommended to facilitate exact measurement. Volume will be 20 mL (10 mg/mL). Discard the vial if a vacuum is not present to pull the diluent into the vial. Shake until all powder is dissolved. Calculate the required dose based on patient weight (see the following chart). Must be further diluted for infusion in D5W, D5LR, LR, NS, D5/½NS, D5NS, ½NS, or D5W with 20 mEq KCl. Withdraw a volume equal to the calculated dose of voriconazole from an infusion bag or bottle (30 mL in the following example). The volume of diluent left in the infusion bag or bottle should be enough to allow a final concentration of not less than 0.5 mg/mL or greater than 5 mg/mL after voriconazole is added. Withdraw the required volume of reconstituted drug and add to the infusion bag or bottle. For example, a patient weighing 50 kg will require a loading dose of 300 mg (6 mg/kg × 50 kg), which equals 30 mL of reconstituted drug (1½ vials). Withdraw and discard 30 mL of solution from a 100-mL infusion bag and add the 30 mL of reconstituted drug. Final concentration equals 3 mg/mL.



Required Volumes of 10 mg/mL Voriconazole Concentrate					
	Volume of Voriconazole Concentrate (10 mg/mL) Required for:				
Body Weight (kg)	**3 mg/kg Dose (number of vials)**	**4 mg/kg Dose (number of vials)**	**6 mg/kg Dose (number of vials)**	**8 mg/kg Dose (number of vials)**	**9 mg/kg Dose (number of vials)**
10 kg	—	4 mL (1 vial)	—	8 mL (1 vial)	9 mL (1 vial)
15 kg	—	6 mL (1 vial)	—	12 mL (1 vial)	13.5 mL (1 vial)
20 kg	—	8 mL (1 vial)	—	16 mL (1 vial)	18 mL (1 vial)

95 kg	28.5 mL (2 vials)	38 mL (2 vials)	57 mL (3 vials)	—	—
100 kg	30 mL (2 vials)	40 mL (2 vials)	60 mL (3 vials)	—	—

Filters:

No data available from manufacturer.

Storage:

Store unopened vials at CRT. Immediate use of reconstituted vials is preferred; however, they may be refrigerated up to 24 hours at 2° to 8° C (37° to 46° F). Discard partially used vials.

COMPATIBILITY

Must not be infused concomitantly with any blood product or short-term infusion of concentrated electrolytes, even if the two infusions are running in separate IV lines or cannulas. Electrolyte disturbances such as hypokalemia, hypomagnesemia, and hypocalcemia should be corrected before initiation of voriconazole; see Precautions. Voriconazole can be infused at the same time as other IV solutions containing (nonconcentrated) electrolytes but must be infused through a separate line. Voriconazole can be infused at the same time as total parenteral nutrition (TPN) but must be infused in a separate line. If infused through a multiple-lumen catheter, TPN needs to be administered using a different port from the one used for voriconazole. Manufacturer states that voriconazole should not be diluted with 4.2% sodium bicarbonate solution. **Compatibility** with other concentrations of sodium bicarbonate is unknown; do not use.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion ***over 1 to 2 hours***. Do not exceed a rate of 3 mg/kg/hr.

ACTIONS

A triazole antifungal agent. Inhibits a fungal cytochrome P_{450}-mediated essential step in fungal ergosterol biosynthesis. With a loading dose regimen, peak and trough plasma concentrations close to steady-state concentrations are achieved within the first 24 hours. Extensively distributed into tissues. Plasma protein binding (estimated at 58%) is not affected by varying degrees of hepatic and renal insufficiency. Metabolized by cytochrome P_{450} enzymes (CYP2C19 is significantly involved). Terminal half-life is dose dependent and is not useful in predicting accumulation or elimination. Eliminated via hepatic metabolism; less than 2% is excreted unchanged in urine.

INDICATIONS AND USES

For use in patients 2 years of age and older in treatment of the following infections: Treatment of invasive aspergillosis caused by *Aspergillus fumigatus* and other species of *Aspergillus*. ■ Treatment of candidemia in nonneutropenic patients and the following *Candida* infections: disseminated infections in the skin and infections in the abdomen, kidney, bladder wall, and wounds. ■ Treatment of serious fungal infections caused by *Scedosporium apiospermum* and *Fusarium* species, including *Fusarium solani,* in patients intolerant of or refractory to other therapy. ■ Treatment of esophageal candidiasis.

CONTRAINDICATIONS

Hypersensitivity to voriconazole or any of its components. Use caution in patients exhibiting hypersensitivity to other azole antifungals (e.g., fluconazole, itraconazole, ketoconazole); see Precautions. ■ Coadministration is specifically **contraindicated** with CYP3A4 substrates (e.g., pimozide, quinidine); increased plasma concentrations of these drugs may result in QT prolongation and torsades de pointes. ■ Coadministration is **contraindicated** with the following drugs: barbiturates, carbamazepine, efavirenz (400 mg every 24 hours or higher with a *standard dose* of voriconazole), ergot alkaloids, rifabutin, rifampin, ritonavir, sirolimus, St. John's wort, and tolvaptan; see Drug/Lab Interactions.

PRECAUTIONS

Do not give as an IV bolus; for infusion over 1 to 2 hours only. ■ Specimens for fungal culture, serologic testing, and histopathologic testing should be obtained before therapy to isolate and identify causative organisms. Therapy may begin as soon as all specimens are obtained and before results are known. Reassess after test results are known. ■ Correct electrolyte disturbances such as hypokalemia, hypomagnesemia, and hypocalcemia before initiation of voriconazole. ■ Infusion-related hypersensitivity reactions, including anaphylaxis, chest tightness, dyspnea, faintness, fever, flushing, nausea, pruritus, rash, sweating, and tachycardia have occurred. Usually appear at the beginning of the infusion. If a hypersensitivity reaction occurs, discontinue the infusion. ■ Consider use in patients with severe hepatic insufficiency only if the benefit outweighs potential risk; monitor carefully for drug toxicity. ■ Serious hepatic reactions (including clinical hepatitis, cholestasis, and fulminant hepatic failure, including fatalities) have occurred. Usually occur in patients with serious underlying medical conditions (e.g., hematologic malignancy); however, hepatic reactions, including hepatitis and jaundice, have occurred in patients with no other identifiable risk factors. If liver function tests become markedly elevated compared with baseline, voriconazole should be discontinued unless medical judgment of benefit versus risk justifies continued use. Liver function usually improves with discontinuation of voriconazole. ■ Pancreatitis has been reported; see Monitor. ■ Consider use of IV formulation in patients with a CrCl less than 50 mL/min only if the benefit outweighs potential risk. Accumulation of SBECD may occur with the IV formulation; use of the oral formulation is recommended. ■ Acute renal failure has been reported, usually in patients receiving concomitant nephrotoxic drugs or in patients who have concurrent medical conditions that may result in decreased renal function; see Drug/Lab Interactions. ■ May cause prolongation of the QT interval on ECG and, rarely, torsades de pointes. Use with caution in patients with proarrhythmic conditions (e.g., congenital or acquired QT prolongation, cardiotoxic chemotherapy, cardiomyopathy [in particular when heart failure is present], sinus bradycardia, existing symptomatic arrhythmias, hypokalemia, and concomitant medications that may also prolong the QT interval). ■ Because of the enzymes involved in metabolism, Asian populations may be poor metabolizers, and serum concentrations may be elevated from 2 to 4 times higher than normal metabolizers. Some Whites and Blacks are also poor metabolizers. ■ Blurred vision, color vision changes, and/or photophobia are common but may be associated with higher serum concentrations and/or doses. Usually resolves within 2 weeks of the end of voriconazole therapy. If therapy continues beyond 28 days, the effects of voriconazole therapy on visual function are not known. Prolonged visual adverse effects, including optic neuritis and papilledema, have been reported. ■ Serious exfoliative cutaneous reactions, such as Stevens-Johnson syndrome, have been reported. ■ Photosensitivity skin reactions have been reported. If a phototoxic reaction occurs, the patient should be referred to a dermatologist, and discontinuation should be considered. If therapy is continued despite the occurrence of phototoxicity-related skin lesions, dermatologic evaluation should be performed on a systematic and regular basis to allow for early detection and management of premalignant lesions. Squamous cell carcinoma and melanoma have been reported during long-term therapy. If skin lesions consistent with premalignant skin lesions, squamous cell carcinoma, or melanoma develop, therapy should be discontinued; see Patient Education and Maternal/Child. ■ Fluorosis (mottled enamel of human teeth caused by fluoride) and periostitis (inflammation of the periosteum) have been reported during long-term therapy. Discontinue treatment in patients who develop skeletal pain or radiographic findings consistent with either of these diagnoses. ■ Fungi with reduced susceptibility to one azole antifungal agent may also be less susceptible to other azole derivatives. Cross-resistance may occur and may require alternative antifungal therapy. ■ Oral maintenance doses adjusted based on weight (above or below 40 kg); see product literature.

Monitor:

Obtain baseline electrolytes and make rigorous attempts to correct calcium, magnesium, and potassium before initiating voriconazole. Monitor electrolytes during therapy; may cause hypocalcemia, hypokalemia, and hypomagnesemia. ■ Obtain baseline liver function tests (e.g., alkaline phosphatase, ALT, AST, bilirubin), serum creatinine, and electrolytes in all patients. ■ Monitor liver function tests at least weekly for the first month of treatment. A higher incidence of liver enzyme elevations was observed in pediatric patients. May decrease monitoring to monthly during continued use if no clinically significant changes are noted. ■ Monitor pancreatic function (e.g., serum amylase) in adults and pediatric patients with risk factors for acute pancreatitis (e.g., recent chemotherapy, hematopoietic stem cell transplantation [HSCT]). ■ Monitor serum creatinine during therapy, more frequently in patients with a CrCl less than 50 mL/min. If an increase in serum creatinine occurs, consider changing to the oral formulation. ■ Monitor for S/S of hypersensitivity reactions; see Precautions and Antidote. ■ Monitor visual acuity, visual field, and color perception if treatment continues beyond 28 days. ■ If a rash develops, serious cutaneous reactions (e.g., Stevens-Johnson syndrome) may develop; see Side Effects and monitor closely. Consider discontinuing voriconazole. ■ See Precautions, Drug/Lab Interactions, and Antidote.

Patient Education:

Review of health history and medication profile is imperative. ■ Avoid pregnancy; effective contraception required; see Drug/Lab Interactions. Should pregnancy occur, notify physician immediately and discuss potential hazards. ■ Do not drive at night; changes to vision, including blurring and/or photophobia, may occur. Ophthalmologic monitoring is required with prolonged use. ■ If a change in vision occurs, avoid hazardous tasks, such as driving or operating machinery. ■ Avoid strong, direct sunlight; protective clothing and sunscreen with a high SPF are recommended. ■ Promptly report S/S of a hypersensitivity reaction (e.g., itching, hives, shortness of breath) or a serious skin reaction (e.g., severe sunburn, blistering or peeling of skin). ■

Additional precautions required with transfer to oral voriconazole.

Maternal/Child:

Avoid pregnancy; may cause fetal harm. Teratogenic in rats and embryotoxic in rabbits. Use of effective contraception is required in females of childbearing age. ■ No data are available regarding the presence of voriconazole in human milk, the effects of voriconazole on the breast-fed infant, or the effects on milk production. ■ Safety and effectiveness for use in pediatric patients under 2 years of age not established. ■ Frequency of phototoxicity reactions is higher in pediatric patients. Stringent measures for photoprotection are warranted; see Patient Education. In pediatric patients experiencing photoaging injuries such as lentigines or ephelides, sun avoidance and dermatologic follow-up are recommended, even after discontinuation of therapy. ■ A higher incidence of liver enzyme elevations was observed in pediatric patients.

Elderly:

Safety profile similar to younger adults. ■ Use caution; consider decreased cardiac, hepatic, or renal function and effects of concomitant disease or other drug therapy. ■ Monitor liver and renal function closely.

DRUG/LAB INTERACTIONS

Interactions are numerous and potentially life threatening. Review of drug profile by pharmacist is imperative.

Contraindicated with **CYP3A4 substrates** (e.g., **pimozide, quinidine**); increased plasma concentrations of these drugs may result in QT prolongation and torsades de pointes. ■ **Contraindicated** with **long-acting barbiturates, carbamazepine, rifampin, St. John's wort, and tolvaptan;** these drugs may significantly increase metabolism and decrease serum concentrations of voriconazole. ■ **Contraindicated** with **high-dose (400 mg every 12 hours) ritonavir**; decreases serum concentrations of voriconazole. **Low-dose ritonavir (100 mg every 12 hours)** reduces voriconazole concentration to a lesser extent. Coadministration should be avoided unless assessment of the benefit versus risk to the patient justifies voriconazole use. ■ **Contraindicated** with **sirolimus**; metabolism of sirolimus is decreased, and serum concentrations are significantly increased by voriconazole. ■ **Contraindicated** with **rifabutin**; voriconazole significantly increases the serum concentrations of rifabutin, and rifabutin significantly decreases voriconazole serum concentrations. ■ Coadministration of standard doses of voriconazole with **efavirenz** doses of 400 mg every 24 hours or higher is **contraindicated**. Voriconazole increases serum concentrations of efavirenz, and efavirenz decreases serum concentrations of voriconazole. If coadministration is required, dose adjustment of both drugs is indicated. Increase voriconazole oral maintenance dose to 400 mg every 12 hours and decrease efavirenz to 300 mg every 24 hours. Restore the initial dose of efavirenz when treatment with voriconazole is discontinued. ■ **Contraindicated** with **ergot alkaloids**; serum concentrations of ergot alkaloids may be increased and may lead to ergotism. ■ Avoid concomitant use with **fluconazole**. Potential for voriconazole toxicity remains if voriconazole is initiated within 24 hours of the last dose of fluconazole. ■ May decrease the metabolism and increase serum levels of

cyclosporine. If concurrent administration with voriconazole is indicated, reduce the dose of cyclosporine by one-half and monitor cyclosporine serum levels frequently. When voriconazole is discontinued, monitor cyclosporine levels frequently and increase the dose as necessary. ■ May decrease the metabolism and increase serum levels of **methadone** and increase risk of QT prolongation. If concurrent administration with voriconazole is indicated, monitor closely and decrease dose of methadone as necessary. ■ Increases concentration and half-life of **alfentanil, fentanyl, oxycodone, and sufentanil**. Dose reduction and extended monitoring recommended. ■ May decrease the metabolism and increase serum levels of **tacrolimus and tolvaptan**. If concurrent administration with voriconazole is indicated, reduce the dose of tacrolimus by one-third and monitor tacrolimus serum levels frequently. When voriconazole is discontinued, monitor tacrolimus levels frequently and increase the dose as necessary. ■ Concurrent use with **warfarin** may cause a significant increase in PT or INR. Monitor PT or INR closely and adjust warfarin dose as necessary. ■ May decrease the metabolism and increase serum concentrations of CYP3A4 substrates, such as selected **HMG-CoA reductase inhibitors, selected benzodiazepines** (e.g., alprazolam, midazolam, triazolam), **selected calcium channel blockers** (e.g., felodipine), **vinca alkaloids** (e.g., vinblastine, vincristine), and CYP2C9 substrates such as **sulfonylureas** (e.g., glipizide, glyburide, tolbutamide) and **NSAIDs**. In patients receiving a **vinca alkaloid**, reserve the use of azole antifungals, including voriconazole, for patients who have no alternative antifungal treatment options. To reduce the potential for toxic effects that may be caused by these drugs (e.g., rhabdomyolysis, prolonged sedative effect, cardiac toxicity, GI toxicity, neurotoxicity, hypoglycemia), close monitoring for toxic effects of all of these drugs is indicated, and in most cases dose reduction is indicated during concomitant administration of voriconazole. ■ Concomitant administration with **everolimus**, a CYP3A4 inhibitor and substrate and a P-pg substrate, is not recommended; plasma exposure of everolimus is likely to be increased. ■ Concurrent use with **phenytoin** may require dose adjustments of both drugs. Phenytoin increases metabolism and decreases serum concentrations of voriconazole. An increased dose of voriconazole is indicated; see Dose Adjustments. Voriconazole decreases the metabolism of phenytoin and increases serum concentrations. Monitor phenytoin serum concentrations and reduce dose as necessary to avoid toxicity. ■ May decrease the metabolism and increase serum levels of **selected HIV protease inhibitors** (e.g., amprenavir, nelfinavir, saquinavir). Selected HIV protease inhibitors (e.g., amprenavir, saquinavir) may decrease the metabolism of voriconazole and increase its serum levels. Monitor frequently for drug toxicity with coadministration of voriconazole and HIV protease inhibitors. ■ May decrease the metabolism and increase serum levels of **omeprazole**. If concurrent administration with voriconazole is indicated, reduce a dose of omeprazole of 40 mg or more by one-half. The metabolism of other selected proton pump inhibitors may react similarly. ■ **Nonnucleoside reverse transcriptase inhibitors** (NNRTIs) such as delavirdine may decrease the metabolism of voriconazole and increase its serum concentrations. Voriconazole may inhibit the metabolism of the same NNRTIs and increase their serum levels. Monitor frequently for drug toxicity with coadministration of voriconazole and NNRTIs. ■ Concurrent use with **other nephrotoxic drugs** (e.g., aminoglycosides, cyclosporine) may result in decreased renal function or acute renal failure. ■ Concurrent use with **oral contraceptives** may increase concentrations of both drugs. Monitor for adverse events related to each drug. Should not reduce the effectiveness of oral contraception.

SIDE EFFECTS

Adult:

Abdominal pain, chills, diarrhea, dyspnea, fever, hallucinations, headache, hypokalemia, increases in liver function tests, nausea, peripheral edema, rash, respiratory disorders, sepsis, tachycardia, visual disturbances, and vomiting occur most frequently.

Pediatric patients:

Abdominal distention, abdominal pain, abnormal ALT, abnormal LFT, constipation, cough, diarrhea, dizziness, dyspnea, epistaxis, fever, hallucinations, headache, hemoptysis, hyperglycemia, hypertension, hypoalbuminemia, hypocalcemia, hypokalemia, hypomagnesemia, hypophosphatemia, hypotension, mucosal inflammation, nausea, peripheral edema, photophobia, rash, renal impairment, tachycardia, thrombocytopenia, upper respiratory tract infections, visual disturbances, and vomiting are most common. Side effects that most often led to discontinuation of therapy include elevated liver function tests, rash, and visual disturbances. Blurred vision, color vision change, and/or photophobia are common but may be associated with higher serum concentrations and/or doses. Hypersensitivity reactions, including anaphylaxis, have been reported. Rarely, Stevens-Johnson syndrome and photosensitivity skin reactions have been reported. In patients with photosensitivity reactions, squamous cell cancer and melanoma have been reported. Numerous other side effects may occur, including QT prolongation and, rarely, torsades de pointes.

Post-Marketing:

Pancreatitis in pediatric patients, prolonged visual adverse events, including optic neuritis and papilledema.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. If a hypersensitivity reaction (e.g., an infusion reaction) occurs, discontinue the infusion and treat with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., dexamethasone), or bronchodilators (e.g., albuterol) as indicated. Consider discontinuation of voriconazole if liver function tests are elevated and/or clinical S/S of liver disease attributable to voriconazole develop, if visual disturbances occur, if an increase in serum creatinine occurs, if a rash develops (may be the first sign of an exfoliative skin disorder), or if a phototoxic reaction occurs. No known specific antidote. Hemodialysis may assist in the removal of some voriconazole in accidental overdose and in the removal of SBECD. Resuscitate as indicated.

Generic drugs: Z

ZIDOVUDINE
ZIV-AFLIBERCEPT
ZOLEDRONIC ACID

Z

ZIDOVUDINE BBW

(zye-**DOH**-vyou-deen)
Azidothymidine, AZT, Retrovir
Antiviral
pH 5.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Treatment of HIV infection (symptomatic or asymptomatic):

1 mg/kg every 4 hours. Initiate oral therapy as soon as possible. (The recommended oral dose of zidovudine is 300 mg twice daily in combination with other antiretroviral agents.) Usually part of a multidrug regimen; see Drug/Lab Interactions.

Prevention of maternal-fetal HIV transmission:

2 mg/kg of total body weight over 1 hour when labor begins. Follow with an infusion of 1 mg/kg/hr (of total body weight) until umbilical cord is clamped.

PEDIATRIC DOSE

See Maternal/Child.

To avoid medication errors when preparing pediatric doses, use extra care to calculate the appropriate dose based on body weight (kg). Follow with oral therapy; see comments in Usual Dose.

Treatment of HIV infections in pediatric patients 4 weeks to less than 18 years of age, weight greater than 4 kg:

Recommendations for pediatric oral dosing (capsules or syrup) can be found in the prescribing information. Should not exceed the recommended adult dose. See Dose Adjustments.

NEONATAL DOSE

See Maternal/Child.

Treatment of HIV infections (unlabeled):

Oral dosing preferred but may be given IV.

Premature neonates (gestational age under 30 weeks) under 6 weeks of age:

1.5 mg/kg IV every 12 hours. Increase to 2.3 mg/kg every 12 hours at 4 weeks of age.

Premature neonates (gestational age 30 to 35 weeks) under 6 weeks of age:

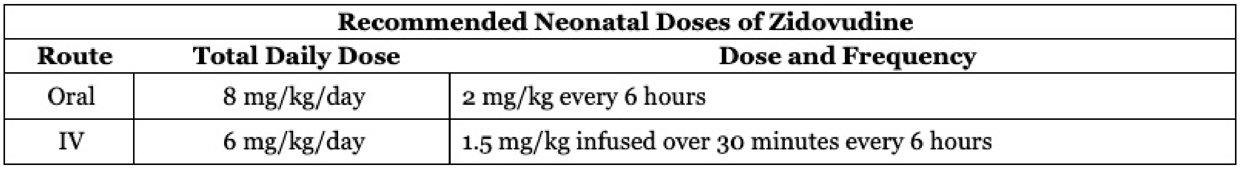
1.5 mg/kg IV every 12 hours. Increase to 2.3 mg/kg IV every 12 hours at 15 days of age.

Full-term infants (gestational age 35 weeks or more) under 6 weeks of age:

3 mg/kg IV every 12 hours.

Prevention of maternal-fetal HIV transmission:

Start neonatal dosing within 12 hours after birth and continue through 6 weeks of age. Oral dosing preferred but may be given IV. Consider impaired hepatic or renal function; see Precautions.



Recommended Neonatal Doses of Zidovudine

Route	Total Daily Dose	Dose and Frequency
Oral	8 mg/kg/day	2 mg/kg every 6 hours
IV	6 mg/kg/day	1.5 mg/kg infused over 30 minutes every 6 hours

Use an appropriate-sized syringe with 0.1-mL graduation to ensure accurate dosing of the syrup formulation in neonates.

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy. ■ Reduce dose to 1 mg/kg every 6 to 8 hours in patients with a CrCl less than 15 mL/min or in patients with ESRD who are being maintained on hemodialysis or peritoneal dialysis. ■ Data are insufficient to recommend dose adjustment in patients with hepatic impairment. Monitor for hematologic toxicity. ■ Dose interruption may be required in the presence of significant anemia and/or neutropenia. ■ Dose adjustment may be required in anemia and/or with other drugs. See Monitor, Drug/Lab Interactions, and Antidote.

DILUTION

Each vial of zidovudine contains 200 mg in 20 mL (10 mg/mL). Withdraw the calculated dose and add to a sufficient volume of D5W to achieve a final concentration no greater than 4 mg/mL. To avoid medication errors when preparing a pediatric dose, use extra care to calculate the appropriate dose based on body weight (kg).

Filters:

Not required by manufacturer; no further data available from manufacturer.

Storage:

Store undiluted vials at 15° to 25° C (59° to 77° F). Protect from light. Chemically and physically stable after dilution for 24 hours at RT or 48 hours refrigerated at 2° to 8° C (36° to 46° F). However, as an added precaution against microbial contamination, manufacturer recommends use within 8 hours if stored at 25° C (77° F) and 24 hours if refrigerated.

COMPATIBILITY

Manufacturer states, "Admixture in biologic or colloidal fluids (e.g., blood products, protein solutions) is not recommended."

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Intermittent infusion:

Each single dose properly diluted must be delivered at a constant rate over 1 hour. Avoid rapid infusion or IV bolus.

Continuous infusion: Prevention of maternal-fetal HIV transmission:

2 mg/kg equally distributed over 1 hour, followed by 1 mg/kg/hr until umbilical cord clamped.

Neonates:

A single dose infused over 30 minutes.

ACTIONS

A pyrimidine nucleoside analog active against HIV. Through a specific process this thymidine analog interferes with reverse transcriptase, thus inhibiting viral replication. Metabolized by glucuronidation in the liver and excreted through the kidneys. Oral dosing half-life is approximately 0.5 to 3 hours in adults. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of HIV-1 infection in combination with other antiretroviral agents. ■ Prevention of maternal-fetal HIV-1 transmission. In most cases, should be given in combination with other antiretroviral drugs. Protocol includes oral zidovudine beginning between week 14 and week 34 of gestation, continuing until labor begins, IV dosing during labor, and zidovudine syrup or IV dosing to the newborn; see Maternal/Child.

CONTRAINDICATIONS

Life-threatening hypersensitivity reactions to any of the components.

PRECAUTIONS

For IV use only. Do not give IM or SC. ■ Incidence of adverse reactions appears to increase with disease progression. ■ Has been associated with hematologic toxicity, including neutropenia and severe anemia, particularly in patients with advanced HIV. ■ Use with caution in patients with bone marrow compromise as indicated by a granulocyte count of less than 1,000/mm^3 or hemoglobin below 9.5 Gm/dL. Hematologic toxicities appear to be related to pretreatment bone marrow reserve and to dose and duration of therapy. ■ Prolonged use of zidovudine has been associated with symptomatic myopathy and myositis with pathologic changes similar to those produced by HIV disease. ■ Lactic acidosis and severe hepatomegaly with steatosis have been reported with the use of some nucleoside analogs, including zidovudine. Deaths have occurred. Female sex and obesity may increase risk. Suspend therapy in any patient who develops clinical or laboratory findings suggestive of lactic acidosis or pronounced hepatotoxicity (which may include hepatomegaly and steatosis, even in the absence of marked transaminase elevations). ■ Use with caution in patients with severe hepatic impairment; may be at increased risk for hematologic toxicity. ■ Hepatic decompensation has occurred in HIV/HCV co-infected patients receiving combination antiretroviral therapy for HIV and interferon alfa with or without ribavirin for HCV. ■ Use with caution in patients with severely impaired renal function (CrCl less than 15 mL/min); see Dose Adjustments. ■ Immune reconstitution syndrome has been reported in patients treated with combination antiretroviral therapy, including zidovudine. Patients may develop an inflammatory response to indolent opportunistic infections (e.g., *Mycobacterium avium*, CMV, *Pneumocystis jiroveci* pneumonia [PCP], or tuberculosis). May require further evaluation and treatment. ■ Autoimmune disorders (e.g., Graves' disease, polymyositis, and Guillain-Barré syndrome) have been reported in the setting of immune reconstitution; may occur months after initiation of therapy. ■ Treatment has been associated with loss of subcutaneous fat. The incidence and severity of lipoatrophy are related to cumulative exposure. The fat loss (which is most evident in the face, limbs, and buttocks) may be only partially reversible, and improvement may take months to years after switching to a non–zidovudine-containing regimen. ■ Vial stoppers contain dry natural rubber latex (a latex derivative); may cause hypersensitivity reactions in latex-sensitive individuals. ■ See Drug/Lab Interactions.

Monitor:

Obtain blood cell counts to monitor for hematologic toxicity, including neutropenia, severe anemia, and occasionally reversible pancytopenia. Anemia may occur as early as 2 to 4 weeks. Neutropenia usually occurs after 6 to 8 weeks of therapy; dosage adjustments and/or transfusions may be required. More frequent monitoring is required in patients with poor bone marrow reserve and advanced disease. ■ Monitor liver function. ■ Obtain baseline CD4 lymphocyte count and monitor as indicated. ■ Regularly assess for signs of lipoatrophy during therapy. If feasible, therapy should be switched to an alternative regimen if there is suspicion of lipoatrophy. ■ Closely monitor patients receiving zidovudine and interferon alfa, with or without ribavirin (Rebetol), for treatment-associated toxicities, especially hepatic decompensation, neutropenia, and anemia. Discontinuation of zidovudine and dose reduction or discontinuation of interferon, ribavirin, or both may be required if worsening clinical toxicities are seen (e.g., hepatic decompensation [e.g., Child-Pugh score greater than 6]). ■ Observe closely; not a cure for HIV infections. Patients may acquire illnesses associated with AIDS or AIDS-related complex (ARC), including opportunistic infections. ■ See Drug/Lab Interactions.

Patient Education:

Zidovudine is not a cure. Remain under the care of a physician when using zidovudine, and avoid actions that can spread HIV-1 infection to others. ■ Promptly report abdominal pain, decreased appetite, diarrhea, jaundice, muscle weakness, shortness of breath, rapid breathing, or unusual sleepiness; may indicate lactic acidosis or hepatotoxicity. ■ Major side effects are neutropenia and/or anemia. ■ Requires frequent lab work and close follow-up with physician; keep all appointments. ■ Inform health care provider of an allergy to latex. ■ Promptly report S/S of infection, because inflammation from a previous infection may occur soon after combination antiretroviral therapy, including when zidovudine is started. ■ Loss of subcutaneous fat may occur; regular assessments indicated. ■ Manufacturer has a pregnancy exposure registry that monitors pregnancy outcomes in women exposed to zidovudine during pregnancy. ■ Check with physician before taking any other medications.

Maternal/Child:

Safety for use during pregnancy has been evaluated. Risk versus benefit appears justified only in HIV-infected mothers. Congenital deformities not increased in studies. Hyperlactatemia, which may be due to mitochondrial dysfunction, has been reported in infants with in utero exposure to zidovudine-containing products. Because the fetus is most susceptible to the potential teratogenic effects of drugs during the first 10 weeks of gestation and because the risks of therapy with zidovudine during this period are not fully known, women in the first trimester of pregnancy who do not require immediate initiation of antiretroviral therapy for their own health may consider delaying use. (Indication for prevention of maternal-fetal HIV-1 transmission is based on use after 14 weeks of gestation.) ■ Discontinue breast-feeding because of the potential for HIV-1 transmission (in HIV-negative infants), development of viral resistance (in HIV-positive infants), and serious adverse reactions in breast-fed infants. ■ Has been studied in HIV-infected pediatric patients over 6 weeks of age who have HIV-related symptoms or are asymptomatic with abnormal lab values, indicating significant HIV-related immunosuppression. Has also been studied in neonates perinatally exposed to HIV. ■ To monitor maternal-fetal outcomes, an Antiretroviral Pregnancy Registry has been established. See prescribing information.

Elderly:

Differences in response between elderly patients and younger patients have not been identified. Dose selection should be cautious; see Dose Adjustments. Consider impaired hepatic and renal function.

DRUG/LAB INTERACTIONS

Probenecid may inhibit glucuronidation or reduce renal excretion of zidovudine, increasing zidovudine toxicity. ■ Use with **atovaquone, fluconazole, methadone,**

or **valproic acid** may increase zidovudine serum concentrations; monitoring indicated; dose adjustment of zidovudine is not indicated. ■ **Rifamycins** (e.g., rifampin) may increase clearance, reduce zidovudine serum levels, and reduce effectiveness. ■ Antagonized by **doxorubicin, stavudine, and ribavirin**. Avoid concurrent use. ■ Exacerbation of anemia due to ribavirin has been seen in patients co-infected with HIV/HCV when zidovudine is part of the HIV regimen; coadministration is not advised. ■ Hematologic toxicity increased with **ganciclovir, interferons, or other bone marrow suppressants or cytotoxic agents**. Close clinical and laboratory monitoring indicated if coadministration is necessary. ■ **Phenytoin** levels may increase or decrease; monitor carefully to ensure proper dosing. ■ **Phenytoin** may also increase zidovudine levels by decreasing clearance. ■ Use with **acyclovir** may cause neurotoxicity (drowsiness, lethargy). ■ Combination therapy with zidovudine and **interferon alfa,** with or without **ribavirin**, may increase risk of hepatic decompensation, neutropenia, and anemia. Discontinuation of zidovudine and/or dose reduction or discontinuation of interferon alfa, ribavirin, or both should be considered if worsening clinical toxicities are observed. ■ Prescribing information states that dose modification is also not warranted with coadministration of **clarithromycin, lamivudine, probenecid, or rifampin**. Other sources suggest drug adjustments with some adverse reactions.

SIDE EFFECTS

Frequency and severity of adverse events are greater in patients with more advanced infection at the time of initiation of treatment. Anorexia, headache, malaise, nausea, and vomiting are most common with oral and IV administration. Anemia and neutropenia were reported frequently with IV administration. Abdominal cramps, abdominal pain, anaphylaxis, arthralgia, asthenia, chills, constipation, dyspepsia, fatigue, granulocytopenia, hepatomegaly (severe), hyperbilirubinemia, increased liver function tests (e.g., ALT, AST, alkaline phosphatase), injection site reaction (e.g., pain, redness), insomnia, musculoskeletal pain, myalgia, neuropathy, pancytopenia (reversible), and thrombocytopenia have also been reported. Side effects most commonly reported in ***pediatric patients*** were anemia, cough, fever, and neutropenia.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Moderate anemia or granulocytopenia may respond to a reduction in dose. Interrupt zidovudine therapy for significant anemia (hemoglobin less than 7.5 Gm/dL or a greater than 25% reduction from baseline) or significant neutropenia (granulocyte count less than 750/mm^3 or a greater than 50% reduction from baseline). Transfusions may be required. If marrow recovery occurs following dose interruption, resumption of therapy may be appropriate using adjunctive measures such as epoetin alfa (Epogen). Suspend treatment if clinical or laboratory findings suggestive of lactic acidosis or pronounced hepatotoxicity occur. Rash may be the first sign of a more serious reaction (e.g., anaphylaxis, Stevens-Johnson syndrome); notify physician and treat with diphenhydramine, epinephrine, and corticosteroids as indicated. Antimicrobial therapy may be indicated to treat opportunistic infections. Not removed by hemodialysis or peritoneal dialysis.

ZIV-AFLIBERCEPT

(**ZIV**-a-**FLIB**-er-sept)
Zaltrap
Angiogenesis inhibitor
Vascular endothelial growth factor (VEGF) inhibitor
Antineoplastic
pH 6.2

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Ziv-aflibercept:

4 mg/kg as an infusion over 1 hour every 2 weeks. Administer before any component of the FOLFIRI regimen (5-fluorouracil [5-FU], leucovorin, and irinotecan) on the day of treatment. Continue until disease progression or unacceptable toxicity. See monographs for 5-fluorouracil, leucovorin, and irinotecan to incorporate all requirements into this regimen.

DOSE ADJUSTMENTS

Ziv-Aflibercept Dose Adjustments[a]

Indication	Recommended Dose or Action
Neutrophil count less than 1,500/mm^3 (1.5 × 10^9/L)	Withhold or delay dosing until neutrophil count is at or above 1.5 × 10^9/L (1,500/mm^3).
Elective surgery	Withhold for at least 4 weeks before elective surgery.
Recurrent or severe hypertension	Withhold until hypertension is controlled, then resume at a permanently reduced dose of 2 mg/kg.
Proteinuria at or above 2 Gm/24 hr	Withhold ziv-aflibercept. Resume when proteinuria decreases to less than 2 Gm/24 hr.
Recurrent proteinuria	Withhold ziv-aflibercept until proteinuria is less than 2 Gm/24 hr, then resume at a permanently reduced dose of 2 mg/kg.
Severe hemorrhage, GI perforation, compromised wound healing, fistula formation, hypertensive crisis or hypertensive encephalopathy, arterial thromboembolic events, nephrotic syndrome or thrombotic microangiopathy, and/or reversible posterior leukoencephalopathy syndrome (RPLS)	Discontinue ziv-aflibercept.
Age, gender, or race; mild, moderate, or severe renal impairment or mild or moderate hepatic impairment; see Precautions	No dose adjustment required.

[a] For toxicities related to irinotecan, 5-FU, or leucovorin, refer to individual monographs.

DILUTION

Available in single-dose vials containing 100 mg/4 mL or 200 mg/8 mL (25 mg/mL). A clear, colorless to pale yellow solution. Do not use if the solution is discolored or cloudy or contains particles. Do not re-enter the vial after the initial puncture. Withdraw the prescribed dose from the vial and dilute in NS or D5W to achieve a final concentration of 0.6 to 8 mg/mL. For example, in a 70-kg patient:

Weight in kg × Dose in mg/kg = Calculated dose of drug

(70 kg × 4 mg/kg = 280 mg)

Calculated dose in mg ÷ Drug concentration (25 mg/mL) = Volume of drug required

(280 mg ÷ 25 mg/mL = 11.2 mL of drug)

Dilution in a 50-mL infusion bag plus the 11.2 mL of drug would yield 4.6 mg/mL. Dilution in a 250-mL infusion bag plus the 11.2 mL of drug would yield 1.1 mg/mL. Use PVC infusion bags containing DEHP or polyolefin infusion bags.

Filters:

Administer through a 0.2-micron polyethersulfone filter. Do not use filters made of polyvinylidene fluoride (PVDF) or nylon.

Storage:

Store vials in refrigerator at 2° to 8° C (36° to 46° F). Keep in original carton to protect from light. Diluted solution may be stored refrigerated for up to 24 hours or stored at RT (20° to 25° C [68° to 77° F]) for up to 8 hours. Discard any unused portion left in vial or infusion bag.

COMPATIBILITY

Manufacturer states, “Do not combine ziv-aflibercept with other drugs in the same infusion bag or intravenous line.”

RATE OF ADMINISTRATION

Administer using an infusion set made of PVC containing DEHP, DEHP-free PVC containing trioctyl-trimellitate (TOTM), polypropylene, polyethylene-lined PVC, or polyurethane through a 0.2-micron polyethersulfone filter. Do not use filters made of polyvinylidene fluoride (PVDF) or nylon.

A single dose as an infusion over 1 hour.

ACTIONS

A recombinant fusion protein consisting of vascular endothelial growth factor (VEGF)–binding portions from the extracellular domains of human VEGF receptors 1 and 2 fused to the Fc portion of the human IgG1. It is a soluble receptor that binds to specific components of human VEGF. Inhibits the binding and activation of the specific receptors, resulting in decreased neovascularization and decreased vascular permeability. In animals ziv-aflibercept was shown to inhibit the proliferation of endothelial cells, thereby inhibiting the growth of new blood vessels. Elimination half-life is approximately 6 days (range 4 to 7 days). Steady-state concentrations reached by the second dose.

INDICATIONS AND USES

Treatment of metastatic colorectal cancer (mCRC) that is resistant to or has progressed following an oxaliplatin-containing regimen. Used in combination with 5-fluorouracil, leucovorin, and irinotecan (FOLFIRI).

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Do not administer as an IV push or bolus. ■ Severe and sometimes fatal hemorrhagic events, including GI hemorrhage, has been reported in patients who have received ziv-aflibercept; occurred in 38% of patients treated in combination with FOLFIRI. Do not administer to patients with severe hemorrhage. ■ GI perforation, including fatal GI perforation, can occur. ■ Impaired wound healing was reported in 2 patients receiving ziv-aflibercept/FOLFIRI. Withhold ziv-aflibercept for at least 4 weeks before elective surgery and do not resume for at least 4 weeks after major surgery and until the surgical wound is adequately healed. For minor surgery (e.g., CV access port placement, biopsy, tooth extraction), ziv-aflibercept may be resumed once the surgical wound is fully healed. ■ Incidence of fistula formation is increased. Anal, enterovesical, enterocutaneous, colovaginal, and intestinal site fistulas have been reported. ■ Risk of Grade 3 or 4 hypertension is increased. Grade 3 is defined as requiring an adjustment in existing antihypertensive therapy or treatment with more than one drug. Grade 4 is defined as a hypertensive crisis. ■ Risk of arterial thromboembolic events is increased. ■ Severe proteinuria, nephrotic syndrome, and thrombotic microangiopathy (TMA) have been reported. ■ Risk of neutropenic complications (e.g., febrile neutropenia and neutropenic infection) is increased. ■ Incidence of severe diarrhea and dehydration is increased. ■ Reversible posterior leukoencephalopathy syndrome (RPLS) has been reported. ■ A protein product; has potential for immunogenicity. ■ No data available for patients with severe hepatic impairment. ■ See Monitor and Antidote.

Monitor:

Obtain baseline CBC with differential and repeat every 2 weeks before each dose of ziv-aflibercept. Withhold or delay dosing until neutrophil count is at or above 1.5×10^9/L (1,500/mm^3). ■ Obtain baseline BP history and monitor BP a minimum of every 2 weeks or more frequently as clinically indicated. ■ Management with antihypertensive medications is indicated. Closely monitor patients already taking hypertensive medications. ■ Monitor for S/S of bleeding (e.g., GI hemorrhage, hematuria, hemoptysis, intracranial hemorrhage, postprocedural hemorrhage, pulmonary hemorrhage). ■ Monitor for S/S of GI perforation. ■ Monitor for S/S of fistula formation. ■ Monitor for S/S of arterial thromboembolic events (e.g., transient ischemic attack [TIA], cerebrovascular accident [CVA], and angina pectoris). ■ Monitor proteinuria by urine dipstick analysis and/or urinary protein creatinine ratio (UPCR) for development or worsening of proteinuria. Obtain a 24-hour urine collection in patients with a UPCR greater than 1 or a dipstick for protein of 2+ or more. ■ Diarrhea may be severe; monitor bowel history and encourage adequate hydration to prevent dehydration. ■ Monitor for neurologic S/S that may be consistent with RPLS (e.g., confusion, headache, seizures, visual changes). Diagnosis confirmed by MRI. ■ See Dose Adjustments, Precautions, and Antidote.

Patient Education:

May cause hypertension; monitor BP. ■ Promptly report abdominal pain, bleeding, elevated BP, fever or other signs of infection, light-headedness, neurologic symptoms, severe diarrhea, severe headache, or vomiting. ■ Wound healing is impaired; do not undergo surgery or procedures (including tooth extractions) without the knowledge of a health care provider. ■ Risk of chest pain, TIAs, and CVAs increased. ■ Risk of fetal harm; highly effective contraception required in males and females during and for at least 3 months following the last dose of therapy. If a pregnancy occurs in patient or partner, notify health care provider immediately. ■ May impair reproductive function and fertility in both males and females.

Maternal/Child:

Based on its mechanism of action, ziv-aflibercept can cause fetal harm. Was embryotoxic and teratogenic in rabbits at doses lower than required for humans. Highly effective contraception required in both males and females; see Patient Education. ■ Discontinue breast-feeding during treatment and for 1 month after the last dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Incidence of asthenia, dehydration, diarrhea, dizziness, and weight loss increased. Monitor closely for dehydration and diarrhea.

DRUG/LAB INTERACTIONS

No drug-drug interaction studies have been conducted. ■ No clinically important pharmacokinetic drug-drug interactions have been found between ziv-aflibercept and **irinotecan/SN-38 or 5-FU.**

SIDE EFFECTS

Abdominal pain, decreased appetite, diarrhea, dysphonia, epistaxis, fatigue, headache, hypertension, increased AST and ALT, increased SCr, leukopenia, neutropenia, proteinuria, stomatitis, thrombocytopenia, and weight loss are most common. The most serious side effects include arterial thrombotic events, compromised wound healing, diarrhea and dehydration, fistula formation, GI perforation, hemorrhage, hypertension, neutropenia and neutropenic complications, proteinuria, and RPLS. Asthenia, dyspnea, hemorrhoids, infection, oropharyngeal pain, palmar-plantar erythrodysesthesia syndrome, proctalgia, rectal hemorrhage, rhinorrhea, skin hyperpigmentation, upper abdominal pain, urinary tract infections, and venous thromboembolic events have been reported.

Post-Marketing:

Cardiac failure, decreased ejection fraction, osteonecrosis of the jaw.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Discontinue for severe hemorrhage, GI perforation, impaired wound healing, fistula formation, hypertensive crisis or hypertensive encephalopathy, arterial thromboembolic events, nephrotic syndrome or thrombotic microangiopathy, and/or reversible posterior leukoencephalopathy syndrome (RPLS). See Dose Adjustments for instructions on dose reduction, holding treatment, and resuming treatment. Treat anaphylaxis with oxygen, antihistamines (diphenhydramine), epinephrine, and corticosteroids. Maintain a patent airway. Resuscitate if indicated.

ZOLEDRONIC ACID

(**ZOH**-leh-dron-ick **AS**-id)

Reclast ■ Zometa
Bisphosphonate
pH 6 to 7 ■ pH 2

USUAL DOSE

Reclast and Zometa

Pretreatment:

Verify pregnancy status. Baseline studies and an oral examination indicated before initiation of therapy; see Monitor and Precautions. Prehydration required. Always used with adequate hydration and appropriate monitoring. See Dose Adjustments, Precautions, and Monitor.

Reclast

Administration of acetaminophen after Reclast administration may reduce the incidence of acute-phase reaction symptoms; see Side Effects. In clinical studies, a standard dose of acetaminophen was given with the infusion and for the next 72 hours as needed.

Treatment of Paget's disease:

One dose of 5 mg as an infusion over no less than 15 minutes. Supplemental calcium and vitamin D are required, particularly during the 2 weeks following administration.

Treatment of osteoporosis in men and postmenopausal women and treatment and prevention of glucocorticoid-induced osteoporosis:

A single dose of 5 mg given once a year as an infusion over at least 15 minutes.

Prevention of osteoporosis in postmenopausal women:

A single dose of 5 mg given every 2 years as an infusion over at least 15 minutes.

Zometa

Hypercalcemia of malignancy (corrected serum calcium equal to or greater than 12 mg/dL [3 mmol/L]):

One dose of 4 mg as an infusion over no less than 15 minutes.

Experience is limited, but retreatment with the same dose may be considered if serum calcium does not return to normal or remain normal after initial treatment. Wait at least 7 days from completion of the first infusion to allow full response.

Multiple myeloma and metastatic bone lesions from solid tumors:

4 mg as an infusion over no less than 15 minutes every 3 to 4 weeks. A CrCl greater than 60 mL is required; see Dose Adjustments. Optimal duration of therapy is unknown. Concurrent daily administration of PO calcium 500 mg and a multivitamin with 400 units vitamin D is recommended.

DOSE ADJUSTMENTS

Reclast and Zometa

Dose adjustment is not indicated based on age or race. Studies have not been conducted in patients with hepatic or severe renal impairment; see Dilution, Precautions, and Elderly.

Reclast

No dose adjustment required in patients with a CrCl of 35 mL/min or greater.

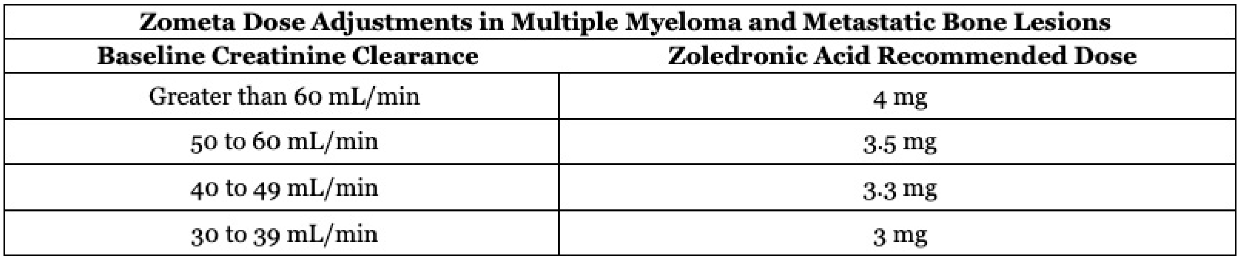
Zometa

Hypercalcemia of malignancy:

Dose adjustments are not necessary in patients with mild to moderate renal impairment before beginning treatment (SCr less than 4.5 mg/dL). If renal function deteriorates, consider if the potential benefit of continued treatment outweighs the possible risk.

Multiple myeloma and metastatic bone lesions from solid tumors:

Reduce the initial and following doses in patients with mild to moderate renal impairment based on the following chart:



Zometa Dose Adjustments in Multiple Myeloma and Metastatic Bone Lesions

Baseline Creatinine Clearance	Zoledronic Acid Recommended Dose
Greater than 60 mL/min	4 mg
50 to 60 mL/min	3.5 mg
40 to 49 mL/min	3.3 mg
30 to 39 mL/min	3 mg

Measure SCr before each Zometa dose and withhold if renal condition deteriorates. In clinical studies, renal deterioration was defined as an increase in SCr of 0.5 mg/dL in patients with a normal baseline SCr and an increase in SCr of 1 mg/dL in patients with an abnormal baseline SCr. When the CrCl has returned to within 10% of the baseline value, resume dosing at the same dose administered before treatment interruption.

DILUTION

Reclast

A 5-mg dose is available in a 100-mL ready-to-infuse solution. If previously refrigerated, allow solution to reach room temperature before administration.

Zometa

Available in two formulations: (1) a single-use prediluted solution containing 4 mg in 100-mL solution, and (2) a concentrate containing 4 mg in 5 mL.

Single-use, ready-to-use-bottle:

100 mL of solution equals a 4-mg dose of zoledronic acid and may be administered

without further dilution.

Single-Use, Ready-to-Use Bottle Zometa Dilution Recommendations for Reduced Doses in Patients With a CrCl Less Than or Equal to 60 mL/min		
Remove and discard the following Zometa ready-to-use solution (mL)	**Replace with the following volume of NS or D5W (mL)**	**Dose (mg)**
12 mL	12 mL	3.5 mg
18 mL	18 mL	3.3 mg
25 mL	25 mL	3 mg

Concentrate with 4 mg in 5 mL for single use:

Vials contain overfill; measure accurately. Withdraw desired volume from vial as outlined in the following chart. Must be further diluted immediately in 100 mL of NS or D5W and given as an infusion.

4-mg Concentrate in 5 mL for Single Use Zometa Dilution Recommendations for Reduced Doses in Patients With a CrCl Less Than or Equal to 60 mL/min	
Recommended Dose (mg)	**Volume of Zometa (mL)**
4 mg	5 mL
3.5 mg	4.4 mL
3.3 mg	4.1 mL
3 mg	3.8 mL

Filters:

Not required by manufacturer; however, use of a filter should not have an adverse effect.

Storage:

Reclast: Store at CRT. Stable for 24 hours refrigerated at 2° to 8° C (36° to 46° F) after opening. ***Zometa:*** Store vials and ready-to-use container in carton at CRT. Use immediately after dilution or manipulation of ready-to-use container is preferred. Diluted solution may be refrigerated but must be used and the infusion completed within 24 hours of mixing. If refrigerated, bring to RT before administration. Do not store undiluted solution in a syringe (to avoid inadvertent injection).

COMPATIBILITY

Reclast and Zometa

Must not be mixed with calcium or other divalent cation–containing infusion solutions (e.g., LR). Should be administered as a single IV solution in a line separate from all other drugs.

RATE OF ADMINISTRATION

A single dose equally distributed over no less than 15 minutes. After infusion is finished, flush IV line with 10 mL NS. An increase in renal toxicity that can progress to renal failure can result from shorter infusion times.

Reclast

A vented IV set is required.

ACTIONS

Zoledronic Acid

A bisphosphonate that inhibits osteoclast-mediated bone resorption. Used as a bone resorption inhibitor in Paget's disease (Reclast) and as a hypocalcemic agent to reduce hypercalcemia in oncology patients (Zometa). After administration, it rapidly partitions to the bone and localizes preferentially at sites of high bone turnover. Inhibits osteoclastic (destructive to bone) activity and induces osteoclast apoptosis (fragmentation of a cell into particles for elimination). Blocks the osteoclastic resorption of mineralized bone and cartilage through its binding to bone. Inhibits the increased osteoclastic activity and skeletal calcium release induced by various tumors. Decreases serum calcium and phosphorus and increases urinary calcium and phosphorus excretion. Plasma protein binding of zoledronic acid is low. Not metabolized. Most bound to bone and slowly released back into the systemic circulation. Primarily excreted intact via the kidney. Half-life is triphasic with a terminal half-life of 146 hours.

Reclast

In Paget's disease, it localizes preferentially at sites of high bone turnover and promotes bone of normal quality with no evidence of impaired bone remodeling or mineralization effect. Returns patients to normal levels of bone turnover; see Indications.

Zometa

In oncology patients with hypercalcemia, it reduces serum calcium concentrations by inhibiting bone resorption. Reduction in calcium levels is seen in 24 to 48 hours, but maximum response may take up to 7 days.

INDICATIONS AND USES

Reclast

Treatment of Paget's disease of the bone in men and women. Treatment indicated to induce remission (normalization of serum alkaline phosphatase) in patients with elevations in serum alkaline phosphatase of two times or higher than the upper limit of the age-specific reference range and in patients who are symptomatic or are at risk for complications from their disease. Paget's disease of the bone is a chronic focal skeletal disorder characterized by greatly increased and disorderly bone remodeling. Excessive osteoclastic bone resorption is followed by irregular osteoblastic new bone formation, which leads to replacement of the normal bone architecture by disorganized, enlarged, and weakened bone structure. ■ Prevention and treatment of osteoporosis in postmenopausal women. In osteoporosis diagnosed by a bone mineral density test or prevalent vertebral fractures, Reclast reduces the incidence of hip, vertebral, and nonvertebral osteoporosis-related fractures. In patients at high risk for fracture (defined as a recent low-trauma hip fracture), Reclast reduces the incidence of new clinical fractures. ■ Treatment to increase bone mass in men with osteoporosis. ■ Treatment and prevention of glucocorticoidinduced osteoporosis in men and women who are initiating or continuing systemic glucocorticoids in a daily dose that is equivalent to 7.5 mg or more of prednisone and who are expected to remain on glucocorticoids for at least 12 months.

Limitation of use:

Safety and effectiveness for treatment of osteoporosis are based on 3 years of clinical data. Optimal duration of therapy is unknown. Re-evaluate the need for continued therapy on a periodic basis. Consider discontinuation of therapy after 3 to 5 years in patients at low risk for fracture. Patients who discontinue therapy should have their risk for fracture re-evaluated periodically.

Zometa

Treatment of hypercalcemia of malignancy (HCM), which is defined as an albumin-corrected calcium (cCa) greater than or equal to 12 mg/dL (3 mmol/L) using the following formula:

$$\text{cCa in mg/dL} = \text{Ca in mg/dL} + 0.8\,[4\ \text{Gm/dL} - \text{Patient albumin (Gm/dL)}]$$

■ Treatment of patients with multiple myeloma and patients with documented bone metastases from solid tumors in conjunction with chemotherapy. Prostate cancer should have progressed after treatment with at least one hormonal therapy.

Limitation of use:

Safety and efficacy for use in the treatment of hypercalcemia associated with hyperparathyroidism or with other non–tumor-related conditions has not been established.

CONTRAINDICATIONS

Reclast and Zometa

Hypersensitivity to zoledronic acid or any of its components.

Reclast

Hypocalcemia in patients with a CrCl less than 35 mL/min, and in patients with evidence of acute renal impairment.

PRECAUTIONS (International units [IU])

Reclast and Zometa

A patient being treated with Zometa should not be treated with Reclast or another bisphosphonate (e.g., ibandronate, pamidronate). ■ Bisphosphonates have been associated with deterioration of renal function and potential renal failure. Multiple cycles of zoledronic acid, doses over 4 or 5 mg, and/or a rate of administration less than 15 minutes increase this risk. Patients who are elderly, are dehydrated, are receiving diuretics or other nephrotoxic drugs, or have pre-existing renal impairment may also be at increased risk. In trials and post-marketing events, renal deterioration progressing to renal failure and dialysis has occurred in patients, including those treated with approved doses infused over 15 minutes. ■ Use with caution in patients with aspirin-sensitive asthma; although not seen in zoledronic acid trials, bronchoconstriction has been reported when other bisphosphonates have been given to these patients. ■ Osteonecrosis of the jaw (ONJ) has been reported in patients receiving bisphosphonates. The majority of cases have been in cancer patients undergoing dental procedures. However, some cases have been reported in patients with postmenopausal osteoporosis treated with either oral or IV bisphosphonates. Risk factors include cancer, concomitant therapy (e.g., chemotherapy, radiotherapy, corticosteroids, angiogenesis inhibitors), and comorbid conditions (e.g., anemia, coagulopathies, infection, pre-existing oral disease). Risk may also increase with duration of exposure to bisphosphonates. Post-marketing experience suggests a greater frequency of reports based on tumor type (advanced breast cancer or multiple myeloma); see Drug/Lab Interactions. ■ A routine oral exam is recommended before beginning therapy with bisphosphonates. Patients, especially cancer patients, should consider appropriate preventive dentistry and avoid invasive dental procedures during bisphosphonate therapy. Dental surgery may exacerbate ONJ in patients who develop ONJ while undergoing bisphosphonate therapy. ■ Severe and occasionally incapacitating bone, joint, and/or muscle pain has been reported. Onset of symptoms may be days to months after initiation of therapy. Symptoms usually resolve when zoledronic acid is discontinued. A subset of patients had a recurrence of symptoms when rechallenged with the same drug or another bisphosphonate. ■ Atypical subtrochanteric and diaphyseal femoral fractures have been reported in bisphosphonate-treated patients. May be bilateral. Many patients report prodromal pain in the affected area (usually presenting as dull, aching thigh pain) weeks to months before a complete fracture occurs. Patients presenting with thigh or groin pain in the absence of trauma should be evaluated to rule out an incomplete femur fracture. Patients presenting with an atypical fracture should also be assessed for S/S of fracture in the contralateral limb. Poor healing of these fractures has also been reported. ■ Use with caution in patients with hepatic impairment; has not been adequately studied and data are limited. ■ See Monitor.

Reclast

Hypocalcemia may occur. Pre-existing hypocalcemia and disturbances of mineral metabolism must be treated before initiating therapy. Concurrent dosing with calcium and vitamin D during therapy is required and is especially important in the 2 weeks following Reclast administration. ■ Effectively treat disturbances of calcium and mineral metabolism (e.g., hypoparathyroidism, thyroid surgery, parathyroid surgery, malabsorption syndromes, excision of the small intestine) before initiating therapy with

Reclast.

Zometa

Calcium is bound to serum protein; concentration fluctuates with changes in blood volume. Changes in serum calcium (especially during rehydration) may not reflect true plasma levels. Measurement with ionized calcium levels is preferred. If unavailable, all calcium measurement should be corrected for albumin to establish a basis for treatment and evaluation of treatment. ■ Hypocalcemia has been reported. Cardiac arrhythmias and adverse neurologic events (numbness, seizures, tetany) have been reported secondary to severe hypocalcemia. Correct hypocalcemia before beginning Zometa therapy. Adequately supplement with calcium and vitamin D. ■ Mild or asymptomatic hypercalcemia will be treated with conservative measures (e.g., saline hydration, with or without diuretics [after correcting hypovolemia]). Consider patient's cardiovascular status. ■ Not recommended for patients with bone metastases with a SCr greater than 3 mg/dL (265 micromol/L) or for patients with hypercalcemia of malignancy with a SCr greater than 4.5 mg/dL (400 micromol/L). These patients were excluded from the studies. After considering other treatment options, use only if benefit outweighs risk of renal failure. ■ Retreatment may increase potential for renal failure; before retreatment, consider other available treatment options and risk versus benefit; evaluate serum creatinine before each dose. ■ May be used adjunctively with chemotherapy, radiation, or surgery.

Monitor:

Reclast and Zometa:

Serum phosphate levels may decrease (hypophosphatemia) and may require treatment. Short-term supplemental therapy may also be required for hypocalcemia or hypomagnesemia. ■ See Precautions and Drug/Lab Interactions.

Reclast:

S/S of Paget's disease range from no symptoms to severe morbidity due to bone pain, bone deformity, pathologic fractures, and neurologic and other complications. Serum alkaline phosphatase provides an objective measure of disease severity and response to therapy. Diagnosis can be confirmed by radiographic evidence. ■ Obtain baseline measurement of serum alkaline phosphatase, serum calcium, electrolytes, phosphate, magnesium, and SCr. Monitor as indicated. Obtain serum creatinine and calculate CrCl before each dose. ■ Supplemental calcium and vitamin D required; see Usual Dose. Very important in the 2 weeks following Reclast administration. ■ Adequate hydration required; a minimum of two glasses of liquid is recommended before dosing on day of administration. Additional hydration is required in patients undergoing diuretic therapy. ■ Monitor calcium and mineral levels (phosphate and magnesium) closely in patients with disturbances of calcium and mineral metabolism (e.g., hypoparathyroidism, thyroid surgery, parathyroid surgery, malabsorption syndromes, excision of the small intestine). ■ Bone mineral density should be evaluated 1 to 2 years after initiation of therapy in patients being treated for osteoporosis.

Zometa:

Obtain baseline measurements of serum calcium (corrected for serum albumin), electrolytes, phosphate, magnesium, SCr, and CBC with differential. Monitor all closely as indicated by baseline results. ■ Monitor SCr before each dose to identify renal deterioration. During clinical studies, deterioration was considered as an increase of 0.5 mg/dL if the patient had a normal baseline; if the patient had an abnormal baseline, deterioration was considered as an increase of 1 mg/dL. ■ Patients with cancer-related hypercalcemia are often dehydrated. Must be adequately hydrated orally and/or IV before treatment is initiated. Hydration with saline is preferred to facilitate the renal excretion of calcium and to correct dehydration. A pretreatment urine output of 2 L/day is recommended. Maintain adequate hydration and urine output throughout treatment. ■ Correct hypovolemia before using diuretics. ■ Avoid overhydration in patients with compromised cardiovascular status. Observe frequently for signs of fluid overload.

Patient Education:

Reclast and Zometa:

Review manufacturer’s medication guide. ■ Avoid pregnancy; use of effective birth control recommended during and after treatment. Report a suspected pregnancy; may cause fetal harm. ■ Regular visits and assessment of lab tests imperative. ■ Take only prescribed medications. Discuss all medications, allergies (including aspirin sensitivity), and medical history with physician. ■ Adequate hydration required. Drink at least two glasses of fluid before infusion. ■ Report abdominal cramps, chills, confusion, fever, muscle spasms, sore throat, and/or any new medical problems promptly. ■ Flu-like symptoms may occur within the first 3 days of therapy. Usually resolve within 3 days of onset but may last for up to 7 to 14 days. Administration of acetaminophen may reduce incidence of symptoms. ■ Good dental hygiene and routine dental care required. Obtain a dental exam before initiating therapy, and avoid invasive dental procedures during therapy. Report any oral symptoms such as loosening of a tooth, pain, swelling or nonhealing of sores, or discharge. ■ Report development of bone, joint, or muscle pain promptly. Onset of pain is variable. ■ Report thigh, hip, or groin pain promptly.

Reclast:

Calcium and vitamin D supplementation required to maintain calcium levels. ■ Tell your physician if you have had surgery to remove some or all of the parathyroid glands in your neck, have had sections of your intestine removed, or are unable to take calcium supplements. ■ Promptly report muscle spasms and/or numbness or tingling sensations (especially around the mouth); may indicate hypocalcemia. ■ Patients being treated with Reclast should not be treated with Zometa or other bisphosphonates.

Zometa:

Dietary restriction of calcium and vitamin D may be required in hypercalcemia of malignancy. ■ An oral calcium supplement of 500 mg and a multivitamin with 400 IU of vitamin D are recommended for patients with multiple myeloma and bone metastasis of solid tumors. ■ Patients being treated with Zometa should not be treated with

Reclast or other bisphosphonates.

Maternal/Child:

Category D: avoid pregnancy; may cause fetal harm. ■ Discontinue breast-feeding. ■ Not indicated for use in pediatric patients. Because of long-term retention in bone, zoledronic acid should be used in pediatric patients only when potential benefit outweighs potential risk. Has been used in pediatric patients with severe osteogenesis imperfecta; see manufacturer's prescribing information.

Elderly:

Response similar to that seen in younger patients. ■ Use with caution based on age-related impaired organ function and concomitant disease or other drug therapy. Monitor renal function closely. Elderly patients are at increased risk for acute renal failure. ■ Monitor fluid and electrolyte status. ■ Acute-phase reactions occur less frequently in the elderly; see Side Effects.

DRUG/LAB INTERACTIONS

Reclast and Zometa

Concurrent use with **loop diuretics** may increase risk of hypocalcemia or nephrotoxicity. ■ Concurrent use with **aminoglycosides** or **calcitonin** may have an additive hypocalcemic effect that may persist for a prolonged period. ■ Use caution when administered with other potentially **nephrotoxic drugs** (e.g., aminoglycosides, cisplatin, NSAIDs); the risk of renal deterioration is increased. Consider monitoring of SCr. ■ Use with caution when administered with **renally eliminated drugs** (e.g., digoxin). Possible development of renal impairment may lead to increased exposure of these drugs. Use caution and consider monitoring of SCr. ■ In vitro studies indicate that it does not inhibit microsomal CYP_{450} enzymes. ■ Concomitant administration of **drugs associated with ONJ** (e.g., bevacizumab, denosumab, everolimus, pazopanib, sorafenib, sunitinib, or corticosteroids) may increase the risk of ONJ.

Zometa

Does not interfere with any known primary cancer therapy. ■ Concurrent use with **thalidomide** does not result in a significant change in the pharmacokinetics of zoledronic acid or creatinine clearance; no dose adjustment indicated. ■ Effects may be antagonized by **calcium-containing preparations or vitamin D;** avoid use.

SIDE EFFECTS

Reclast and Zometa

Abdominal pain, anorexia, atypical femur fracture, conjunctivitis, constipation, dehydration, diarrhea, dyspnea, episcleritis, flu-like syndrome (e.g., arthralgias and/or bone pain, chills, fever, flushing, and myalgias), headache, hypersensitivity reactions (including rare case of anaphylaxis, angioedema, and urticaria), hypocalcemia (abdominal cramps, confusion, muscle spasms), hypomagnesemia, hypophosphatemia, hypotension, injection site reactions, nausea, ocular inflammation (e.g., iritis, uveitis, scleritis, orbital inflammation and edema), osteonecrosis (primarily of the jaw), rash, renal impairment, and vomiting. In addition to the previously noted side effects, an acute-phase reaction (e.g., chills, fatigue, fever, headache, influenza-like illness, or muscle, bone, or joint pain) and nausea and vomiting were reported. Symptoms may be significant and lead to dehydration. This acute-phase reaction may occur within the first 3 days, is usually mild to moderate, and lasts only a few days. However, in some patients the resolution of symptoms may take 7 to 14 days or longer.

Reclast

The most commonly reported side effects are arthralgia, fever, headache, myalgia, and pain in extremities. Other important side effects include diarrhea, eye inflammation, flu-like illness, nausea, and vomiting. In addition to the previously noted side effects, abdominal distension, anemia, asthenia, atrial fibrillation, back pain, dizziness, dyspepsia, fatigue, hypertension, lethargy, musculoskeletal stiffness, pain, paresthesia, peripheral edema, and vertigo have also been reported.

Zometa

The most commonly reported side effects are anemia, bone pain, constipation, dyspnea, fatigue, fever, nausea, and vomiting. In addition to the previously noted side effects, agitation, anxiety, bronchoconstriction, chest pain, confusion, cough, dysphagia, edema, granulocytopenia, hypokalemia, increased serum creatinine, pancytopenia, pleural effusion, pruritus, somnolence, thrombocytopenia, urinary tract infection, and weakness have occurred in 10% or more of patients. Fluid overload, hypokalemia, hypomagnesemia, and hypophosphatemia may occur more often with the use of concurrent fluid and diuretics.

Post-Marketing:

Acquired Fanconi syndrome; acute renal failure; angioneurotic edema; asthma exacerbation; atypical subtrochanteric and diaphyseal femoral fractures; blurred vision; bradycardia; bronchospasm; dehydration secondary to diuretic therapy, fever, or GI losses; dry mouth; hematuria; hyperesthesia; hyperkalemia; hypernatremia; hypersensitivity reactions (including anaphylactic reaction/shock, angioedema, bronchoconstriction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and urticaria); hypertension; hypocalcemia (cardiac arrhythmias, numbness, seizures, and tetany have occurred with severe hypocalcemia); hypophosphatemia; increased SCr; increased sweating; influenza-like illness (asthenia, fatigue or malaise, fever persisting for more than 30 days); interstitial lung disease (ILD) with positive rechallenge; musculoskeletal pain (severe); osteonecrosis (primarily of the jaw but also of other anatomic sites, including ankle, external auditory canal, femur, hip, humerus, knee, and wrist); proteinuria; and weight increase.

Overdose:

Clinically significant hypocalcemia (e.g., abdominal cramps; confusion; irregular heartbeats; muscle cramps in the hands, arms, feet, legs, or face; numbness and tingling around the mouth, fingertips, or feet), hypophosphatemia (e.g., unusual tiredness or weakness), and hypomagnesemia (e.g., muscle trembling or twitching) may occur.

Elevated SCr levels and renal tubular necrosis may occur with excessive dose or rate of administration.

ANTIDOTE

Reclast and Zometa

Keep physician informed of side effects. According to the manufacturer, no specific treatment was required in most cases of flu-like syndrome, GI symptoms, and infusion site reactions, and the symptoms subsided in 24 to 48 hours. Some side effects may respond to symptomatic treatment. IV fluids may be required for dehydration. Magnesium and phosphorus may require replacement if depletion is too severe. If mild, all will probably return toward normal in 7 to 10 days. For asymptomatic or mild to moderate hypocalcemia (6.5 to 8 mg/100 mL [1 dL] corrected for serum albumin), short-term calcium therapy (e.g., calcium gluconate) may be indicated. Discontinue drug for any symptoms of hypersensitivity or overdose. Discontinue for severe bone, joint, or muscle pain. Treat anaphylaxis and resuscitate as indicated.

Zometa

Monitor serum calcium and use vigorous IV hydration, with or without diuretics, for 2 to 3 days. Monitor intake and output to ensure adequacy and balance. Use short-term IV calcium therapy if indicated. Potassium phosphate and/or magnesium sulfate may be required to treat hypophosphatemia and hypomagnesemia.

Appendix A: Recommendations for the Safe Use and Handling of Cytotoxic Drugs

---

Numerous references are available on the topic of guidelines, recommendations, and regulations for handling antineoplastic and other hazardous agents.

The Department of Health and Human Services in the Centers for Disease Control and Prevention has publications and other references that cover all aspects of the topic at www.cdc.gov/niosh. Click on Hazards & Exposures, then click on Antineoplastic Agents, and finally on NIOSH Publications. Links to several informative documents can be found on this page, including *Preventing Occupational Exposure to Antineoplastic and Other Hazardous Drugs in Health Care Settings* and the *NIOSH List of Antineoplastic and Other Hazardous Drugs in Healthcare Settings, 2016*. The latter document discusses the criteria used to define hazardous drugs and places drugs into three different groups: (1) antineoplastic drugs, (2) nonantineoplastic drugs that meet one or more of the NIOSH criteria for a hazardous drug, and (3) drugs that primarily pose a reproductive risk to men and women who are actively trying to conceive and women who are pregnant or breast-feeding. This publication also provides general guidance on personal protective equipment and engineering controls when working with hazardous drugs in health care settings.

The United States Pharmacopeia published General Chapter <800> in the First Supplement to USP 39–NF 34. The purpose of this chapter is to describe practice and quality standards for handling hazardous drugs in health care settings and to help promote patient safety, worker safety, and environmental protection. The new general chapter defines processes intended to minimize the exposure to hazardous drugs in health care settings.

Other frequently cited guidelines on handling hazardous drugs are available from the American Society of Health-System Pharmacists, the Oncology Nursing Society, and the International Society of Oncology Pharmacy Practitioners.

Together these guidelines and regulations represent the recommendations of many diverse groups and have been established to promote not only patient safety but also worker safety and environmental protection.

Appendix B: FDA Pregnancy Categories

The FDA is no longer using these categories, but many drug monographs have not been updated in the prescribing information, so these categories will remain in the appendixes for now. The new categories include Reproductive Considerations, Pregnancy Considerations, and Breastfeeding Considerations. No drug should be used during pregnancy unless clearly needed and the risks to the fetus are outweighed by the benefits to the mother.

Category A Adequate studies have not demonstrated a risk to the fetus in any trimester.

Category B May have caused adverse effects in animals, but no adverse effects have been demonstrated in humans in any trimester, or no demonstrated risk in animals, but there are no adequate studies in pregnant women.

Category C Animal studies have shown an adverse effect, but there are no adequate studies in pregnant women or no animal studies and no studies in pregnant women.

Category D Definite fetal risks. May be given in spite of risks if needed in life-threatening conditions.

Category X Will cause fetal abnormalities. Risk of use outweighs benefits. Not recommended for use at any time during pregnancy. Consider alternatives before treating a pregnant woman.

Consider all men and women capable of conception when any drug in Category D or Category X is to be administered. Discuss birth control options to avoid pregnancy if a specific drug in these categories must be administered. Some drugs require birth control for months after all dosing is complete. Research complete information and keep patient informed.

Appendix C: U.S. Department of Health and Human Services, National Institutes of Health, National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE)

In Appendix C we have in the past incorporated the Common Toxicity Criteria (CTC) provided by the U.S. Department of Health and Human Services, the National Institutes of Health, and the National Cancer Institute. It was referred to throughout the text as the National Cancer Institute Common Toxicity Grading Criteria (NCI CTGC). This listing has been expanded and updated by these organizations and is too expansive to be included in an appendix. Web access to this material is available at www.cancer.gov. Search for CTCAE (Common Terminology Criteria for Adverse Events Version 5.0). Printed copies are available free of charge; call 1-800-4-CANCER (1-800-422-6237).

Appendix D: Information for Patients Receiving Immunosuppressive Agents

- Report allergic or sensitivity reactions you may have had to drugs or food.
- Report other medical problems you may have (e.g., exposure to chickenpox; herpes zoster; infections; bone marrow, heart, kidney, or liver problems).
- Provide a complete list of all medications you take, prescription and nonprescription.
- In most situations birth control is essential and may be required for both patient and partner. Nonhormonal birth control reduces the possibility of drug interactions, but compliance is imperative. If there is any possibility you or your partner may be pregnant, inform your physician promptly.
- Discontinue breast-feeding.
- Take only prescribed medication(s) in the exact amounts prescribed and at the times prescribed. This will help to maintain correct blood levels and avoid drug interactions.
- Confirm procedure if you should miss a dose. If any questions, notify physician.
- Confirm procedure for correct storage of your medication(s).
- Close monitoring by your physician is very important; keep all appointments and have all required lab work done on schedule. Your medications may interfere with some test results. Discuss with your physician.
- Do not take any immunizations without your physician's approval. Polio vaccine is especially virulent in your condition; request family members to defer immunization, and either avoid friends who have been immunized or wear a protective mask covering your nose and mouth while visiting. Live vaccines should be avoided.
- Dental procedures may need to be completed before starting therapy or deferred until therapy is completed. Use caution with your toothbrush, toothpicks, or dental floss. Alternate methods of dental hygiene may be necessary should your gums become tender, inflamed, or bleed.
- Review all side effects with your physician. Confirm those that may be a special problem for you and discuss solutions and expectations.
- Avoid anyone with an infection or fever. Report symptoms such as chills, fever, cough, hoarseness, lower back or side pain, painful or difficult urination. Take precautions when in crowded areas indoors, and consider wearing a mask.
- Wash hands before touching your eyes or the inside of your nose.
- Report unusual bleeding, bruising, black tarry stools, blood in urine, or pinpoint

red spots on your skin (petechiae).

- Report redness, swelling, or soreness in the mouth (symptoms of stomatitis).
- Report mild hair loss, nausea and vomiting, rash, tiredness, weakness.
- Avoid accidental cuts whenever possible (e.g., razors, fingernail and toenail clippers).
- Avoid contact sports in which you might be bruised or injured.
- Drink adequate amounts of fluids to prevent increases in serum uric acid concentrations. Allopurinol and/or alkalinization of urine may be required.
- Anesthesia during dental, surgical, or emergency treatment may be a problem. It is best to consult with your physician, but inform all health care professionals about the medications you are taking before they treat you in any way.

Appendix E: Recently Approved Drugs

- Difelikefalin (Korsuva)
- Terlipresssin (Terlivaz)
- Spesolimab (Spevigo)
- Sodium thiosulfate (Pedmark)
- Nivolumab and Relatlimab (Opdualag)

INDEX

Color type indicates generic drug name.
Italic type indicates drug categories and listings.

Anesthetics
    etomidate, 544–545
    fentanyl citrate, 569–574
    midazolam hydrochloride, 860–864
    propofol injection, 1089–1093
Angiogenesis inhibitors
    bevacizumab, 174–179
    bevacizumab-awwb, 174–179
    bevacizumab-bvzr, 174–179
    *ramucirumab**
Angiotensin II injection, **81–82**
Anidulafungin, **83–85**
Anifrolumab, **86–87**
Anjeso, 819–822
Anthracycline antineoplastic agents
    daunorubicin and cytarabine liposome for injection, 379–383
    daunorubicin citrate liposomal injection, 383–386
    daunorubicin hydrochloride, 383–386
    doxorubicin hydrochloride, 461–467

- *doxorubicin hydrochloride liposomal injection*, 461–467
- *epirubicin hydrochloride*, 497–502
- *idarubicin hydrochloride*, 695–697

Antiallergic agents
- *diphenhydramine hydrochloride*, 439–440
- *epinephrine hydrochloride*, 491–496

Anti-amyloid agents
- *aducanumab*, 20–21

Antianemic agents
- *darbepoetin alfa*, 374–379
- *epoetin alfa*, 503–508
- *ferric carboxymaltose injection*, 574–576
- *ferumoxytol*, 576–578
- *folic acid*, 601–602
- *iron dextran injection*, 743–745
- *iron sucrose*, 746–749
- *sodium ferric gluconate*, 1159–1161

Antianginal agents
- *dipyridamole*, 441–442
- *nitroglycerin IV*, 915–917

Antianxiety agents
- *diazepam*, 416–418
- *fentanyl citrate*, 569–574
- *lorazepam*, 804–807
- *midazolam hydrochloride*, 860–864
- *prochlorperazine edisylate*, 1083–1085
- *promethazine hydrochloride*, 1086–1088

Antiarrhythmic agents
- *adenosine*, 17–20
- *amiodarone*, 62–67
- *atropine*, 134–136
- *digoxin*, 420–425
- *diltiazem hydrochloride*, 430–433

    epinephrine hydrochloride, 491–496
    esmolol hydrochloride, 531–534
    glucagon, 640–642
    ibutilide fumarate, 692–694
    isoproterenol hydrochloride, 754–757
    lidocaine hydrochloride, 797–799
    magnesium sulfate, 812–815
    metoprolol tartrate, 850–852
    milrinone lactate, 865–867
    nicardipine hydrochloride, 912–915
    procainamide hydrochloride, 1080–1082
    propranolol hydrochloride, 1094–1097
    *quinidine gluconate injection**
    sotalol hydrochloride, 1163–1166
    verapamil hydrochloride, 1267–1269
Antibacterial agents
    amikacin, 50–53
    ampicillin, 75–78
    ampicillin/sulbactam, 78–80
    azithromycin, 147–150
    aztreonam, 150–153
    cefazolin sodium, 244–247
    cefepime hydrochloride, 248–251
    cefiderocol, 252–254
    cefotaxime sodium, 255–257
    cefotetan disodium, 258–260
    cefoxitin sodium, 261–264
    ceftaroline fosamil, 264–267
    ceftazidime, 268–271
    ceftazidime/avibactam, 272–276
    ceftolozane/tazobactam, 276–278
    ceftriaxone sodium, 279–282
    cefuroxime sodium, 283–285

ciprofloxacin, 305–311
clindamycin phosphate, 324–326
colistimethate sodium, 339
cytomegalovirus immune globulin intravenous (human), 360–361
dalbavancin, 363–365
daptomycin, 369–373
delafloxacin, 390–393
eravacycline, 519–521
ertapenem, 525–528
erythromycin lactobionate, 528–530
gentamicin sulfate, 636–639
imipenem-cilastatin, 704–707
imipenem, cilastatin, and relebactam, 708–711
immune globulin intravenous, 712–720
lefamulin, 770–772
levofloxacin, 784–790
linezolid, 800–804
meropenem, 823–826
meropenem and vaborbactam for injection, 827–829
metronidazole hydrochloride, 853–856
moxifloxacin hydrochloride, 879–883
nafcillin sodium, 890–893
omadacycline, 953–955
oritavancin, 962–964
penicillin G, 1020–1023
penicillin G aqueous, 1020–1023
piperacillin sodium and tazobactam sodium, 1051–1054
plazomicin, 1055–1057
rifampin, 1127–1131
sulfamethoxazole/trimethoprim, 1171–1174
tedizolid phosphate, 1186–1188
telavancin, 1188–1191
tigecycline for injection, 1217–1220

  - *tobramycin sulfate*, 1224–1227
  - *vancomycin hydrochloride*, 1254–1258
- *Antibiotics*
  - *metoclopramide hydrochloride*, 847–849
- *Anticholinergics/antispasmodics*
  - *atropine*, 134–136
  - *benztropine mesylate*, 171–173
  - *glycopyrrolate*, 645–647
- *Anticholinesterase muscle stimulants (cholinergic)*
  - *physostigmine salicylate*, 1047–1048

  - *insulin human injection (regular)*, 730–733
- *Antidiarrheals*
  - *octreotide acetate*, 942–945
- *Antidiuretics*
  - *chlorothiazide sodium*, 295
  - *desmopressin acetate*, 393–396
  - *terlipressin*, 1209–1210
  - *vasopressin injection*, 1258–1260
- *Antidotes*
  - *acetylcysteine*, 9–13
  - *atropine*, 134–136
  - *coagulation factor Xa (recombinant), inactivated-zhzo*, 336–338
  - *dexrazoxane*, 405–408
  - *dextrose*, 412–415
  - *digoxin immune fab*, 425–427
  - *epinephrine hydrochloride*, 491–496
  - *flumazenil*, 595–598
  - *fomepizole injection*, 603
  - *glucagon*, 640–642
  - *glucarpidase*, 643–645
  - *glycopyrrolate*, 645–647
  - *hydroxocobalamin*, 679–681
  - *idarucizumab*, 697–699
  - *leucovorin calcium*, 778–780
  - *levoleucovorin*, 790–794
  - *mesna*, 830–832
  - *naloxone hydrochloride*, 898–899
  - *neostigmine methylsulfate*, 910–912
  - *nitroprusside sodium*, 918–920
  - *physostigmine salicylate*, 1047–1048
  - *phytonadione*, 1048–1050

protamine sulfate, 1097–1099
prothrombin complex concentrate (human), 1104–1107
sodium thiosulfate, 1162
sugammadex, 1168–1170
Antidyskinetics
benztropine mesylate, 171–173
diphenhydramine hydrochloride, 439–440
Antiemetics
amisulpride, 68–69
aprepitant, 114–116
chlorpromazine hydrochloride, 298–301
dexamethasone sodium phosphate, 397–401
diphenhydramine hydrochloride, 439–440
fosaprepitant dimeglumine, 606–609
fosnetupitant and palonosetron, 614–617
granisetron hydrochloride, 654–656
lorazepam, 804–807
metoclopramide hydrochloride, 847–849
ondansetron hydrochloride, 959–962
prochlorperazine edisylate, 1083–1085
promethazine hydrochloride, 1086–1088
Antiepileptic agents
brivaracetam, 197–199
fosphenytoin sodium, 617–622
levetiracetam injection, 780–783
phenytoin sodium, 1040–1045
Antifibrinolytic agents
aminocaproic acid, 53–55
tranexamic acid, 1237–1239
Antifungals
amphotericin B, 70–74
amphotericin B lipid-based products, 70–74
anidulafungin, 83–85

- *caspofungin acetate*, 240–243
- *fluconazole*, 587–591
- *isavuconazonium sulfate*, 751–753
- *micafungin sodium*, 857–860
- *posaconazole*, 1068–1071
- *voriconazole*, 1288–1295

Antiglaucoma agents
- *acetazolamide sodium*, 7–9

Antigout agents
- *allopurinol sodium*, 39–41
- *pegloticase*, 1005–1007

Antihemophilic factor (human or recombinant), **88–98**

Antihemophilic factor recombinant (Fc fusion protein), **88–98**

Antihemophilic factor recombinant (PEGylated), **88–98**

Antihemophilic factor recombinant (PEGylated-aucl), **88–98**

Antihemophilic factor recombinant (porcine sequence), **88–98**

Antihemophilic factor recombinant (single chain), **88–98**

Antihemophilic factorAntihemophilic factor, Antihemophilic factor, von Willebrand factor, **99–104**

Antihemophilic products
- *antihemophilic factor (human, recombinant), all products*, 88–98
- *antihemophilic factor/von Willebrand factor*, 99–104
- *anti-inhibitor coagulant complex*, 105–107
- *factor IX (human)*, 549–552
- *factor IX (recombinant)*, 553–558
- *factor IX complex (human)*, 549–552

Antihemorrhagic agents
- *aminocaproic acid*, 53–55
- *antihemophilic factor (human, recombinant), all products*, 88–98
- *antihemophilic factor/von Willebrand factor*, 99–104
- *anti-inhibitor coagulant complex*, 105–107
- *coagulation factor VIIa (recombinant) RTS*, 331–333
- *coagulation factor X (human)*, 334–336

  - *coagulation factor XIII A-subunit**
  - *desmopressin acetate*, 393–396
  - *factor IX (human)*, 549–552
  - *factor IX (recombinant)*, 553–558
  - *factor IX complex (human)*, 549–552
  - *factor XIII concentrate (human)*, 559–561
  - *fibrinogen concentrate (human)*, 578–579
  - *oxytocin injection*, 969–971
  - *phytonadione*, 1048–1050
  - *prothrombin complex concentrate (human)*, 1104–1107
  - *tranexamic acid*, 1237–1239
  - *von Willebrand factor (recombinant)*, 1285–1287
  - *von Willebrand factor/coagulation factor VIII complex (human)*, 1282–1284
  - *VWF (recombinant)*, 1285–1287
  - *VWF/coagulation factor VIII complex (human)*, 1282–1284

Antihistamines
  - *diphenhydramine hydrochloride*, 439–440
  - *promethazine hydrochloride*, 1086–1088

Antihypercalcemic agents
  - *pamidronate disodium*, 987–990
  - *sodium chloride*, 1156–1159
  - *zoledronic acid*, 1300–1307

Antihyperkalemic agents
  - *calcium chloride*, 225–227

Antihypermagnesemic agents
  - *calcium chloride*, 225–227

Antihyperparathyroid agents
  - *calcitriol*, 222–225
  - *doxercalciferol*, 458–460
  - *paricalcitol*, 999–1002

Antihypertensives
  - *chlorothiazide sodium*, 295
  - *clevidipine butyrate*, 322–323

- *enalaprilat*, 486–489
- *epoprostenol sodium*, 508–512
- *fenoldopam mesylate*, 567–569
- *hydralazine hydrochloride*, 668–670
- *labetalol hydrochloride*, 764–766
- *nicardipine hydrochloride*, 912–915
- *nitroglycerin IV*, 915–917
- *nitroprusside sodium*, 918–920
- *sildenafil*, 1150–1152

Antihyperuricemic agents
- *allopurinol sodium*, 39–41
- *rasburicase*, 1108–1109

Antihypocalcemic agents
- *calcium chloride*, 225–227

Antihypoglycemic agents
- *glucagon*, 640–642
- *octreotide acetate*, 942–945

Antihypokalemic agents
- *potassium acetate and potassium chloride*, 1072–1075
- *potassium phosphate*, 1045–1046

Antihyponatremic agents
- *sodium acetate*, 1153–1154
- *sodium chloride*, 1156–1159

Antihypophosphatemics
- *phosphate*, 1045–1046
- *potassium phosphate*, 1045–1046
- *sodium phosphate*, 1045–1046

Anti-infectives
- *amikacin*, 50–53
- *amphotericin B*, 70–74
- *amphotericin B lipid-based products*, 70–74
- *ampicillin*, 75–78
- *ampicillin/sulbactam*, 78–80

anidulafungin, 83–85
azithromycin, 147–150
aztreonam, 150–153
caspofungin acetate, 240–243
cefazolin sodium, 244–247
cefepime hydrochloride, 248–251
cefotaxime sodium, 255–257
cefotetan disodium, 258–260
cefoxitin sodium, 261–264
ceftaroline fosamil, 264–267
ceftazidime, 268–271
ceftazidime/avibactam, 272–276
ceftolozane/tazobactam, 276–278
ceftriaxone sodium, 279–282
cefuroxime sodium, 283–285
cidofovir injection, 301–304
ciprofloxacin, 305–311
clindamycin phosphate, 324–326
colistimethate sodium, 339
cytomegalovirus immune globulin intravenous (human), 360–361
dalbavancin, 363–365
daptomycin, 369–373
delafloxacin, 390–393
eravacycline, 519–521
ertapenem, 525–528
erythromycin lactobionate, 528–530
fluconazole, 587–591
foscarnet sodium, 610–614
ganciclovir sodium, 627–630
gentamicin sulfate, 636–639
ibalizumab-uiyk, 682–683
imipenem-cilastatin, 704–707
immune globulin intravenous, 712–720

  - *isavuconazonium sulfate*, 751–753
  - *letermovir*, 773–777

fluorouracil, 598–600
gemcitabine hydrochloride, 630–635
*gemtuzumab ozogamicin**
idarubicin hydrochloride, 695–697
ifosfamide, 700–703
irinotecan hydrochloride, 734–743
irinotecan liposome injection, 734–743
isatuximab, 749–750
ixabepilone, 758–762
lurbinectedin, 808–809
*melphalan hydrochloride**
methotrexate sodium, 834–839
mitomycin, 868–870
mitoxantrone hydrochloride, 870–873
*moxetumomab pasudotox-tdfk**
necitumumab, 904–907

nelarabine, 907–909

nivolumab, 920–928

nivolumab and relatlimab, 928–930

obinutuzumab, 933–938

ofatumumab, 946–950

olaratumab, 951–952

oxaliplatin, 965–969

paclitaxel, 972–981

paclitaxel protein-bound particles for injectable suspension (albumin-bound), 972–981

palonosetron, 984–986

panitumumab, 991–994

pembrolizumab, 1008–1015

pemetrexed, 1016–1019

pentostatin, 1027–1029

pertuzumab, 1032–1036

polatuzumab vedotin-piiq, 1058–1062

porfimer sodium, 1063–1067

pralatrexate, 1076–1079

*ramucirumab**

rituximab products, 1132–1139

romidepsin, 1140–1143

sacituzumab govitecan, 1144–1145

tagraxofusp-erzs, 1182–1185

temozolomide, 1191–1196

temsirolimus, 1197–1200

teniposide, 1204–1207

thiotepa, 1213–1216

topotecan hydrochloride, 1234–1236

trastuzumab products, 1240–1244

trilaciclib, 1245–1246

vinblastine sulfate, 1270–1272

vincristine sulfate, 1273–1277

vincristine sulfate liposome injection, 1273–1277
vinorelbine, 1278–1281
Antineutropenic agents
filgrastim products, 580–584
sargramostim, 1146–1149
Antiparkinson agents
benztropine mesylate, 171–173
diphenhydramine hydrochloride, 439–440
Anti-PD-1 monoclonal antibodies
cemiplimab-rwlc, 286–289
nivolumab, 920–928
nivolumab and relatlimab, 928–930
Antiplatelet agents
cangrelor, 230–232
dipyridamole, 441–442
eptifibatide, 513–517
tirofiban hydrochloride, 1220–1223
Antipolyneuropathy agents
immune globulin intravenous, 712–720
Antiprotozoal agents
amphotericin B, 70–74
amphotericin B lipid-based products, 70–74
clindamycin phosphate, 324–326
metronidazole hydrochloride, 853–856
pentamidine isethionate, 1023–1024
sulfamethoxazole/trimethoprim, 1171–1174
Antipsoriatics
methotrexate sodium, 834–839
Antipsychotic agents
chlorpromazine hydrochloride, 298–301
prochlorperazine edisylate, 1083–1085
Antipyretics
acetaminophen, 4–7

ibuprofen, 687–690

Antiretroviral agents

ibalizumab-uiyk, 682–683

Antirheumatics

abatacept, 1–4

golimumab, 648–652

infliximab products, 723–729

methotrexate sodium, 834–839

rituximab products, 1132–1139

tocilizumab, 1228–1233

Antisense oligonucleotides

casimersen, 238–239

eteplirsen, 542–543

golodirsen injection, 652–654

Antithrombin III, **107–109**

Antithrombin recombinant, **109–111**

Antithrombotic agents

antithrombin III, 107–109

antithrombin recombinant, 109–111

eptifibatide, 513–517

tirofiban hydrochloride, 1220–1223

Anti-Thymocyte Globulin (Equine), 809–811

Anti-thymocyte globulin (rabbit), **112–114**

Antitoxins

bezlotoxumab, 179–181

Anti-tubercular agents

rifampin, 1127–1131

Antiulcer agents

famotidine, 561–563

Antivertigo agents

diphenhydramine hydrochloride, 439–440

Antiviral agents

acyclovir, 14–16

  - *cidofovir injection*, 301–304

Free radical scavengers

- *edaravone*, 480–481

Furosemide, **623–626**

Fusilev, 790–794

G

GABA A receptor positive modulators brexanolone, 195–197

Gamifant, 483–486

Gammagard Liquid, 712–720

Gammagard S/D, 712–720

Gammaked, 712–720

Gammaplex, 712–720

Gamunex-C, 712–720

Ganciclovir sodium, **627–630**

Ganzyk-RTU, 627–630

Gastric acid inhibitors

- *esomeprazole sodium*, 535–538
- *famotidine*, 561–563
- *pantoprazole sodium*, 994–997

Gastric sphincter relaxants

- *glucagon*, 640–642
- *metoclopramide hydrochloride*, 847–849

Gazyva, 933–938

G-CSF, 580–584

Gemcitabine hydrochloride, **630–635**

Gemtuzumab ozogamicin*

Gemzar, 630–635

General anesthetics

  etomidate, 544–545

  propofol injection, 1089–1093

Gene therapy

  onasemnogene abeparvovec-xioi, 956–958

Gentamicin sulfate, **636–639**

Giapreza, 81–82

GI stimulants

  metoclopramide hydrochloride, 847–849

GlucaGen, 640–642

Glucagon, **640–642**

Glucagon for Injection, 640–642

Glucarpidase, **643–645**

Glucose, 412–415

Glucose-elevating agents

  glucagon, 640–642

  octreotide acetate, 942–945

Glycoprotein GPIIb/IIIa receptor

  tirofiban hydrochloride, 1220–1223

Glycoprotein GPIIb/IIIa receptor antagonists

  eptifibatide, 513–517

Glycopyrrolate, **645–647**

GLYRX-PF, 645–647

Golimumab, **648–652**

Golodirsen injection, **652–654**

Granisetron hydrochloride, **654–656**

Granulocyte colony-stimulating factor (human)

  filgrastim products, 580–584

Granulocyte-macrophage colony-stimulating factor (human)

  - *sargramostim*, 1146–1149
- *Growth factors*
  - *palifermin*, 982–984
- *Growth hormone suppressants*
  - *octreotide acetate*, 942–945

H

- *H_2 antagonists*
  - *famotidine*, 561–563
- Halaven, 521–524
- *HDAC inhibitors*
  - *romidepsin*, 1140–1143
- Hectorol Injection, 458–460
- Helixate FS, 88–98
- *Hematinic agents*
  - *ferric carboxymaltose injection*, 574–576
  - *ferumoxytol*, 576–578
  - *iron dextran injection*, 743–745
  - *iron sucrose*, 746–749
  - *sodium ferric gluconate*, 1159–1161
- *Hematopoietic agents*
  - *darbepoetin alfa*, 374–379
  - *epoetin alfa*, 503–508
  - *filgrastim products*, 580–584
  - *sargramostim*, 1146–1149
- **Hemin**, **657–658**
- Hemofil M, 88–98
- *Hemorrhagic cystitis (prophylactic) agents*
  - *mesna*, 830–832
- *Hemostatics, systemic*
  - *aminocaproic acid*, 53–55
  - *antihemophilic factor*, 88–98

- *antihemophilic factor/von Willebrand factor*, 99–104
- *coagulation factor VIIa (recombinant) RTS*, 331–333
- *coagulation factor X (human)*, 334–336
- *factor IX (human)*, 549–552
- *factor IX complex (human)*, 549–552
- *fibrinogen concentrate (human)*, 578–579
- *prothrombin complex concentrate (human)*, 1104–1107
- *tranexamic acid*, 1237–1239

HepaGam B, 663–665

Heparin antagonists

- *protamine sulfate*, 1097–1099

Heparin sodium, **658–663**

Hepatitis B immune globulin intravenous (human), **663–665**

Herceptin, 1240–1244

Herpes simplex virus encephalitis agents

- *acyclovir*, 14

Herzuma, 1240–1244

Hespan, 666

Hetastarch, **666**

Hextend, 666

Histamine H_1 antagonists

- *cetirizine hydrochloride*, 289–290
- *promethazine hydrochloride*, 1086–1088

Histamine H_2 antagonists

- *famotidine*, 561–563

Hormones

- *angiotensin II injection (peptide)*, 81–82
- *desmopressin acetate*, 393–396
- *dexamethasone sodium phosphate*, 397–401
- *hydrocortisone sodium succinate*, 670–673
- *insulin human injection (regular)*, 730–733
- *levothyroxine sodium*, 794–796

    methylprednisolone sodium succinate, 842–846
    octreotide acetate, 942–945
    oxytocin injection, 969–971
    terlipressin, 1209–1210
    vasopressin injection, 1258–1260
5-HT$_3$ receptor antagonists
    fosnetupitant and palonosetron, 614–617
    granisetron hydrochloride, 654–656
    ondansetron hydrochloride, 959–962
    palonosetron, 984–986
Human Albumin Grifols 25%, 21–24
Human Granulocyte Colony-Stimulating Factor, 580–584
Humate-P, 99–104
Humulin R, 730–733
Hycamtin, 1234–1236
Hydantoins
    fosphenytoin sodium, 617–622
    phenytoin sodium, 1040–1045
Hydralazine hydrochloride, **668–670**
Hydrocortisone sodium succinate, **670–673**
Hydromorphone hydrochloride, **674–678**
Hydroxocobalamin, **679–681**
Hypnotic/sedatives, CNS depressants
    dexmedetomidine hydrochloride, 402–405
    diazepam, 416–418
    diphenhydramine hydrochloride, 439–440
    lorazepam, 804–807
    midazolam hydrochloride, 860–864
    pentobarbital sodium, 1025–1026
    phenobarbital sodium, 1036–1038
    promethazine hydrochloride, 1086–1088
    propofol injection, 1089–1093

I

Ibalizumab-uiyk, **682–683**
Ibandronate sodium, **684–686**
Ibuprofen, **687–690**
Ibuprofen lysine, **690–692**
Ibutilide fumarate, **692–694**
Idamycin PFS, 695–697
Idarubicin hydrochloride, **695–697**
Idarubicin PFS, 695–697
Idarucizumab, **697–699**
IDELVION, 553–558
IDR, 695–697
Ifex, 700–703
Ifosfamide, **700–703**
IGIV, 712–720
IGIV-ifas, 712–720
Imipenem-cilastatin, **704–707**
Imipenem, cilastatin, and relebactam, **708–711**
Immune checkpoint inhibitor
  nivolumab and relatlimab, 928–930
Immune globulin intravenous, **712–720**
Immune globulin intravenous-ifas, 712–720
Immune globulins
  aducanumab, 20–21
  anifrolumab, 86–87
Immunizing agents
  cytomegalovirus immune globulin intravenous (human), 360–361
  hepatitis B immune globulin intravenous (human), 663–665
  immune globulin intravenous, 712–720
  immune globulin IV (passive), 712–720
  Rh_0(D) immune globulin intravenous (human), 1122–1126
Immunomodulators

- *aldesleukin*, 24–30
- *alemtuzumab*, 31–38
- *natalizumab*, 900–904

Immunosuppressive agents
- *anti-thymocyte globulin (rabbit)*, 112–114
- *basiliximab*, 154–156
- *belatacept (selective T-cell costimulation blocker)*, 157–161
- *cyclosporine*, 349–353
- *dexamethasone sodium phosphate*, 397–401
- *lymphocyte immune globulin*, 809–811
- *mycophenolate mofetil hydrochloride*, 886–890
- *panitumumab*, 991–994
- *tacrolimus*, 1175–1181

Indocin IV, 721–722

Indomethacin sodium, **721–722**

InFeD, 743–745

Inflammatory bowel disease agents
- *infliximab products*, 723–729

Inflectra, 723–729

Infliximab, **723–729**

Infliximab-abda, **723–729**

Infliximab-axxq, **723–729**

Infliximab-dyyb, **723–729**

Infliximab-qbtx, **723–729**

Influenza virus neuraminidase inhibitors
- *peramivir*, 1029–1031

Infufer, 743–745

Infugem, 630–635

Infuvite Adult, 884

Infuvite Pediatric, 884

Injectafer, 574–576

Inotropic agents
- *digoxin*, 420–425

  - *dobutamine hydrochloride*, 443–445
  - *dopamine hydrochloride*, 454–457
  - *isoproterenol hydrochloride*, 754–757
  - *milrinone lactate*, 865–867

Insulin human injection (regular), **730–733**

Insulin-like growth factor-1 (IGR-IR)
  - *teprotumumab-trbw*, 1207–1209

Integrilin, 513–517

Integrin receptor antagonists
  - *vedolizumab*, 1264–1266

Interferon receptor antagonists
  - *anifrolumab*, 86–87

Interleukin-5 antagonists
  - *reslizumab*, 1116

Interleukin-2 Recombinant, 24–30

Intralipid 20% & 30%, 563–567

Intravenous fat emulsion, 563–567

Invanz, 525–528

Irinotecan hydrochloride, **734–743**

Irinotecan liposome injection, **734–743**

Iron dextran injection, **743–745**

Iron sucrose, **746–749**

Iron supplements
  - *ferric carboxymaltose injection*, 574–576
  - *ferumoxytol*, 576–578
  - *iron dextran injection*, 743–745
  - *iron sucrose*, 746–749
  - *sodium ferric gluconate*, 1159–1161

Isatuximab, **749–750**

Isavuconazonium sulfate, **751–753**

Isoproterenol hydrochloride, **754–757**

Istodax, 1140–1143

Isuprel, 754–757

Ixabepilone, **758–762**

Ixempra Kit, 758–762

Ixifi, 723–729

IXINITY, 553–558

J

Jevtana, 213–217

Jivi, 88–98

K

Kabiven, 1099–1104

Kanjinti, 1240–1244

Kappa opioid receptor agonist

- *difelikefalin*, 419

Kcentra, 1104–1107

Kefzol, 244–247

Kengreal, 230–232

Kepivance, 982–984

Keppra, 780–783

Ketorolac tromethamine, **762–764**

Keytruda, 1008–1015

KGF, 982–984

Khapzory, 790–794

Kinase inhibitors

- *temsirolimus*, 1197–1200

Koate DVI, 88–98

Kogenate FS, 88–98

Kogenate FS Bio-Set, 88–98

Korsuva, 419

Kovaltry, 88–98

Kovaltry Bio-Set, 88–98

Krystexxa, 1005–1007

L

Labetalol hydrochloride, **764–766**
Lacosamide, **767–770**
Lanoxin, 420–425
Lanoxin Pediatric, 420–425
Lartruvo, 951–952
Lasix, 623–626
Lefamulin, **770–772**
Lemtrada, 31–38
Letermovir, **773–777**
Leucovorin calcium, **778–780**
Leucovorin Calcium PF, 778–780
Leukine, 1146–1149
Leustatin, 319–321
Levaquin, 784–790
Levarterenol Bitartrate, 930–932
Levetiracetam injection, **780–783**
Levofloxacin, **784–790**
Levoleucovorin, **790–794**
Levophed, 930–932
Levothyroxine sodium, **794–796**
Libtayo, 286–289
Lidocaine hydrochloride, **797–799**
Lidocaine PF, 797–799
Lincosamides
  clindamycin phosphate, 324–326
Linezolid, **800–804**
Lipid-based products
  amphotericin B, 70–74
  daunorubicin hydrochloride, 383–386
  doxorubicin hydrochloride, 461–467
  irinotecan hydrochloride, 734–743

vincristine sulfate, 1273–1277

Lipoglycopeptides

dalbavancin, 363–365

oritavancin, 962–964

telavancin, 1188–1191

Liposyn II 10% & 20%, 563–567

L.M.D. 10%, 410–411

Loop diuretics

bumetanide, 200–201

furosemide, 623–626

Lopressor, 850–852

Lorazepam, **804–807**

Lorazepam PF, 804–807

L-Thyroxine, 794–796

Luminal Sodium, 1036–1038

Lumoxiti*

Lupus erythematosus agents

belimumab, 161–164

Lurbinectedin, **808–809**

Lymphocyte immune globulin, **809–811**

Lyophilized Cytoxan, 345–349

M

Macrolide antibiotics

azithromycin, 147–150

erythromycin lactobionate, 528–530

Magnesium sulfate, **812–815**

Mannitol, **816–819**

Marqibo, 1273–1277

Maxipime, 248–251

Mefoxin, 261–264

Meloxicam injection, **819–822**

Melphalan hydrochloride*
Meropenem, **823–826**
Meropenem and vaborbactam for injection, **827–829**
Merrem I.V., 823–826
Mesna, **830–832**
Mesnex, 830–832
Methergine, 840–841
Methocarbamol, **832**
Methotrexate PF, 834–839
Methotrexate sodium, **834–839**
Methylergonovine maleate, **840–841**
Methylprednisolone sodium succinate, **842–846**
Metoclopramide hydrochloride, **847–849**
Metoprolol tartrate, **850–852**
Metro IV, 853–856
Metronidazole hydrochloride, **853–856**
Micafungin sodium, **857–860**
Midazolam HCl PF, 860–864
Midazolam hydrochloride, **860–864**
Milrinone lactate, **865–867**
Mitomycin, **868–870**
Mitoxantrone hydrochloride, **870–873**
Monobactam antibiotics
  aztreonam, 150–153
Monoclonal antibodies
  aducanumab, 20–21
  alemtuzumab, 31–38
  atezolizumab (anti-PD-L1), 128–134
  avelumab (anti-PD-L1), 139–143
  basiliximab, 154–156
  belimumab, 161–164
  bevacizumab products, 174–179
  bezlotoxumab, 179–181

  cemiplimab-rwlc (anti-PD-1), 286–289
  cetuximab, 291–295
  dinutuximab, 434–438
  eculizumab, 475–480

  eptinezumab-jjmr, 518
  *gemtuzumab ozogamicin**
  golimumab, 648–652
  ibalizumab-uiyk, 682–683
  idarucizumab, 697–699
  infliximab products, 723–729
  isatuximab (anti CD-38), 749–750
  *moxetumomab pasudotox-tdfk**
  natalizumab, 900–904
  necitumumab, 904–907
  nivolumab, 920–928
  obinutuzumab (anti-CD20), 933–938
  ocrelizumab (anti-CD20), 939–942
  ofatumumab, 946–950
  olaratumab, 951–952
  panitumumab, 991–994
  pembrolizumab, 1008–1015
  pertuzumab, 1032–1036
  *ramucirumab**
  ravulizumab-cwvz, 1110–1114
  reslizumab, 1116
  rituximab, 1132–1139
  spesolimab, 1166–1167
  teprotumumab-trbw, 1207–1209
  tocilizumab, 1228–1233
  trastuzumab products, 1240–1244
  vedolizumab, 1264–1266
Mononine, 549–552

Morphine sulfate, **874–878**
Moxetumomab pasudotox-tdfk*
Moxifloxacin hydrochloride, **879–883**
MTC, 868–870
MTX, 834–839
Multivitamin infusion, **884**
Muscle relaxants
  cisatracurium besylate, 311–315
  dantrolene sodium, 366–368
  diazepam, 416–418
  lorazepam, 804–807
  methocarbamol, 832
  midazolam hydrochloride, 860–864
  vecuronium bromide, 1261–1263
Mutamycin, 868–870
Mvasi, 174–179
M.V.I.-12, 884
M.V.I. Adult, 884
M.V.I. Pediatric, 884
Mycamine, 857–860
Mycophenolate mofetil hydrochloride, **886–890**
Mylotarg*
Myxredlin, 730–733

N

Nafcillin sodium, **890–893**
Nalbuphine hydrochloride, **893–897**
Nallpen, 890–893
Naloxone hydrochloride, **898–899**
Narcotic analgesics, agonist/antagonists
  buprenorphine hydrochloride, 202–205
  butorphanol tartrate, 206–208

nalbuphine hydrochloride, 893–897
Narcotic analgesics, agonists/CNS depressants
  fentanyl citrate, 569–574
  hydromorphone hydrochloride, 674–678
  morphine sulfate, 874–878
Narcotic antagonists
  naloxone hydrochloride, 898–899
Natalizumab, **900–904**
Navelbine, 1278–1281
Necitumumab, **904–907**
Nelarabine, **907–909**
Nembutal Sodium, 1025–1026
Neonatal Fc receptor antagonists
  efgartigimod alfa, 482
NeoProfen, 690–692
Neostigmine methylsulfate, **910–912**
Neo-Synephrine, 1038–1040
Neupogen, 580–584
Neuromuscular blockade reversal agents
  sugammadex, 1168–1170
Neuromuscular blocking agents (nondepolarizing)
  cisatracurium besylate, 311–315
  vecuronium bromide, 1261–1263
Nexium IV, 535–538
Nexterone, 62–67
Nexviazyme, 137–138
Nicardipine hydrochloride, **912–915**
Nimbex, 311–315
Nimbex PF, 311–315
Nipent, 1027–1029
Nipride RTU, 918–920
Nitroglycerin IV, **915–917**
Nitropress, 918–920

Nitroprusside sodium, **918–920**

Nivestym, 580–584

Nivolumab, **920–928**

Nivolumab and relatlimab, **928–930**

Nondepolarizing neuromuscular blocker antagonists

- *neostigmine methylsulfate*, 910–912

Nonsteroidal anti-inflammatory agents

- *ibuprofen*, 687–690
- *ibuprofen lysine*, 690–692
- *ketorolac tromethamine*, 762–764
- *meloxicam injection*, 819–822

Norcuron, 1261–1263

Norepinephrine bitartrate, **930–932**

Normal saline, 1156–1159

Normal serum albumin (human), 21–24

Nouress, 354–357

Novantrone, 870–873

Novoeight, 88–98

Novolin ge Toronto, 730–733

NovoSeven RT, 331–333

Noxafil, 1068–1071

NSAIDs

- *ibuprofen*, 687–690
- *ibuprofen lysine*, 690–692
- *ketorolac tromethamine*, 762–764
- *meloxicam injection*, 819–822

Nubain, 893–897

Nulojix, 157–161

Nutrilipid 20%, 563–567

Nutritional products (supplements)

- *calcium chloride*, 225–227
- *calcium gluconate*, 227–230
- *dextrose*, 412–415

fat emulsion, intravenous, 563–567
fish oil triglycerides injectable emulsion, 584–587
folic acid, 601–602
multivitamin infusion, 884
potassium acetate and potassium chloride, 1072–1075
potassium phosphate, 1045–1046
protein amino acids, dextrose, fat emulsion, and electrolytes, 1099–1104
sodium acetate, 1153–1154
sodium bicarbonate, 1154–1156
sodium chloride, 1156–1159
thiamine hydrochloride, 1211–1212
Nuwiq, 88–98
Nuzyra, 953–955

O

Obinutuzumab, **933–938**

Onxol, 972–981

Opdivo, 920–928

Opdualag, 928–930

Opioid analgesics, CNS depressants

- *fentanyl citrate*, 569–574
- *hydromorphone hydrochloride*, 674–678
- *morphine sulfate*, 874–878

Orbactiv, 962–964

Orencia, 1–4

Oritavancin, **962–964**

Osmitrol, 816–819

Oxaliplatin, **965–969**

Oxazolidinones

- *linezolid*, 800–804
- *tedizolid phosphate*, 1186–1188

Oxytocics

- *methylergonovine maleate*, 840–841
- *oxytocin injection*, 969–971

Oxytocin injection, **969–971**

P

Pacerone, 62–67

Paclitaxel, **972–981**

Paclitaxel protein-bound particles for injectable suspension (albumin-bound), **972–981**

Palifermin, **982–984**

Palonosetron, **984–986**

Pamidronate disodium, **987–990**

Panhematin, 657–658

Panitumumab, **991–994**

Pantoprazole sodium, **994–997**

Panzga (IGIV-ifas), 712–720
Papaverine hydrochloride, **998–999**
Paricalcitol, **999–1002**
Parsabiv, 539–541
Patent ductus arteriosus agents
  ibuprofen lysine, 690–692
  indomethacin sodium, 721–722
Patisiran, **1002–1004**
Pedmark, 1162
Pegloticase, **1005–1007**
Pembrolizumab, **1008–1015**
Pemetrexed, **1016–1019**
Penicillin(s)
  ampicillin sodium, 75–78
  ampicillin/sulbactam, 78–80
  nafcillin sodium, 890–893
  penicillin G potassium and sodium, 1020–1023
  piperacillin sodium and tazobactam sodium, 1051–1054
Penicillin and beta-lactamase inhibitors
  ampicillin/sulbactam, 78–80
  piperacillin sodium and tazobactam sodium, 1051–1054
Penicillin G aqueous, **1020–1023**
Penicillin G Potassium, 1020–1023
Penicillin G Sodium, 1020–1023
Pentamidine isethionate, **1023–1024**
Pentobarbital sodium, **1025–1026**
Pentostatin, **1027–1029**
Pepcid, 561–563
Peptide hormones
  angiotensin II injection, 81–82
Peramivir, **1029–1031**
Perikabiven, 1099–1104
Perjeta, 1032–1036

Persantine, 441–442

Pertuzumab, **1032–1036**

Pfizerpen, 1020–1023

Pharmorubicin PFS, 497–502

Phenergan, 1086–1088

Phenobarbital sodium, **1036–1038**

Phenothiazines

- *chlorpromazine hydrochloride*, 298–301
- *prochlorperazine edisylate*, 1083–1085
- *promethazine hydrochloride*, 1086–1088

Phenylephrine hydrochloride, **1038–1040**

Phenytoin sodium, **1040–1045**

Phosphate, **1045–1046**

Phosphate, Potassium, 1045–1046

Phosphate replacement products

- *phosphate*, 1045–1046
- *sodium phosphate*, 1045–1046

Phosphate, Sodium, 1045–1046

Photofrin, 1063–1067

Photosensitizing agents

- *porfimer sodium*, 1063–1067

Physostigmine salicylate, **1047–1048**

Phytonadione, **1048–1050**

Piperacillin sodium and tazobactam sodium, **1051–1054**

Pitocin, 969–971

Plasbumin 5%, 20%, 25%, 21–24

Plasma protein(s)

- *albumin*, 21–24
- *antithrombin III (human)*, 107–109
- *antithrombin recombinant*, 109–111

Plasma protein fractions

- *albumin (human)*, 21–24

Plasma volume expanders

  - *albumin (human)*, 21–24
  - *dextran high molecular weight*, 410–411
  - *hetastarch*, 666

Platelet aggregation inhibitors
  - *cangrelor*, 230–232
  - *dipyridamole*, 441–442
  - *eptifibatide*, 513–517
  - *tirofiban hydrochloride*, 1220–1223

Platelet count stimulators
  - *immune globulin intravenous*, 712–720
  - *Rh_0(D) immune globulin intravenous (human)*, 1122–1126

Plazomicin, **1055–1057**

P/NK1 receptor antagonists
  - *aprepitant*, 114–116
  - *fosaprepitant dimeglumine*, 606–609

Polatuzumab vedotin-piiq, **1058–1062**

Polivy, 1058–1062

Porfimer sodium, **1063–1067**

Porphyrin inhibitors
  - *hemin*, 657–658

Portrazza, 904–907

Posaconazole, **1068–1071**

Potassium acetate and potassium chloride, **1072–1075**

Potassium Penicillin G, 1020–1023

Potassium phosphate, 1045–1046

Potassium replacement products
  - *potassium acetate and potassium chloride*, 1072–1075
  - *potassium phosphate*, 1045–1046

Pralatrexate, **1076–1079**

Praxbind, 697–699

Precedex, 402–405

Prevymis, 773–777

Primacor, 865–867
Primaxin, 704–707
Privigen, 712–720
Procainamide hydrochloride, **1080–1082**
Prochlorperazine edisylate, **1083–1085**
Procrit, 503–508
Procytox, 345–349
Proferdex, 743–745
Profilnine SD, 549–552
Prograf, 1175–1181
Proleukin, 24–30
Promethazine hydrochloride, **1086–1088**
Propofol injection, **1089–1093**
Propranolol hydrochloride, **1094–1097**
Prostaglandin(s)
  alprostadil, 42–43
  epoprostenol sodium, 508–512
Prostaglandin E_1, 42–43
Prostaglandin inhibitors
  indomethacin sodium, 721–722
Prostin VR Pediatric, 42–43
Protamine sulfate, **1097–1099**
Proteasome inhibitors
  bortezomib, 187–194
Protein amino acids, dextrose, fat emulsion, and electrolytes, **1099–1104**
Protein C1 inhibitors
  C1 esterase inhibitor (human or recombinant), 209–212
Protein inhibitors
  C1 esterase inhibitor (human or recombinant), 209–212
Prothrombin complex agents
  anti-inhibitor coagulant complex, 105–107
  factor IX complex (human), 549–552

    prothrombin complex concentrate (human), 1104–1107

Prothrombin complex concentrate (human), **1104–1107**

Protonix IV, 994–997

Proton pump inhibitors

    esomeprazole sodium, 535–538

    pantoprazole sodium, 994–997

Pulmonary antihypertensives

    epoprostenol sodium, 508–512

Pulmonary edema (adjunct) agents

    morphine sulfate, 874–878

Q

Quinidine gluconate injection*

Quzyttir, 289–290

R

Radicava, 480–481

Ramucirumab*

Rapivab, 1029–1031

Rasburicase, **1108–1109**

Ravulizumab-cwvz, **1110–1114**

Recarbrio, 708–711

Receptor antagonists

    aprepitant, 114–116

    fosaprepitant dimeglumine, 606–609

Reclast, 1300–1307

Recombinant antihemophilic factor [Fc fusion protein], 88–98

Recombinant antihemophilic factor [PEGylated], 88–98

Recombinant antihemophilic factor [PEGylated-aucl], 88–98

Recombinant antihemophilic factor [porcine sequence], 88–98

Recombinant antihemophilic factor [single chain], 88–98

Recombinant human erythropoietin agents

    darbepoetin alfa, 374–379
    epoetin alfa, 503–508
Recombinant interleukin-2 agents
    aldesleukin, 24–30
Recombinant monoclonal antibodies
    bevacizumab products, 174–179
    cetuximab, 291–295
Recombinate, 88–98
Reglan, 847–849
Relaxant binding agents (selective)
    sugammadex, 1168–1170
Relaxants, skeletal muscle
    cisatracurium besylate, 311–315
    dantrolene sodium, 366–368
    diazepam, 416–418
    lorazepam, 804–807
    methocarbamol, 832
    midazolam hydrochloride, 860–864
    vecuronium bromide, 1261–1263
Relaxants, smooth muscle (uterine)
    magnesium sulfate, 812–815
Relaxants, smooth muscle (vascular)
    alprostadil, 42–43
    milrinone lactate, 865–867
Releuko, 580–584
Remdesivir, **1114–1116**
Remicade, 723–729
Renflexis, 723–729
Reslizumab, **1116**
Respiratory stimulant adjuncts
    aminophylline, 56–61
    caffeine citrate, 217–219
Retacrit, 503–508

Retavase, 1118–1121

Reteplase recombinant, **1118–1121**

Retrovir, 1296–1299

Revatio, 1150–1152

Reversal neuromuscular blockade agents

  sugammadex, 1168–1170

Revonto, 366

Rheomacrodex, 410–411

Rh_o(D)-IGIV, 1122–1126

Rh_o(D) immune globulin intravenous (human), **1122–1126**

Rhophylac, 1122–1126

Riabni, 1132–1139

RiaSTAP, 578–579

Rifadin, 1127–1131

Rifampin, **1127–1131**

Rituxan, 1132–1139

Rituximab, **1132–1139**

Rituximab-abbs, **1132–1139**

Rituximab-arrx, **1132–1139**

Rituximab-pvvr, **1132–1139**

RIXUBIS, 553–558

Robaxin, 832

Rocephin, 279–282

Romazicon, 595–598

Romidepsin, **1140–1143**

r-PA, 1118–1121

rt-PA, 44–50

Ruconest, 209–212

Ruxience, 1132–1139

Ryanodex, 366

S

Sacituzumab govitecan, **1144–1145**

Salt replacement products

  sodium acetate, 1153–1154

  sodium chloride, 1156–1159

Sandimmune, 349–353

Sandostatin, 942–945

Saphnelo, 86–87

Sarclisa, 749–750

Sargramostim, **1146–1149**

Sedative/hypnotic CNS depressants

  dexmedetomidine hydrochloride, 402–405

  diazepam, 416–418

  diphenhydramine hydrochloride, 439–440

  lorazepam, 804–807

  midazolam hydrochloride, 860–864

  pentobarbital sodium, 1025–1026

  phenobarbital sodium, 1036–1038

  promethazine hydrochloride, 1086–1088

  propofol injection, 1089–1093

Selective relaxant binding agents

  sugammadex, 1168–1170

Selective T-cell costimulation blockers

  abatacept, 1–4

  belatacept, 157–161

Serum albumin, 21–24

Sildenafil, **1150–1152**

Simponi Aria, 648–652

Simulect, 154–156

siRNA

  patisiran, 1002–1004

Sivextro, 1186–1188

SMZ-TMP, 1171–1174

Sodium acetate, **1153–1154**

Sodium acetazolamide, 7–9
Sodium ampicillin, 75–78
Sodium ampicillin/sodium sulbactam, 78–80
Sodium bicarbonate, **1154–1156**
Sodium cefazolin, 244–247
Sodium cefotaxime, 255–257
Sodium cefoxitin, 261–264
Sodium ceftriaxone, 279–282
Sodium cefuroxime, 283–285
Sodium chloride, **1156–1159**
Sodium dantrolene, 366–368
Sodium epoprostenol, 508–512
Sodium ferric gluconate complex, **1159–1161**
Sodium foscarnet, 610–614
Sodium fosphenytoin, 617–622
Sodium ganciclovir, 627–630
Sodium levothyroxine, 794–796
Sodium luminal, 1036–1038
Sodium methotrexate, 834–839
Sodium micafungin, 857–860
Sodium nafcillin, 890–893
Sodium nembutal, 1025–1026
Sodium nitroprusside, 918–920
Sodium pantoprazole, 994–997
Sodium penicillin G, 1020–1023
Sodium pentobarbital, 1025–1026
Sodium phenobarbital, 1036–1038
Sodium phenytoin, 1040–1045
Sodium phosphate, 1045–1046
Sodium porfimer, 1063–1067
Sodium thiosulfate, **1162**
Sodium valproate, 1246–1253
Soliris, 475–480

Solu-Cortef, 670–673

Solu-Medrol, 842–846

Sotalol hydrochloride, **1163–1166**

Spesolimab, **1166–1167**

Spevigo, 1166–1167

Stadol, 206–208

Stadol PF, 206–208

Stimulants, anticholinesterase (cholinergic) muscle

- *neostigmine methylsulfate*, 910–912
- *physostigmine salicylate*, 1047–1048

Stimulants, central nervous system

- *caffeine citrate*, 217–219

Stimulants, smooth muscle

- *metoclopramide hydrochloride*, 847–849

Substance P/NK1 receptor antagonists

- *aprepitant*, 114–116
- *fosaprepitant dimeglumine*, 606–609
- *fosnetupitant and palonosetron*, 614–617

Substituted benzimidazoles

- *esomeprazole sodium*, 535–538
- *pantoprazole sodium*, 994–997

Sugammadex, **1168–1170**

Sulfamethoxazole and trimethoprim, **1171–1174**

Sulfonamides

- *sulfamethoxazole/trimethoprim*, 1171–1174

Sympathomimetic bronchodilators

- *ephedrine sulfate*, 490
- *epinephrine hydrochloride*, 491–496
- *isoproterenol hydrochloride*, 754–757

This chart is not all inclusive. It is based on manufacturer's recommendations and Trissel's.

KEY

C	**= Compatible[a]**
W	**= Compatible in water not NS**
D2½W	**= 2½% Dextrose in water**
D5W	**= 5% Dextrose in water**
D10W	**= 10% Dextrose in water**
D5/¼NS	**= 5% Dextrose in ¼ normal saline**
D5/½NS	**= 5% Dextrose in ½ normal saline**
D5NS	**= 5% Dextrose in normal saline**
NS	**= Normal saline**

½NS	**= ½ Normal saline**
R	**= Ringer's solution**
LR	**= Lactated Ringer's solution**
D5R	**= 5% Dextrose in Ringer's solution**
D5LR	**= 5% Dextrose in Lactated Ringer's solution**
Dextran 6%/D5W/NS	**= Dextran 6% in D5W or normal saline**
Fruc 10%/W/NS	**= Fructose 10% in water or normal saline**
Invert sug 10%/W/NS	**= Invert sugar 10% in water or normal saline**
Na Lactate ⅙ M	**= Sodium lactate ⅙ M**
1	**= Stable for 1 hour**
2	**= Stable for 2 hours**
4	**= Stable for 4 hours**
6	**= Stable for 6 hours**
10	**= Stable for 10 hours**
P	**= Preferred diluent**

[a] *Compatibility in various concentrations may vary; consult pharmacist.*
